Decisions about which APs are rogues are made manually on the Rogue AP monitor page. For detailed information, see [Wireless network monitoring on page 1145](#).

Suppressing rogue APs

When you have declared an AP to be a rogue, you have the option of suppressing it. To suppress an AP, the FortiGate WiFi controller sends reset packets to the rogue AP. Also, the MAC address of the rogue AP is blocked in the firewall policy. You select the suppression action on the Rogue AP monitor page. For more information, see [Wireless network monitoring on page 1145](#).

Rogue suppression is available only when there is a radio dedicated to scanning. It will not function during background scanning for spectrum analysis.

Wireless Intrusion Detection (WIDS)

You can create a WIDS profile to enable several types of intrusion detection:

- Unauthorized Device Detection
- Rogue/Interfering AP Detection
- Ad-hoc Network Detection and Containment
- Wireless Bridge Detection
- Misconfigured AP Detection
- Weak WEP Detection
- Multi Tenancy Protection
- MAC OUI Checking

For more information, see [Protecting the WiFi network on page 1140](#).

Authentication

Wireless networks usually require authenticated access. FortiOS authentication methods apply to wireless networks the same as they do to wired networks because authentication is applied in the firewall policy.

The types of authentication that you might consider include:

- user accounts stored on the FortiGate
- user accounts managed and verified on an external RADIUS, LDAP or TACACS+ server
- Windows Active Directory authentication, in which users logged on to a Windows network are transparently authenticated to use the wireless network.

This FortiWiFi and FortiAP Configuration Guide provides some information about each type of authentication, but more detailed information is available in the Authentication chapter of the FortiOS Handbook.

What all of these types of authentication have in common is the definition of user groups to specify who is authorized. For each wireless LAN, you will create a user group and add to it the users who can use the WLAN. In the identity-based firewall policies that you create for your wireless LAN, you will specify this user group.

Some access points, including FortiWiFi units, support MAC address filtering. You should not rely on this alone for authentication. MAC addresses can be “sniffed” from wireless traffic and used to impersonate legitimate clients.

Wireless networking equipment

Fortinet produces two types of wireless networking equipment:

- [FortiWiFi units](#), which are FortiGate units with a built-in wireless access point/client
- [FortiAP units](#), which are wireless access points that you can control from any FortiGate unit that supports the WiFi Controller feature.

FortiWiFi units

A FortiWiFi unit can:

- Provide an access point for clients with wireless network cards. This is called Access Point mode, which is the default mode.
- or**
- Connect the FortiWiFi unit to another wireless network. This is called Client mode. A FortiWiFi unit operating in client mode can only have one wireless interface.

or

- Monitor access points within radio range. This is called Monitoring mode. You can designate the detected access points as Accepted or Rogue for tracking purposes. No access point or client operation is possible in this mode. But, you can enable monitoring as a background activity while the unit is in Access Point mode.

The Products section of the Fortinet web site (www.fortinet.com) provides detailed information about the FortiWiFi models that are currently available.

FortiAP units

FortiAP units are thin wireless access points are controlled by either a FortiGate unit or FortiCloud service.

FortiAP is a family of Indoor, Outdoor and Remote Access Point models supporting the latest single, dual, and triple stream MIMO 802.11ac and 802.11n technology, as well as 802.11g and 802.11a.

For large deployments, some FortiAP models support a mesh mode of operation in which control and data backhaul traffic between APs and the controller are carried on a dedicated WiFi network. Users can roam seamlessly from one AP to another.

In dual-radio models, each radio can function as an AP or as a dedicated monitor. The monitoring function is also available during AP operation, subject to traffic levels.

The [Products](#) section of the Fortinet web site (www.fortinet.com) provides detailed information about the FortiAP models that are currently available.

Automatic Radio Resource Provisioning

To prevent interference between APs, the FortiOS WiFi Controller includes the Distributed Automatic Radio Resource Provisioning (DARRP) feature. Through DARRP, each FortiAP unit autonomously and periodically determines the channel that is best suited for wireless communications. FortiAP units to select their channel so that they do not interfere with each other in large-scale deployments where multiple access points have overlapping radio ranges.

To enable ARRP - GUI

1. Go to **WiFi Controller > FortiAP Profiles** and edit the profile for your device.
2. In the Radio sections (Radio 1, Radio 2, etc.), enable **Radio Resource Provision**.
3. Click **OK**.

To enable ARRP - CLI

In this example, ARRP is enabled for both radios in the FAP321C-default profile:

```
config wireless-controller wtp-profile
  edit FAP321C-default
    config radio-1
      set darrp enable
    end
    config radio-2
      set darrp enable
    end
  end
end
```

Setting ARP timing

By default, ARP optimization occurs at a fixed interval of 1800 seconds (30 minutes). You can change this interval in the CLI. For example, to change the interval to 3600 seconds enter:

```
config wireless-controller timers
  set darrp-optimize 3600
end
```

Optionally, you can schedule optimization for fixed times. This enables you to confine ARP activity to a low-traffic period. Setting `darrp-optimize` to 0, makes `darrp-day` and `darrp-time` available. For example, here's how to set DARRP optimization for 3:00am every day:

```
config wireless-controller timers
  set darrp-optimize 0
  set darrp-day sunday monday tuesday wednesday thursday friday saturday
  set darrp-time 03:00
end
```

Both `darrp-day` and `darrp-time` can accept multiple entries.

Captive portals

A captive portal is a convenient way to authenticate web users on wired or WiFi networks.

This section describes:

- [Introduction to captive portals](#)
- [Configuring a captive portal](#)
- [Customizing captive portal pages](#)
- [Configuration example - captive portal WiFi access control](#)

Introduction to captive portals

You can authenticate your users on a web page that requests the user's name and password. Until the user authenticates successfully, the authentication page is returned in response to any HTTP request. This is called a captive portal.

After successful authentication, the user accesses the requested URL and can access other web resources, as permitted by security policies. Optionally, the captive portal itself can allow web access to only the members of specified user group.

The captive portal can be hosted on the FortiGate unit or on an external authentication server. You can configure captive portal authentication on any network interface, including WiFi and VLAN interfaces.

When a captive portal is configured on a WiFi interface, the access point initially appears open. The wireless client can connect to the access point with no security credentials, but sees only the captive portal authentication page.

WiFi captive portal types:

- **Authentication** — until the user enters valid credentials, no communication beyond the AP is permitted.
- **Disclaimer + Authentication** — immediately after successful authentication, the portal presents the disclaimer page—an acceptable use policy or other legal statement—to which the user must agree before proceeding.
- **Disclaimer Only** — the portal presents the disclaimer page—an acceptable use policy or other legal statement—to which the user must agree before proceeding. The authentication page is not presented.
- **Email Collection** — the portal presents a page requesting the user's email address, for the purpose of contacting the person in future. This is often used by businesses who provide free WiFi access to their customers. The authentication page is not presented.
- **MAC Bypass** — when clients are authenticated against their bridged SSID and their MAC addresses are known, they are redirected to the external captive portal.

Configuring a captive portal

Captive portals are configured on network interfaces. A WiFi interface does not exist until the WiFi SSID is created. You can configure a WiFi captive portal at the time that you create the SSID. Afterwards, the captive portal settings will also be available by editing the WiFi network interface in **System > Network > Interfaces**. On a physical (wired) network interface, you edit the interface configuration in **System > Network > Interfaces** and set **Security Mode** to **Captive Portal**.

To configure a WiFi captive portal - web-based manager:

1. Go to **WiFi & Switch Controller > SSID** and create your SSID.
If the SSID already exists, you can edit the SSID or you can edit the WiFi interface in **Network > Interfaces**.
2. Under **WiFi Settings**, for **Security Mode**, select **Captive Portal**.

WiFi Settings

SSID	<input type="text" value="fortinet"/>
Security Mode	<input type="text" value="Captive Portal"/>
Client Limit	<input type="checkbox"/>
Portal Type	<input checked="" type="radio"/> Authentication <input type="radio"/> Disclaimer + Authentication <input type="radio"/> Disclaimer Only <input type="radio"/> Email Collection
Authentication Portal	<input type="text" value="Local"/> <input checked="" type="text" value="External"/>
	<input type="text" value="example.com/captive/"/>
User Groups	<input type="text" value="+"/> +
Exempt Sources	<input type="text" value="+"/> +
Exempt Destinations/Services	<input type="text" value="+"/> +
Redirect after Captive Portal	<input checked="" type="radio"/> Original Request <input type="radio"/> Specific URL

3. Enter the following:

Portal Type	The portal can provide authentication and/or disclaimer, or perform user email address collection. See Introduction to captive portals on page 1054 .
Authentication Portal	Local - portal hosted on the FortiGate unit. Remote - enter FQDN or IP address of external portal.
User Groups	Select permitted user groups.
Exempt Sources	Select exempt lists whose members will not be subject to captive portal authentication.
Exempt Destinations/Services	
Redirect after Captive Portal	Select whether to have authenticated users navigate to their originally requested URL or be redirected to another/specific URL.

4. Select **OK**.

To configure an SSID with external-web enabled - CLI:

```
config wireless-controller vap
  edit "web-ext"
    set vdom "root"
    set ssid "web-ext"
    set security captive-portal
    set selected-usergroups "qnap"
    set security-exempt-list "wifi"
    set security-redirect-url " http://www.fortinet.com"
    set intra-vap-privacy enable
```

```
    set local-switching disable
    set external-web "192.168.234.51/portal.php"
  next
end
```

Note that the `external-web` entry is the URL of the external authentication web server. When this entry is not set, the FortiGate will use the local web server hosting the local login/splash page.

The external web URL is not explicitly set with HTTP/HTTPS - FortiGate uses the `auth-secure-http` entry under `config user` setting.

Exemption from the captive portal

A captive portal requires all users on the interface to authenticate. But some devices are not able to authenticate. You can create an exemption list of these devices. For example, a printer might need to access the Internet for firmware upgrades. Using the CLI, you can create an exemption list to exempt all printers from authentication.

```
config user security-exempt-list
  edit r_exempt
    config rule
      edit <id>
        set devices printer
      end
    end
  end
```

Furthermore, a walled garden firewall policy can be created:

```
config firewall policy
  edit <id>
    set captive-portal-exempt enable
    ...
  next
end
```

MAC Bypass for captive portal

It is possible to provide a MAC address bypass for authenticated clients. When clients are authenticated with bridged SSID and their MAC addresses are known, they are redirected to the External Captive Portal.

A new portal type has been added, under `config wireless-controller vap`, to provide successful MAC authentication Captive Portal functionality.

Syntax

```
config wireless-controller vap
  edit {name}
    set portal-type {cmcc-macauth}
  next
end
```

MAC-auth-bypass for the captive-portal SSID

Captive-portal SSID supports MAC-auth-bypass. If a client's MAC can be authenticated from local-user or RADIUS, then the client can bypass firewall authentication directly.

```
config wireless-controller vap
  edit <name>
    set security captive-portal
    set MAC-auth-bypass {enable | disable}
```

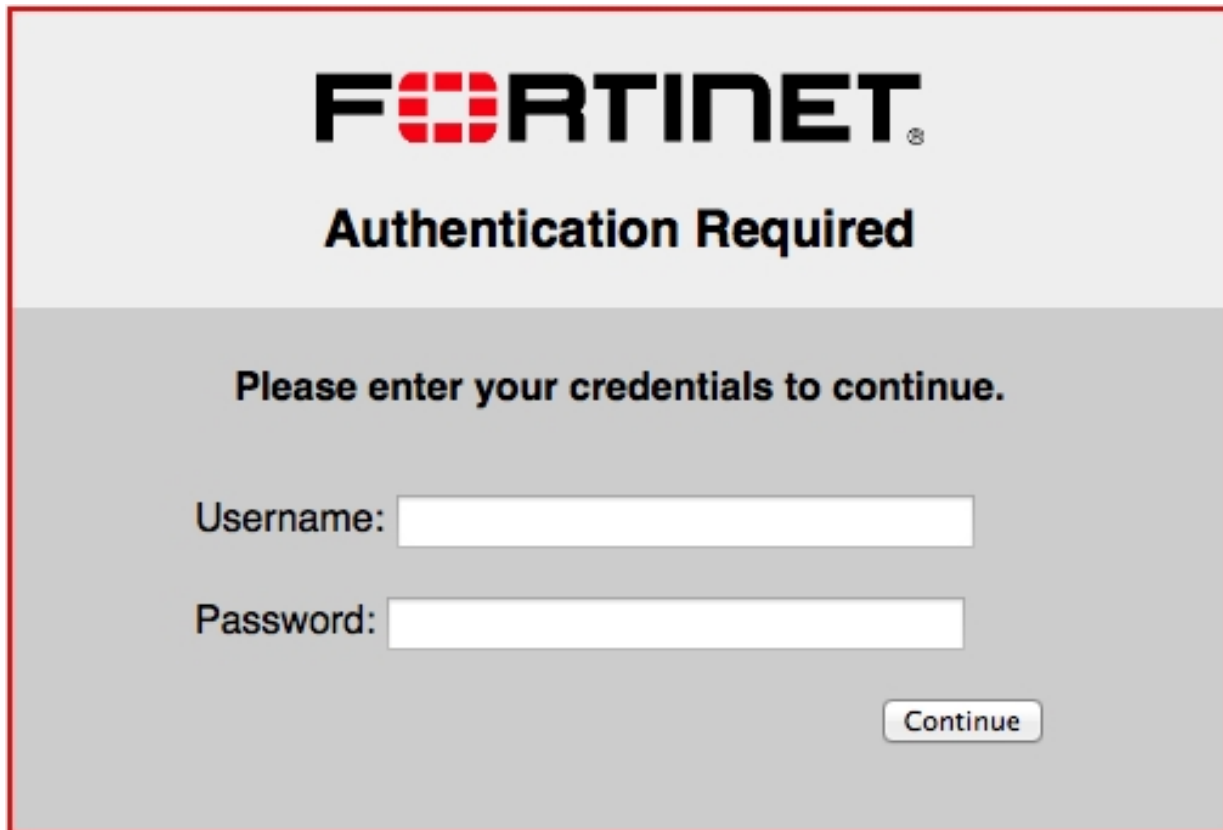

```
next
end
```

Customizing captive portal pages

These pages are defined in replacement messages. Defaults are provided. In the web-based manager, you can modify the default messages in the SSID configuration by selecting **Customize Portal Messages**. Each SSID can have its own unique portal content.

The captive portal contains the following default web pages:

- **Login page**—requests user credentials

The image shows a captive portal login page for Fortinet. At the top, the Fortinet logo is displayed in black and red. Below the logo, the text "Authentication Required" is centered in a bold, black font. Underneath this, a message "Please enter your credentials to continue." is also centered. There are two input fields: "Username:" followed by a white text box, and "Password:" followed by a white text box. At the bottom right of the form, there is a button labeled "Continue". The entire form is enclosed in a red border.

Typical modifications for this page would be to change the logo and modify some of the text.

You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters.

There is an exception to this rule. The line "Please enter your credentials to continue" is provided by the `%%QUESTION%%` tag. You can replace this tag with text of your choice. Except for this item, you should not remove any tags because they may carry information that the FortiGate unit needs.

- **Login failed page**—reports that the entered credentials were incorrect and enables the user to try again.

The image shows a captive portal page for Fortinet. At the top, the Fortinet logo is displayed in black and red. Below the logo, the text "Authentication Failed" is centered in a bold, black font. Underneath this, a message reads "Firewall Authentication failed. Please try again." in a bold, black font. Below the message, there are two input fields: "Username:" followed by a white text box, and "Password:" followed by a white text box. At the bottom right of the form, there is a button labeled "Continue". The entire form is enclosed in a red border.

The Login failed page is similar to the Login page. It even contains the same login form. You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters.

There is an exception to this rule. The line "Firewall authentication failed. Please try again." is provided by the %%FAILED_MESSAGE%% tag. You can replace this tag with text of your choice. Except for this item, you should not remove any tags because they may carry information that the FortiGate unit needs.

- **Disclaimer page**—is a statement of the legal responsibilities of the user and the host organization to which the user must agree before proceeding. (WiFi or SSL VPN only)

Terms and Disclaimer Agreement

You are about to access Internet content that is not under the control of the network access provider. The network access provider is therefore not responsible for any of these sites, their content or their privacy policies. The network access provider and its staff do not endorse nor make any representations about these sites, or any information, software or other products or materials found there, or any results that may be obtained from using them. If you decide to access any Internet content, you do this entirely at your own risk and you are responsible for ensuring that any accessed material does not infringe the laws governing, but not exhaustively covering, copyright, trademarks, pornography, or any other material which is slanderous, defamatory or might cause offence in any other way.

Do you agree to the above terms?

Yes, I agree

No, I decline

- **Declined disclaimer page**—is displayed if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

Changing images in portal messages

You can replace the default Fortinet logo with your organization's logo. First, import the logo file into the FortiGate unit and then modify the Login page code to reference your file.

To import a logo file:

1. Go to **System > Replacement Messages** and select **Manage Images**.
2. Select **Create New**.
3. Enter a **Name** for the logo and select the appropriate **Content Type**.
The file must not exceed 24 Kilo bytes.
4. Select **Browse**, find your logo file and then select **Open**.
5. Select **OK**.

To specify the new logo in the replacement message:

1. Go to **Network > Interfaces** and edit the interface.
The **Security Mode** must be **Captive Portal**.
2. Select the portal message to edit.
 - In SSL VPN or WiFi interfaces, in **Customize Portal Messages** click the link to the portal messages that you want to edit.
 - In other interfaces, make sure that **Customize Portal Messages** is selected, select the adjacent **Edit** icon, then select the message that you want to edit.
3. In the HTML message text, find the %%IMAGE tag.
By default it specifies the Fortinet logo: %%IMAGE:logo_fw_auth%%
4. Change the image name to the one you provided for your logo.
The tag should now read, for example, %%IMAGE:mylogo%%
5. Select **Save**.
6. Select **OK**.

Modifying text in portal messages

Generally, you can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters. You should not remove any tags because they may carry information that the FortiGate unit needs. See the preceding section for any exceptions to this rule for particular pages.

To modify portal page text

1. Go to **System > Network > Interfaces** and edit the interface.
The SSID **Security Mode** must be **Captive Portal**.
2. Select the portal message to edit.
 - In SSL VPN or WiFi interfaces, in **Customize Portal Messages** click the link to the portal messages that you want to edit.
 - In other interfaces, make sure that **Customize Portal Messages** is selected, select the adjacent **Edit** icon, then select the message that you want to edit.
3. Edit the HTML message text, then select **Save**.
4. Select **OK**.

Configuring disclaimer page for ethernet interface captive portals

While you can customize a disclaimer page for captive portals that connect via WiFi, the same can be done for wired connections. However, this can only be configured on the CLI Console, and only without configuring user groups.

When configuring a captive portal through the CLI, you may set `security-groups` to a specific user group. The result of this configuration will show an authentication form to users who wish to log in to the captive portal—**not** a disclaimer page. If you do not set any `security-groups` in your configuration, an "Allow all" status will be in effect, and the disclaimer page will be displayed for users.

The example CLI configuration below shows setting up a captive portal interface without setting security-groups, resulting in a disclaimer page for users:

```
config system interface
  edit "port1"
    set vdom "root"
    set ip 172.16.101.1 255.255.255.0
    set allowaccess ping https ssh snmp http
    set type physical
    set explicit-web-proxy enable
    set alias "LAN"
    set security-mode captive-portal
    set snmp-index 1
  next
end
```

Roaming support

Client devices can maintain captive portal authentication as they roam across different APs. By maintaining a consistent authentication, uninterrupted access to latency sensitive applications such as VoIP is ensured.

The Cloud will push a random per-AP Network encryption key to the AP. The key is 32 bytes in length, and is used in captive portal fast roaming. All APs of an AP Network will use the same encryption key. This key is randomly generated, and will be updated daily.

Session timeout interval for captive portal

The following syntax can be set to configure a session timeout interval in seconds for Captive Portal users. Set the range between 0 - 864000 (or no timeout to ten days). The default is set to 0.

This command is only available when **local-standalone** is set to **enable**, **security** is set to **captive-portal**, and then **portal-type** is set to either **cmcc** or **cmcc-macauth**.

Syntax

```
config wireless-controller vap
  edit <name>
    ...
    set captive-portal-session-timeout-interval <seconds>
  next
end
```

Configuration example - captive portal WiFi access control

In this scenario, you will configure the FortiGate for captive portal access so users can log on to your WiFi network.

You will create a user account (*rgreen*), add it to a user group (*employees*), create a captive portal SSID (*example-staff*), and configure a FortiAP unit. When the user attempts to browse the Internet, they will be redirected to the captive portal login page and asked to enter their username and password.

1. Enabling HTTPS authentication

Go to **User & Device > Authentication Settings**.

Under **Protocol Support**, enable **Redirect HTTP Challenge to a Secure Channel (HTTPS)**. This will make sure that user credentials are communicated securely through the captive portal.

2. Creating the user

Go to **User & Device > User Definition** and create a Local user (*rgreen*).

Create additional users if needed, and assign any authentication methods.

3. Creating the user group

Go to **User & Device > User Groups** and create a user group (*employees*).

Add **rgreen** to the group.

4. Creating the SSID

Go to **WiFi & Switch Controller > SSID** and configure the wireless network.
Some FortiGate models may show the GUI path as **WiFi & Switch Controller**.

Enter an **Interface Name** (*example-wifi*) and **IP/Network Mask**.

An address range under **DHCP Server** will be automatically configured.

Under **WiFi Settings**, enter an **SSID** name (*example-staff*), set **Security Mode** to **Captive Portal**, and add the **employees** user group.

5. Creating the security policy

Go to **Policy & Objects > Addresses** and create a new address for the SSID (*example-wifi-net*).

Set **Subnet/IP Range** to the same range set on the DHCP server in the previous step.

Set **Interface** to the SSID interface.

Go to **Policy & Objects > IPv4 Policy** and create a new policy for WiFi users to connect to the Internet.

Add both the **example-wifi-net** address and **employees** user group to **Source**.

6. Connecting and authorizing the FortiAP

Go to **Network > Interfaces** and edit an available interface.

Under **Address**, set **Addressing mode** to **Dedicated to Extension Device** and assign it an IP address.

Connect the FortiAP unit to the configured interface, then go to **WiFi & Switch Controller > Managed FortiAPs**.

The FortiAP is listed, but its **State** shows a greyed-out question mark — this is because it is waiting for authorization.

Highlight the FortiAP and select **Authorize**.

The question mark is now replaced by a red down-arrow — this is because it is authorized, but still offline.

Go to **WiFi & Switch Controller > FortiAP Profiles** and edit the profile.

For each radio, enable **Radio Resource Provision** and select your SSID.

Go back to **WiFi & Switch Controller > Managed FortiAPs** to verify that the FortiAP unit is online.

7. Results

When a user attempts to connect to the wireless network, they will be redirected to the captive portal login screen.

Members of the **employees** group must enter their **Username** and **Password**. The user will then be redirected to the URL originally requested.

On the FortiGate, go to **Monitor > WiFi Client Monitor** to verify that the user is authenticated.

Configuring a WiFi LAN

When working with a FortiGate WiFi controller, you can configure your wireless network before you install any access points. If you are working with a standalone FortiWiFi unit, the access point hardware is already present but the configuration is quite similar. Both are covered in this section.

On FortiGate model 30D, web-based manager configuration of the WiFi controller is disabled by default. To enable it, enter the following CLI commands:

```
config system global
    set gui-wireless-controller enable
end
```

The WiFi Controller and Switch Controller are enabled through the Feature Store (under **System > Feature Select**). However, they are separately enabled and configured to display in the GUI via the CLI.

To enable both WiFi and Switch controllers, enter the following:

```
config system global
    set wireless-controller enable
    set switch-controller enable
end
```

To enable the GUI display for both controllers, have also been separated:

```
config system settings
    set gui-wireless-controller enable
    set gui-switch-controller enable
end
```

If you want to connect and authorize external APs, such as FortiAP units, see the next chapter, [Access point deployment](#).

Overview of WiFi controller configuration

The FortiGate WiFi controller configuration is composed of three types of object, the SSID, the AP Profile and the physical Access Point.

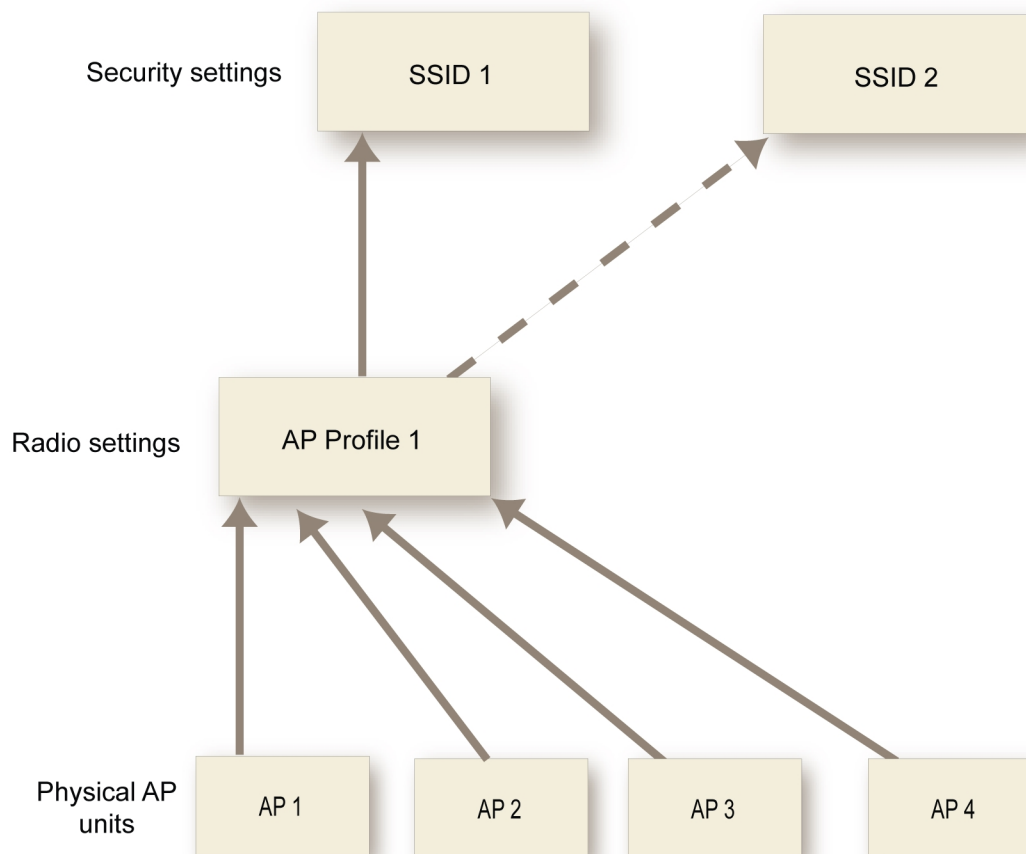

- An **SSID** defines a virtual wireless network interface, including security settings. One SSID is sufficient for a wireless network, regardless how many physical access points are provided. You might, however, want to create multiple SSIDs to provide different services or privileges to different groups of users. Each SSID has separate firewall policies and authentication. Each radio in an access point can support up to 8 SSIDs.

A more common use of the term SSID is for the identifier that clients must use to connect to the wireless network. Each SSID (wireless interface) that you configure will have an SSID field for this identifier. In Managed Access

Point configurations you choose wireless networks by SSID values. In firewall policies you choose wireless interfaces by their SSID name.

- An **AP Profile** defines the radio settings, such as band (802.11g for example) and channel selection. The AP Profile names the SSIDs to which it applies. Managed APs can use automatic profile settings or you can create AP profiles.
- **Managed Access Points** represent local wireless APs on FortiWiFi units and FortiAP units that the FortiGate unit has discovered. There is one managed access point definition for each AP device. An access point definition can use automatic AP profile settings or select a FortiAP Profile. When automatic profile settings are used, the managed AP definition also selects the SSIDs to be carried on the AP.

Conceptual view of FortiGate WiFi controller configuration

About SSIDs on FortiWiFi units

FortiWiFi units have a default SSID (wireless interface) named **wlan**. You can modify or delete this SSID as needed. As with external APs, the built-in wireless AP can be configured to carry any SSID.

The AP settings for the built-in wireless access point are located at **WiFi Controller > Local WiFi Radio**. The available operational settings are the same as those for external access points which are configured at **WiFi Controller > Managed FortiAPs**.

Process to create a wireless network

To set up your wireless network, you will need to perform the following steps:

- Make sure the FortiGate wireless controller is configured for your geographic location. This ensures that the available radio channels and radio power are in compliance with the regulations in your region.
- Optionally, if you don't want to use automatic AP profile settings, configure a FortiAP profile, specifying the radio settings and the SSIDs to which they apply.
- Configure one or more SSIDs for your wireless network. The SSID configuration includes DHCP and DNS settings.
- Configure the user group and users for authentication on the WLAN.
- Configure the firewall policy for the WLAN.
- Optionally, customize the captive portal.
- Configure access points.

Configuration of the built-in AP on FortiWiFi units is described in this chapter. Connection and configuration of FortiAP units is described in the next chapter, see [Access point deployment on page 1089](#).

Setting your geographic location

The maximum allowed transmitter power and permitted radio channels for WiFi networks depend on the region in which the network is located. By default, the WiFi controller is configured for the United States. If you are located in any other region, you need to set your location before you begin configuring wireless networks.

To change the location setting - CLI

To change the country to France, for example, enter

```
config wireless-controller setting
  set country FR
end
```

To see the list of country codes, enter a question mark ('?') instead of a country code.

Before changing the country setting, you must remove all FortiAP Profiles. To do this, go to **WiFi & Switch Controller > FortiAP Profiles**.

View all country and regcodes/regulatory domains

The following CLI command can be entered to view a list of the country and regcodes/regulatory Domains supported by Fortinet:

```
cw_diag -c all-countries
```

Below is a table showing a sample of the list displayed by entering this command:

Country-code	Region-code	Domain	ISO-name	Name
0	A	FCC3 & FCCA	NA	NO_COUNTRY_SET
8	W	NULL1 & WORLD	AL	ALBANIA
12	W	NULL1 & WORLD	DZ	ALGERIA

Country-code	Region-code	Domain	ISO-name	Name
16	A	FCC3 & FCCA	AS	AMERICAN SAMOA
...

Creating a FortiAP profile

A FortiAP profile defines radio settings for a particular platform (FortiAP model). The profile also selects which SSIDs (virtual APs) the APs will carry. FortiAP units contain two radio transceivers, making it possible, for example, to provide both 2.4GHz 802.11b/g/n and 5GHz 802.11a/n service from the same access point. The radios can also be used for monitoring, used for the Rogue AP detection feature.

You can modify existing FortiAP profiles or create new ones of your own.

On FortiGate model 30D, web-based manager configuration of FortiAP Profiles is disabled by default. To enable AP profiles, enter the following CLI commands:

```
config system settings
    set gui-ap-profile enable
end
```

To configure a FortiAP profile - web-based manager

1. Go to **WiFi & Switch Controller > FortiAP Profiles** and select **Create New**.
2. Enter a **Name** for the FortiAP Profile.
3. In **Platform**, select the FortiWiFi or FortiAP model to which this profile applies.
4. If split tunneling is used, in **Split Tunneling Subnets**, enter a comma-separated list all of the destination IP address ranges that should **not** be routed through the the FortiGate WiFi controller.
5. For each radio, enter:

Mode	Select the type of mode. Disable – radio disabled Access Point – the platform is an access point Dedicated Monitor – the platform is a dedicated monitor. See Wireless network monitoring on page 1145 .
WIDS Profile	Optionally, select a Wireless Intrusion Detection (WIDS) profile. See Protecting the WiFi network on page 1140 .
Radio Resource Provision	Select to enable the radio resource provision feature. This feature measures utilization and interference on the available channels and selects the clearest channel at each access point. The measurement can be repeated periodically to respond to changing conditions.
Client Load Balancing	Select Frequency Handoff or AP Handoff as needed. See Access point deployment on page 1089 .

Band	<p>Select the wireless protocols that you want to support. The available choices depend on the radio's capabilities. Where multiple protocols are supported, the letter suffixes are combined: "802.11g/b" means 802.11g and 802.11b.</p> <p>Note that on two-radio units such as the FortiAP-221C it is not possible to put both radios on the same band.</p>
Channel Width	Select channel width for 802.11ac or 802.11n on 5GHz.
Short Guard Interval	Select to enable the short guard interval for 802.11ac or 802.11n on 5GHz.
Channels	Select the channel or channels to include. The available channels depend on which IEEE wireless protocol you selected in Band . By default, all available channels are enabled.
TX Power Control	Enable automatic or manual adjustment of transmit power, specifying either minimum and maximum power levels in dBm or as a percentage.
TX Power	<p>When TX Power Control is set to Auto, the TX Power is set by default to a range of 10-17 dBm. Set the range between 1-20 for both the lower and upper limits.</p> <p>When TX Power Control is set to Manual, the TX Power is set by default to 100% of the maximum power permitted in your region. To change the level, drag the slider.</p>
SSIDs	<p>Select between Auto or Manual. Selecting Auto eliminates the need to re-edit the profile when new SSIDs are created. However, you can still select SSIDs individually using Manual.</p> <p>Note that automatic assignment of SSIDs (Auto) is not available for FortiAPs in Local Bridge mode. The option is hidden on both the Managed FortiAP settings and the FortiAP Profile assigned to that AP.</p>

Radio 1 settings are the same as Radio 2 settings except for the options for **Channel**.

Radio 2 settings are available only for FortiAP models with dual radios.

6. Select **OK**.

To configure a FortiAP profile - CLI

This example configures a FortiAP-220B to carry all SSIDs on Radio 1 but only SSID example_wlan on Radio 2.

```
config wireless-controller wtp-profile
  edit guest_prof
    config platform
      set type 220B
    end
    config radio-1
      set mode ap
      set band 802.11g
      set vap-all enable
    end
```

```

config radio-2
    set mode ap
    set band 802.11g
    set vaps example_wlan
end
end

```

Defining a wireless network interface (SSID)

You begin configuring your wireless network by defining one or more SSIDs to which your users will connect. When you create an SSID, a virtual network interface is also created with the **Name** you specified in the SSID configuration. You can configure the settings of an existing SSID in either **WiFi & Switch Controller > SSID** or **System > Network > Interfaces**.

If a software switch interface contains an SSID (but only one), the WiFi SSID settings are available in the switch interface settings.

To create a new SSID

1. Go to **WiFi & Switch Controller > SSID** and select **Create New > SSID**.
2. Fill in the SSID fields as described below.

To configure the settings of an existing SSID

1. Either
 - Go to **WiFi & Switch Controller > SSID**.
 or
 - Go to **Network > Interfaces**.
WiFi interfaces list the SSID beside the interface **Name**.
2. Edit a WiFi interface, modifying the SSID fields as needed.

SSID fields

Interface Name	Enter a name for the SSID interface.
Type	WiFi SSID.
Traffic Mode	<p>Tunnel to Wireless Controller — Data for WLAN passes through WiFi Controller. This is the default.</p> <p>Local bridge with FortiAP's Interface — FortiAP unit Ethernet and WiFi interfaces are bridged.</p> <p>Mesh Downlink — Radio receives data for WLAN from mesh backhaul SSID.</p>
IP/Network Mask	Enter the IP address and netmask for the SSID.

IPv6 Address	Enter the IPv6 address. This is available only when IPv6 has been enabled on the unit.
Administrative Access	Select which types of administrative access are permitted on this SSID.
IPv6 Administrative Access	If you have IPv6 addresses, select the permitted IPv6 administrative access types for this SSID.
DHCP Server	<p>To assign IP addresses to clients, enable DHCP server. You can define IP address ranges for a DHCP server on the FortiGate unit or relay DHCP requests to an external server.</p> <p>If the unit is in transparent mode, the DHCP server settings will be unavailable.</p> <p>For more information, see Configuring DHCP for WiFi clients on page 1073.</p>
Device Detection	Detect connected device type. Enabled by default.
Active Scanning	Enabled by default.
WiFi Settings	
SSID	Enter the SSID. By default, this field contains <code>fortinet</code> .
Security Mode	<p>Select the security mode for the wireless interface. Wireless users must use the same security mode to be able to connect to this wireless interface. Additional security mode options are available in the CLI. For more information, see Configuring security on page 1074.</p> <p>Captive Portal – authenticates users through a customizable web page.</p> <p>WPA2-Personal – WPA2 is WiFi Protected Access version 2. There is one pre-shared key (password) that all users use.</p> <p>WPA2-Personal with Captive Portal – The user will need to know the pre-shared key and will also be authenticated through the custom portal.</p> <p>WPA2-Enterprise – similar to WPA2-Personal, but is best used for enterprise networks. Each user is separately authenticated by user name and password.</p>
Pre-shared Key	Available only when Security Mode is WPA2-Personal . Enter the encryption key that the clients must use.

Authentication	Available only when Security Mode is WPA2-Enterprise . Select one of the following: RADIUS Server — Select the RADIUS server that will authenticate the clients. Local – Select the user group(s) that can authenticate.
Portal Type	Available only when Security Mode is Captive Portal . Choose the captive portal type. Authentication is available with or without a usage policy disclaimer notice.
Authentication Portal	Local - portal hosted on the FortiGate unit External - enter FQDN or IP address of external portal
User Groups	Select permitted user groups for captive portal authentication.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Click the listed portal pages to edit them.
Redirect after Captive Portal	Optionally, select Specific URL and enter a URL for user redirection after captive portal authentication. By default, users are redirected to the URL that they originally requested.
Allow New WiFi Client Connections When Controller Is Down	This option is available for local bridge SSIDs with WPA-Personal security. See Combining WiFi and wired networks with a software switch on page 1122 .
Broadcast SSID	Optionally, disable broadcast of SSID. By default, the SSID is broadcast. For more information, see Introduction to wireless networking on page 1048 .
Schedule	Select when the SSID is enabled. You can choose any schedule defined in Policy & Objects > Objects > Schedules .
Block Intra-SSID Traffic	Select to enable the unit to block intra-SSID traffic.
Maximum Clients	Select to limit the number of clients permitted to connect simultaneously. Enter the limit value.
Split Tunneling	Select to enable some subnets to remain local to the remote FortiAP. Traffic for these networks is not routed through the WiFi Controller. Specify split-tunnel networks in the FortiAP Profile. See Split tunneling on page 1128 .
Optional VLAN ID	Enter the ID of the VLAN this SSID belongs to. Enter 0 for non-VLAN operation.

Enable Explicit Web Proxy	Select to enable explicit web proxy for the SSID.
Listen for RADIUS Accounting Messages	Enable if you are using RADIUS-based single sign-on (SSO).
Secondary IP Address	Optionally, enable and define secondary IP addresses. Administrative access can be enabled on secondary interfaces.
Comments	Enter a description or comment for the SSID.

To configure a virtual access point (SSID) - CLI

The example below creates an access point with SSID “example” and WPA2-Personal security. The wireless interface is named example_wlan.

WiFi SSIDs include a schedule that determines when the WiFi network is available. The default schedule is Always. You can choose any schedule (but not schedule group) that is defined in **Policy & Objects > Objects > Schedules**.

```
config wireless-controller vap
  edit example_wlan
    set ssid "example"
    set broadcast-ssid enable
    set security wpa2-only-personal
    set passphrase "hardtoguess"
    set schedule always
    set vdom root
  end
config system interface
  edit example_wlan
    set ip 10.10.120.1 255.255.255.0
  end
```

Configuring DHCP for WiFi clients

Wireless clients need to have IP addresses. If you use RADIUS authentication, each user’s IP address can be stored in the Framed-IP-Address attribute. Otherwise, you need to configure a DHCP server on the WLAN interface to assign IP addresses to wireless clients.

To configure a DHCP server for WiFi clients - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and edit your SSID entry.
2. In **DHCP Server** select **Enable**.
3. In **Address Range**, select **Create New**.
4. In the **Starting IP** and **End IP** fields, enter the IP address range to assign.
By default an address range is created in the same subnet as the wireless interface IP address, but not including that address.
5. Set the **Netmask** to an appropriate value, such as 255.255.255.0.
6. Set the **Default Gateway** to **Same as Interface IP**.

7. Set the **DNS Server** to **Same as System DNS**.
8. If you want to restrict access to the wireless network by MAC address, see [Adding a MAC filter on page 1076](#).
9. Select **OK**.

To configure a DHCP server for WiFi clients - CLI

In this example, WiFi clients on the example_wlan interface are assigned addresses in the 10.10.120.2-9 range to connect with the WiFi access point on 10.10.120.1.

```
config system dhcp server
  edit 0
    set default-gateway 10.10.120.1
    set dns-service default
    set interface example_wlan
    set netmask 255.255.255.0
    config ip-range
      edit 1
        set end-ip 10.10.120.9
        set start-ip 10.10.120.2
      end
    end
  end
```

You cannot delete an SSID (wireless interface) that has DHCP enabled on it.

Configuring security

Using the web-based manager, you can configure captive portal security or WiFi Protected Access version 2 (WPA2) security modes WPA2-Personal and WPA2-Enterprise. Using the CLI, you can also choose WPA/WPA2 modes that support both WPA version 1 and WPA version 2.

WPA2 security with a pre-shared key for authentication is called WPA2-Personal. This can work well for one person or a small group of trusted people. But, as the number of users increases, it is difficult to distribute new keys securely and there is increased risk that the key could fall into the wrong hands.

A more secure form of WPA2 security is WPA2-Enterprise. Users each have their own authentication credentials, verified through an authentication server, usually RADIUS. FortiOS can also authenticate WPA2-Enterprise users through its built-in user group functionality. FortiGate user groups can include RADIUS servers and can select users by RADIUS user group. This makes possible Role-Based Access Control (RBAC).

By default, WPA2 security encrypts communication using Advanced Encryption Standard (AES). But some older wireless clients support only Temporal Key Integrity Protocol (TKIP). You can change the encryption to TKIP or negotiable TKIP-AES in the CLI. For example, to accommodate clients with either TKIP or AES, enter:

```
config wireless-controller vap
  edit example_wlan
    set security wpa-personal
    set passphrase "hardtoguess"
    set encrypt TKIP-AES
  end
```

Captive portal security connects users to an open web portal defined in replacement messages. To navigate to any location beyond the web portal, the user must pass FortiGate user authentication.

WPA-Personal security

WPA2-Personal security setup requires only the preshared key that you will provide to your clients.

To configure WPA2-Personal security - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and edit your SSID entry.
2. In **Security Mode**, select **WPA2 Personal**.
3. In **Pre-shared Key**, enter a key between 8 and 63 characters long.
4. Select **OK**.

To configure WPA2-Personal security - CLI

```
config wireless-controller vap
  edit example_wlan
    set security wpa2-personal
    set passphrase "hardtoguess"
  end
```

WPA-Enterprise security

If you will use FortiOS user groups for authentication, go to **User & Device > User > User Groups** and create those groups first. The groups should be Firewall groups.

If you will use a RADIUS server to authenticate wireless clients, you must first configure the FortiGate unit to access the RADIUS server.

To configure FortiGate unit access to the RADIUS server - web-based manager

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter a **Name** for the server.
3. In **Primary Server Name/IP**, enter the network name or IP address for the server.
4. In **Primary Server Secret**, enter the shared secret used to access the server.
5. Optionally, enter the information for a secondary or backup RADIUS server.
6. Select **OK**.

To configure the FortiGate unit to access the RADIUS server - CLI

```
config user radius
  edit exampleRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret aoewmntiasf
  end
```

RADIUS Change of Authorization (CoA) support

The CoA feature enables the FortiGate to receive a client disconnect message from the RADIUS server. This is used to disconnect clients when their time, credit or bandwidth had been used up. Enable this on the RADIUS server using the CLI:

```
config user radius
  edit <name>
```

```
set radius-coa enable
end
```

To configure WPA-Enterprise security - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and edit your SSID entry.
2. In **Security Mode**, select **WPA2 Enterprise**.
3. In **Authentication**, do one of the following:
 - If you will use a RADIUS server for authentication, select **RADIUS** Server and then select the RADIUS server.
 - If you will use a local user group for authentication, select **Local** and then select the user group(s) permitted to use the wireless network.
4. Select **OK**.

To configure WPA-Enterprise security - CLI

```
config wireless-controller vap
edit example_wlan
set security wpa2-enterprise
set auth radius
set radius-server exampleRADIUS
end
```

Captive portal security

Captive portal security provides an access point that initially appears open. The wireless client can connect to the AP with no security credentials. The AP responds to the client's first HTTP request with a web page requesting user name and password. Until the user enters valid credentials, no communication beyond the AP is permitted.

The captive portal can be hosted on the FortiGate unit, or externally. For details see

[Configuring WiFi captive portal security - FortiGate captive portal on page 1078](#)

[Configuring WiFi captive portal security - external server on page 1078](#)

For general information about captive portals, see the Captive Portal chapter of the Authentication Guide.

Adding a MAC filter

On each SSID, you can create a MAC address filter list to either permit or exclude a list of clients identified by their MAC addresses.

This is actually not as secure as it appears. Someone seeking unauthorized access to your network can obtain MAC addresses from wireless traffic and use them to impersonate legitimate users. A MAC filter list should only be used in conjunction with other security measures such as encryption.

To configure a MAC filter - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and edit your SSID entry.
2. In the **DHCP Server** section, expand **Advanced**.
3. In **MAC Reservation + Access Control**, double-click in the **Unknown MAC Addresses** line and select **Assign IP** or **Block**, as needed.
By default, unlisted MAC addresses are assigned an IP address automatically.
4. In **MAC Reservation + Access Control**, select **Create New**.

5. Enter a MAC address in the **MAC** field.
6. In **IP or Action**, select one of:
 - **Reserve IP** — enter the IP address that is always assigned to this MAC address.
 - **Assign IP** — an IP address is assigned to this MAC address automatically.
 - **Block** — This MAC address will not be assigned an IP address.
7. Repeat steps 4 through 6 for each additional MAC address that you want to add.
8. Select **OK**.

To configure a MAC filter - CLI

1. Enter

```
config system dhcp server
show
```
2. Find the entry where `interface` is your WiFi interface. Edit that entry and configure the MAC filter. In this example, the MAC address 11:11:11:11:11:11 will be excluded. Unlisted MAC addresses will be assigned an IP address automatically.

```
edit 3
config reserved-address
edit 1
set action block
set mac 11:11:11:11:11:11
end
set mac-acl-default-action assign
end
```

Limiting the number of clients

You might want to prevent overloading of your access point by limiting the number of clients who can associate with it at the same time. Limits can be applied per SSID, per AP, or per radio.

To limit the number of clients per SSID - GUI

1. Go to **WiFi & Switch Controller > SSID** and edit your SSID.
2. Turn on **Maximum Clients** and enter the maximum number of clients in **Limit Concurrent WiFi Clients**.

To limit the number of clients per AP - CLI

Edit the wtp-profile (FortiAP profile), like this:

```
config wireless-controller wtp-profile
edit "FAP221C-default"
set max-clients 30
end
```

To limit the number of clients per radio - CLI

Edit the wtp-profile (FortiAP profile), like this:

```
config wireless-controller wtp-profile
edit "FAP221C-default"
config radio-1
set max-clients 10
```

```

end
config radio-2
    set max-clients 30
end
end

```

Multicast enhancement

FortiOS can translate multicast traffic into unicast traffic to send to clients, maintaining its own multicast client through IGMP snooping. You can configure this in the CLI:

```

config wireless-controller vap
    edit example_wlan
        set multicast-enhance enable
        set me-disable-thresh 32
    end
end

```

If the number of clients on the SSID is larger than `me-disable-thresh`, multicast enhancement is disabled.

Configuring WiFi captive portal security - FortiGate captive portal

The built-in FortiGate captive portal is simpler than an external portal. It can even be customized if needed.

To configure a WiFi Captive Portal - web-based manager:

1. Go to **WiFi & Switch Controller > SSID** and create your SSID.
If the SSID already exists, you can edit the SSID or you can edit the WiFi interface in **Network > Interfaces**.
2. In **Security Mode**, select **Captive Portal**.
3. Enter

Portal Type	The portal can provide authentication and/or disclaimer, or perform user email address collection. See Defining a wireless network interface (SSID) on page 1070 .
Authentication Portal	Local
User Groups	Select permitted user groups or select Use Groups from Policies , which permits the groups specified in the security policy.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Click the link of the portal page that you want to modify. For more information see the Captive Portal chapter of the Authentication Guide.

4. Select **OK**.

Configuring WiFi captive portal security - external server

An external captive portal is a web page on a web server. The essential part of the web portal page is a script that gathers the user's logon credentials and sends back to the FortiGate a specifically-formatted POST message.

The portal page can also contain links to local information such as legal notices, terms of service and so on.

Without authenticating, the user cannot access any other information. This is sometimes called a “walled garden”.

On the captive portal page, the user submits credentials, which the script returns to the FortiGate at the URL **https://<FGT_IP>:1000/fgtauth** with data

magic=session_id&username=<username>&password=<password>.

(The magic value was provided in the initial FortiGate request to the web server.)

To ensure that credentials are communicated securely, enable the use of HTTPS for authentication:

```
config user setting
    set auth-secure-http enable
end
```

To configure use of an external WiFi Captive Portal - web-based manager:

1. Go to **WiFi & Switch Controller > SSID** and create your SSID.
If the SSID already exists, you can edit the SSID or you can edit the WiFi interface in **Network > Interfaces**.
2. In **Security Mode**, select **Captive Portal**.
3. Enter

Portal Type	The portal can provide authentication and/or disclaimer, or perform user email address collection.
Authentication Portal	External - enter the FQDN or IP address of the external portal. Typically, this is the URL of a script. Do not include the protocol (http:// or https://) part of the URL.
User Groups	Select permitted user groups or select Use Groups from Policies , which permits the groups specified in the security policy.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Redirect after Captive Portal	Original Request Specific URL - enter URL

4. Select **OK**.

Defining SSID groups

Optionally, you can define SSID groups. An SSID group has SSIDs as members and can be specified just like an SSID in a FortiAP Profile.

To create an SSID group - GUI

Go to **WiFi & Switch Controller > SSID** and select **Create New > SSID Group**. Give the group a **Name** and choose **Members** (SSIDs, but not SSID groups).

To create an SSID group - CLI:

```
config wireless-controller vap-group
```

```
edit vap-group-name
  set vaps "ssid1" "ssid2"
end
```

Dynamic user VLAN assignment

Clients connecting to the WiFi network can be assigned to a VLAN. You can do this with RADIUS attributes when the user authenticates or with VLAN pooling when the client associates with a particular FortiAP. You cannot use both of these methods at the same time.

VLAN assignment by RADIUS

You can assign each individual user to a VLAN based on information stored in the RADIUS authentication server. If the user's RADIUS record does not specify a VLAN ID, the user is assigned to the default VLAN for the SSID.

The RADIUS user attributes used for the VLAN ID assignment are:

IETF 64 (Tunnel Type)—Set this to VLAN.

IETF 65 (Tunnel Medium Type)—Set this to 802

IETF 81 (Tunnel Private Group ID)—Set this to the VLAN ID.

To configure dynamic VLAN assignment, you need to:

1. Configure access to the RADIUS server.
2. Create the SSID and enable dynamic VLAN assignment.
3. Create a FortiAP Profile and add the local bridge mode SSID to it.
4. Create the VLAN interfaces and their DHCP servers.
5. Create security policies to allow communication from the VLAN interfaces to the Internet.
6. Authorize the FortiAP unit and assign the FortiAP Profile to it.

To configure access to the RADIUS server

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter a **Name**, the name or IP address in **Primary Server IP/Name**, and the server secret in **Primary Server Secret**.
3. Select **OK**.

To create the dynamic VLAN SSID

1. Go to **WiFi & Switch Controller > SSID**, select **Create New > SSID** and enter:

Name	An identifier, such as dynamic_vlan_ssid.
Traffic Mode	Local bridge or Tunnel, as needed.
SSID	An identifier, such as DYNSSID.
Security Mode	WPA2 Enterprise
Authentication	RADIUS Server. Select the RADIUS server that you configured.

2. Select **OK**.
3. Enable dynamic VLAN in the CLI. Optionally, you can also assign a VLAN ID to set the default VLAN for users without a VLAN assignment.

```
config wireless-controller vap
  edit dynamic_vlan_ssid
    set dynamic-vlan enable
    set vlanid 10
  end
```

To create the FortiAP profile for the dynamic VLAN SSID

1. Go to **WiFi & Switch Controller > FortiAP Profiles**, select **Create New** and enter:

Name	A name for the profile, such as dyn_vlan_profile.
Platform	The FortiAP model you are using. If you use more than one model of FortiAP, you will need a FortiAP Profile for each model.
Radio 1 and Radio 2	
SSID	Select the SSID you created (example dynamic_vlan_ssid). Do not add other SSIDs.

2. Adjust other radio settings as needed.
3. Select **OK**.

To create the VLAN interfaces

1. Go to **Network > Interfaces** and select **Create New > Interface**.
2. Enter:

Name	A name for the VLAN interface, such as VLAN100.
Interface	The physical interface associated with the VLAN interface.
VLAN ID	The numeric VLAN ID, for example 100.
Addressing mode	Select Manual and enter the IP address / Network Mask for the virtual interface.
DHCP Server	Enable and then select Create New to create an address range.

3. Select **OK**.
4. Repeat the preceding steps to create other VLANs as needed.

Security policies determine which VLANs can communicate with which other interfaces. These are the simple Firewall Address policy without authentication. Users are assigned to the appropriate VLAN when they authenticate.

To connect and authorize the FortiAP unit

1. Connect the FortiAP unit to the FortiGate unit.
2. Go to **WiFi & Switch Controller > Managed FortiAPs**.

3. When the FortiAP unit is listed, double-click the entry to edit it.
4. In **FortiAP Profile**, select the FortiAP Profile that you created.
5. Select **Authorize**.
6. Select **OK**.

VLAN assignment by VLAN pool

In an SSID, you can define a VLAN pool. As clients associate to an AP, they are assigned to a VLAN. A VLAN pool can

- assign a specific VLAN based on the AP's FortiAP group, usually for network configuration reasons, or
- assign one of several available VLANs for network load balancing purposes (tunnel mode SSIDs only)

To assign a VLAN by FortiAP group - CLI

In this example, VLAN 101, 102, or 103 is assigned depending on the AP's FortiAP group.

```
config wireless-controller vap
  edit wlan
    set vlan-pooling wtp-group
    config vlan-pool
      edit 101
        set wtp-group wtpgrp1
      next
      edit 102
        set wtp-group wtpgrp2
      next
      edit 103
        set wtp-group wtpgrp3
      end
    end
  end
end
```

Load balancing

There are two VLAN pooling methods used for load balancing:

The choice of VLAN can be based on any one of the following criteria:

- **round-robin** - from the VLAN pool, choose the VLAN with the smallest number of clients
- **hash** - choose a VLAN from the VLAN pool based on a hash of the current number of SSID clients and the number of entries in the VLAN pool

If the VLAN pool contains no valid VLAN ID, the SSID's static VLAN ID setting is used.

To assign a VLAN by round-robin selection - CLI

In this example, VLAN 101, 102, or 103 is assigned using the round-robin method:

```
config wireless-controller vap
  edit wlan
    set vlan-pooling round-robin
    config vlan-pool
      edit 101
      next
      edit 102
```

```
        next
        edit 103
        end
    end
end
```

To assign a VLAN by hash-based selection - CLI

In this example, VLAN 101, 102, or 103 is assigned using the hash method:

```
config wireless-controller vap
edit wlan
set vlan-pooling hash
config vlan-pool
edit 101
next
edit 102
next
edit 103
end
end
end
```

Configuring user authentication

You can perform user authentication when the wireless client joins the wireless network and when the wireless user communicates with another network through a firewall policy. WEP and WPA-Personal security rely on legitimate users knowing the correct key or passphrase for the wireless network. The more users you have, the more likely it is that the key or passphrase will become known to unauthorized people. WPA-Enterprise and captive portal security provide separate credentials for each user. User accounts can be managed through FortiGate user groups or an external RADIUS authentication server.

WPA2 Enterprise authentication

Enterprise authentication can be based on the local FortiGate user database or on a remote RADIUS server. Local authentication is essentially the same for WiFi users as it is for wired users, except that authentication for WiFi users occurs when they associate their device with the AP. Therefore, enterprise authentication must be configured in the SSID. WiFi users can belong to user groups just the same as wired users and security policies will determine which network services they can access.

If your WiFi network uses WPA2 Enterprise authentication verified by a RADIUS server, you need to configure the FortiGate unit to connect to that RADIUS server.

Configuring connection to a RADIUS server - web-based manager

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter a **Name** for the server.
This name is used in FortiGate configurations. It is not the actual name of the server.
3. In **Primary Server Name/IP**, enter the network name or IP address for the server.
4. In **Primary Server Secret**, enter the shared secret used to access the server.
5. Optionally, enter the information for a secondary or backup RADIUS server.
6. Select **OK**.

To configure the FortiGate unit to access the RADIUS server - CLI

```
config user radius
  edit exampleRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret aoewmntiasf
  end
```

To implement WPA2 Enterprise security, you select this server in the SSID security settings. See [Configuring user authentication on page 1083](#).

To use the RADIUS server for authentication, you can create individual FortiGate user accounts that specify the authentication server instead of a password, and you then add those accounts to a user group. Or, you can add the authentication server to a FortiGate user group, making all accounts on that server members of the user group.

Creating a wireless user group

Most wireless networks require authenticated access. To enable creation of firewall policies specific to WiFi users, you should create at least one WiFi user group. You can add or remove users later. There are two types of user group to consider:

- A Firewall user group can contain user accounts stored on the FortiGate unit or external authentication servers such as RADIUS that contain and verify user credentials.
- A Fortinet single sign-on (FSSO) user group is used for integration with Windows Active Directory or Novell eDirectory. The group can contain Windows or Novell user groups who will be permitted access to the wireless LAN.

WiFi single sign-on (WSSO) authentication

WSSO is RADIUS-based authentication that passes the user's user group memberships to the FortiGate. For each user, the RADIUS server must provide user group information in the Fortinet-Group-Name attribute. This information is stored in the server's database. After the user authenticates, security policies provide access to network services based on user groups.

1. Configure the RADIUS server to return the Fortinet-Group-Name attribute for each user.
2. Configure the FortiGate to access the RADIUS server, as described in [WPA2 Enterprise authentication on page 1083](#).
3. Create firewall user groups on the FortiGate with the same names as the user groups listed in the RADIUS database. Leave the groups empty.
4. In the SSID choose WPA2-Enterprise authentication. In the **Authentication** field, select **RADIUS Server** and choose the RADIUS server that you configured.
5. Create security policies as needed, using user groups (**Source User(s)** field) to control access.

When a user authenticates by WSSO, the firewall monitor **Monitor > Firewall User Monitor**) shows the authentication method as WSSO.

Assigning WiFi users to VLANs dynamically

Some enterprise networks use Virtual LANs (VLANs) to separate traffic. In this environment, to extend network access to WiFi users might appear to require multiple SSIDs. But it is possible to automatically assign each user to their appropriate VLAN from a single SSID. To accomplish this requires RADIUS authentication that passes the appropriate VLAN ID to the FortiGate by RADIUS attributes. Each user's VLAN assignment is stored in the user database of the RADIUS server.

1. Configure the RADIUS server to return the following attributes for each user:
Tunnel-Type (value: VLAN)
Tunnel-Medium-Type (value: IEEE-802)
Tunnel_Private-Group-Id (value: the VLAN ID for the user's VLAN)
2. Configure the FortiGate to access the RADIUS server.
3. Configure the SSID with WPA2-Enterprise authentication. In the **Authentication** field, select **RADIUS Server** and choose the RADIUS server that you will use.
4. Create VLAN subinterfaces on the SSID interface, one for each VLAN. Set the VLAN ID of each as appropriate. You can do this on the **Network > Interfaces** page.
5. Enable Dynamic VLAN assignment for the SSID. For example, if the SSID interface is "office", enter:

```
config wireless-controller vap
  edit office
    set dynamic-vlan enable
  end
```
6. Create security policies for each VLAN. These policies have a WiFi VLAN subinterface as **Incoming Interface** and allow traffic to flow to whichever **Outgoing Interface** these VLAN users will be allowed to access.

MAC-based authentication

Wireless clients can also be supplementally authenticated by MAC address. A RADIUS server stores the allowed MAC address for each client and the wireless controller checks the MAC address independently of other authentication methods.

MAC-based authentication must be configured in the CLI. In the following example, MAC-based authentication is added to an existing access point "vap1" to use RADIUS server hq_radius (configured on the FortiGate):

```
config wireless-controller vap
  edit vap1
    set radius-mac-auth enable
    set radius-mac-auth-server hq_radius
  end
```

Authenticating guest WiFi users

The FortiOS Guest Management feature enables you to easily add guest accounts to your FortiGate unit. These accounts are authenticate guest WiFi users for temporary access to a WiFi network managed by a FortiGate unit. To implement guest access, you need to

1. Go to **User & Device > User Groups** and create one or more guest user groups.
2. Go to **User & Device > Guest Management** to create guest accounts. You can print the guest account credentials or send them to the user as an email or SMS message.
3. Go to **WiFi & Switch Controller > SSID** and configure your WiFi SSID to use captive portal authentication. Select the guest user group(s) that you created.

Guest users can log into the WiFi captive portal with their guest account credentials until the account expires. For more detailed information about creating guest accounts, see "Managing Guest Access" in the Authentication chapter of the FortiOS Handbook.

Configuring firewall policies for the SSID

For users on the WiFi LAN to communicate with other networks, firewall policies are required. This section describes creating a WiFi network to Internet policy.

Before you create firewall policies, you need to define any firewall addresses you will need.

To create a firewall address for WiFi users - web-based manager

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, enter the following information and select **OK**.

Name	Enter a name for the address, wifi_net for example.
Type	Select Subnet .
Subnet / IP Range	Enter the subnet address, 10.10.110.0/24 for example.
Interface	Select the interface where this address is used, e.g., example_wifi

To create a firewall address for WiFi users - CLI

```
config firewall address
  edit "wifi_net"
    set associated-interface "example_wifi"
    set subnet 10.10.110.0 255.255.255.0
  end
```

To create a firewall policy - web-based manager

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. In **Incoming Interface**, select the wireless interface.
3. In **Source Address**, select the address of your WiFi network, wifi_net for example.
4. In **Outgoing Interface**, select the Internet interface, for example, port1.
5. In **Destination Address**, select **All**.
6. In **Service**, select **ALL**, or select the particular services that you want to allow, and then select the right arrow button to move the service to the **Selected Services** list.
7. In **Schedule**, select **always**, unless you want to define a schedule for limited hours.
8. In **Action**, select **ACCEPT**.
9. Select **Enable NAT**.
10. Optionally, set up UTM features for wireless users.
11. Select **OK**.

To create a firewall policy - CLI

```
config firewall policy
  edit 0
    set srcintf "example_wifi"
    set dstintf "port1"
    set srcaddr "wifi_net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
  end
```

Configuring the built-in access point on a FortiWiFi unit

Both FortiGate and FortiWiFi units have the WiFi controller feature. If you configure a WiFi network on a FortiWiFi unit, you can also use the built-in wireless capabilities in your WiFi network as one of the access points.

If Virtual Domains are enabled, you must select the VDOM to which the built-in access point belongs. You do this in the CLI. For example:

```
config wireless-controller global
    set local-radio-vdom vdom1
end
```

To configure the FortiWiFi unit's built-in WiFi access point

1. Go to **WiFi Controller > Local WiFi Radio**.
2. Make sure that **Enable WiFi Radio** is selected.
3. In **SSID**, if you do not want this AP to carry all SSIDs, select **Select SSIDs** and then select the required SSIDs.
4. Optionally, adjust the **TX Power** slider.
If you have selected your location correctly (see [Configuring the built-in access point on a FortiWiFi unit on page 1087](#)), the 100% setting corresponds to the maximum power allowed in your region.
5. If you do not want the built-in WiFi radio to be used for rogue scanning, select **Do not participate in Rogue AP scanning**.
6. Select **OK**.

If you want to connect external APs, such as FortiAP units, see the next chapter, [Access point deployment](#).

Enforcing UTM policies on a local bridge SSID for managed smart APs

The `config wireless-controller utm-profile` command lets administrators configure UTM profiles in order to enforce UTM policies on a local bridge SSID when Smart AP's are managed by FortiGate.

As a result, these UTM profiles can also be assigned under `config wireless-controller vap`.

Please note that this is only supported in Bridge-mode.

In addition, a new diagnose command has been introduced to determine the status of the `cw_acd` daemon, which handles the communication between FortiGate and APs.

Note that the default `utm-profile` available (named `wifi-default`) has all applicable options within the command set to `wifi-default`.

Use "?" to view all available profiles to assign, for example, "`set ips-sensor ?`".

Syntax:

```
config wireless-controller utm-profile
    edit <name>
        set comment <comment>
        set utm-log {enable | disable}
        set ips-sensor <name>
        set application-list <name>
        set antivirus-profile <name>
        set webfilter-profile <name>
        set firewall-policy <id>
        set scan-botnet-connections {disable | block | monitor}
```

```
    next
end

config wireless-controller vap
    edit <name>
        set utm-profile <name>
    next
end
```

To debug the `cw_acd_helper` daemon, use the following diagnose command:

```
diagnose wireless-controller wlac_hlp
```

Access point deployment

This chapter describes how to configure access points for your wireless network.

Overview

FortiAP units discover WiFi controllers. The administrator of the WiFi controller authorizes the FortiAP units that the controller will manage.

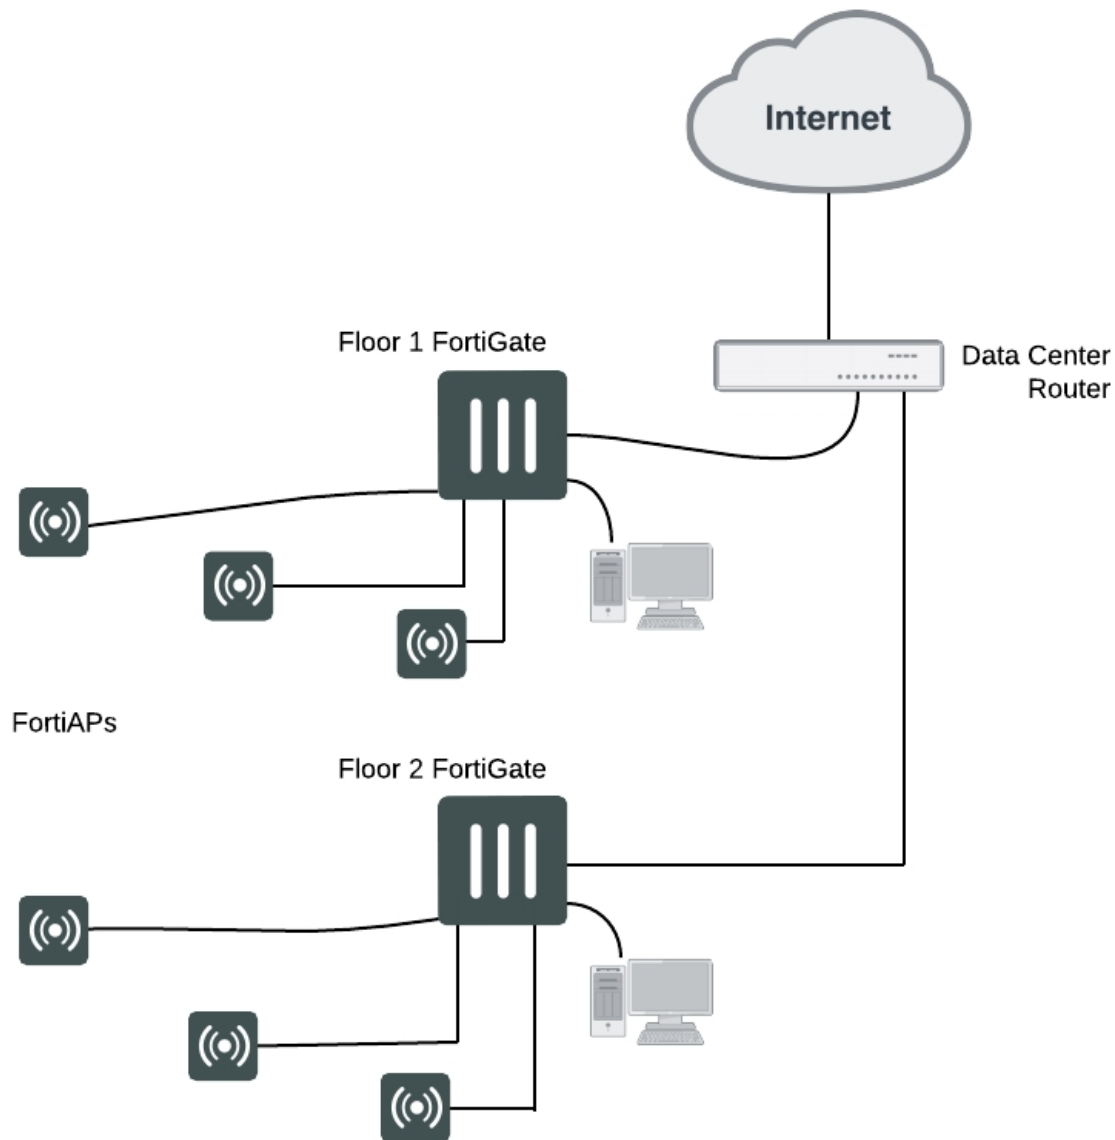

In most cases, FortiAP units can find WiFi controllers through the wired Ethernet without any special configuration. Review the following section, [Access point deployment on page 1089](#), to make sure that your method of connecting the FortiAP unit to the WiFi controller is valid. Then, you are ready to follow the procedures in [Access point deployment on page 1089](#).

If your FortiAP units are unable to find the WiFi controller, refer to [Access point deployment on page 1089](#) for detailed information about the FortiAP unit's controller discovery methods and how you can configure them.

Network topology for managed APs

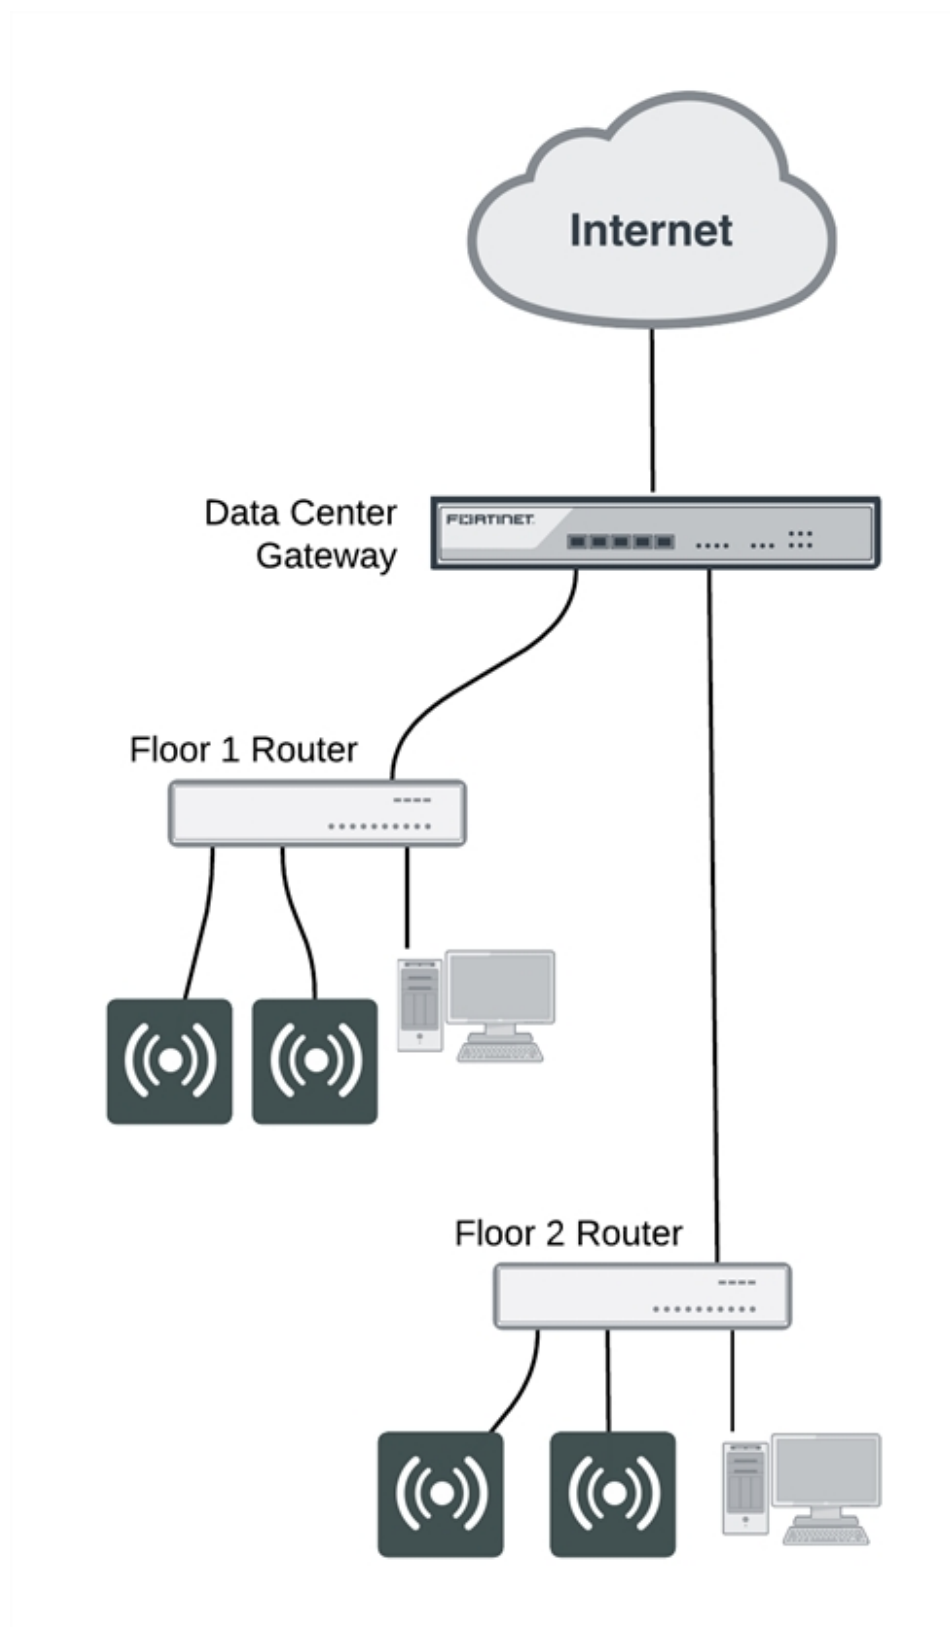

The FortiAP unit can be connected to the FortiGate unit in any of the following ways:

Direct connection: The FortiAP unit is directly connected to the FortiGate unit with no switches between them. This configuration is common for locations where the number of FortiAP's matches up with the number of 'internal' ports available on the FortiGate. In this configuration the FortiAP unit requests an IP address from the FortiGate unit, enters discovery mode and should quickly find the FortiGate WiFi controller. This is also known as a wirecloset deployment. See "Wirecloset and Gateway deployments" below.

Wirecloset deployment

Switched Connection: The FortiAP unit is connected to the FortiGate WiFi controller by an Ethernet switch operating in L2 switching mode or L3 routing mode. There must be a routable path between the FortiAP unit and the FortiGate unit and ports 5246 and 5247 must be open. This is also known as a gateway deployment. See Gateway Deployment below.

Gateway Deployment

Connection over WAN: The FortiGate WiFi controller is off-premises and connected by a VPN tunnel to a local FortiGate. In this method of connectivity its best to configure each FortiAP with the static IP address of the WiFi controller. Each FortiAP can be configured with three WiFi controller IP addresses for redundant failover. This is also known as a datacenter remote management deployment. See Remote deployment below.

Remote deployment

Discovering and authorizing APs

After you prepare your FortiGate, you can connect your APs to discover them using the discovery methods described earlier. To prepare the FortiGate, you need to

- Configure the network interface to which the AP will connect.
- Configure DHCP service on the interface to which the AP will connect.
- Optionally, preauthorize FortiAP units. They will begin to function when connected.
- Connect the AP units and let the FortiGate unit discover them.
- Enable each discovered AP and configure it or assign it to an AP profile.

Configuring the network interface for the AP unit

The interface to which you connect your wireless access point needs an IP address. No administrative access, DNS Query service or authentication should be enabled.

To configure the interface for the AP unit - web-based manager

1. Go to **Network > Interfaces** and edit the interface to which the AP unit connects.
2. Set **Addressing Mode** to **Dedicate to Extension Device**.
3. Enter the IP address and netmask to use.
This FortiGate unit automatically configures a DHCP server on the interface that will assign the remaining higher addresses up to .254 to FortiAP units. For example, if the IP address is 10.10.1.100, the FortiAP units will be assigned 10.10.1.101 to 10.10.1.254. To maximize the available addresses, use the .1 address for the interface: 10.10.1.1, for example.
4. Select **OK**.

To configure the interface for the AP unit - CLI

In the CLI, you must configure the interface IP address and DHCP server separately.

```
config system interface
  edit port3
    set mode static
    set ip 10.10.70.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set interface "dmz"
    config ip-range
      edit 1
        set end-ip 10.10.70.254
        set start-ip 10.10.70.2
      end
    set netmask 255.255.255.0
    set vci-match enable
    set vci-string "FortiAP"
  end
end
```

The optional `vci-match` and `vci-string` fields ensure that the DHCP server will provide IP addresses only to FortiAP units.

Pre-authorizing a FortiAP unit

If you enter the FortiAP unit information in advance, it is authorized and will begin to function when it is connected.

To pre-authorize a FortiAP unit

1. Go to **WiFi & Switch Controller > Managed FortiAPs** and select **Create New**.
On some models the **WiFi Controller** menu is called **WiFi & Switch Controller**.
2. Enter the **Serial Number** of the FortiAP unit.
3. Configure the **Wireless Settings** as required.
4. Select **OK**.

Enabling and configuring a discovered AP

Within two minutes of connecting the AP unit to the FortiGate unit, the discovered unit should be listed on **WiFi Controller > Managed FortiAPs** page. After you select the unit, you can authorize, edit or delete it.

Discovered access point unit

<div> + Create New Edit Delete Refresh Authorize </div> <div> AP Radio Managed FortiAPs 0/32 </div>								
Mesh	Access Point	State	Connected Via	SSIDs	Channel	Clients	OS Version	FortiAP Profile
	FP221C3X14019926	?	192.168.2.2	Radio 1: Radio 2: Student-net	Radio1: 0 Radio2: 0	Radio 1: 0 Radio 2: 0		FAP221C-default

When you authorize (enable) a FortiAP unit, it is configured by default to use the default FortiAP profile (determined by model). You can create and select a different profile if needed. The FortiAP profile defines the entire configuration for the AP.

To add and configure the discovered AP unit - web-based manager

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
This configuration also applies to local WiFi radio on FortiWiFi models.
2. Select the FortiAP unit from the list and edit it.
3. Optionally, enter a **Name**. Otherwise, the unit will be identified by serial number.
4. Select **Authorize**.
5. Select a **FortiAP Profile**.
6. Select **OK**.

The physical access point is now added to the system. If the rest of the configuration is complete, it should be possible to connect to the wireless network through the AP.

To add the discovered AP unit - CLI

First get a list of the discovered access point unit serial numbers:

```
get wireless-controller wtp
```

Add a discovered unit and associate it with AP-profile1, for example:

```
config wireless-controller wtp
  edit FAP22A3U10600118
    set admin enable
    set wtp-profile AP-profile1
  end
```

To view the status of the added AP unit

```
config wireless-controller wtp
  edit FAP22A3U10600118
  get
```

The `join-time` field should show a time, not "N/A". See the preceding web-based manager procedure for more information.

Disable automatic discovery of unknown FortiAPs

By default, the FortiGate adds newly discovered FortiAPs to the Managed FortiAPs list, awaiting the administrator's authorization. Optionally, you can disable this automatic registration function to avoid adding unknown FortiAPs. A FortiAP will be registered and listed only if its serial number has already been added manually to the Managed FortiAPs list. AP registration is configured on each interface.

To disable automatic discovery and registration, enter the following command:

```
config system interface
  edit port15
```

```
set ap-discover disable
end
```

Automatic authorization of extension devices

To simplify adding FortiAP or FortiSwitch devices to your network, you can enable automatic authorization of devices as they are connected, instead of authorizing each one individually.

This feature is only configurable in the CLI.

To enable automatic authorization on all dedicated interfaces

```
config system global
set auto-auth-extension-device enable
end
```

To enable automatic authorization per-interface

```
config system interface
edit <port>
set auto-auth-extension-device enable
end
```

Assigning the same profile to multiple FortiAP units

The same profile can now be applied to multiple managed FortiAP units at the same time. To do this, do the following:

1. Go to **WiFi & Switch Controller > Managed FortiAPs** to view the AP list.
2. Select all FortiAP units you wish to apply the profile to.
3. Right click on one of the selected FortiAPs and select **Assign Profile**.
4. Choose the profile you wish to apply.

Overriding the FortiAP profile

In the FortiAP configuration **WiFi & Switch Controller > Managed FortiAPs**, there several radio settings under **Override Radio 1** and **Override Radio 2** to choose a value independently of the FortiAP profile setting. When each of the radios are disabled, you will see what the FortiAP Profile has each of the settings configured to.

Band	The available options depend on the capability of the radio. Overriding Band also overrides Channels . Make appropriate settings in Channels .
Channels	Choose channels. The available channels depend on the Band.
TX Power Control	If you enable Auto , adjust to set the power range in dBm. If you enable Manual , adjust the slider. The 100% setting is the maximum power permitted in your region. See Configuring a WiFi LAN on page 1065 .
SSIDs	Select between Auto or Manual . Selecting Auto eliminates the need to re-edit the profile when new SSIDs are created. However, you can still select SSIDs individually using Manual .

To override radio settings in the CLI

In this example, Radio 1 is set to 802.11n on channel 11, regardless of the profile setting.

```
config wireless-controller wtp
edit FP221C3X14019926
config radio-1
set override-band enable
set band 802.11n
set override-channel enable
set channel 11
end
```

Override settings are available for band, channel, vaps (SSIDs), and txpower.

Outside of configuring radio settings, you can also override FortiAP LED state, WAN port mode, IP Fragmentation prevention method, spectrum analysis, split tunneling, and login password settings.

Accessing the FortiAP CLI through the FortiGate unit

Enable remote login for the FortiAP. In the FortiAP Profile for this FortiAP, enable remote access.

Connecting to the FortiAP CLI

The FortiAP unit has a CLI through which some configuration options can be set. You can access the CLI using Telnet.

To access the FortiAP unit CLI through the FortiAP Ethernet port

1. Connect your computer to the FortiAP Ethernet interface, either directly with a cross-over cable or through a separate switch or hub.
2. Change your computer's IP address to 192.168.1.3
3. Telnet to IP address 192.168.1.2.
Ensure that FortiAP is in a private network with no DHCP server for the static IP address to be accessible.
4. Login with user name admin and no password.
5. Enter commands as needed.
6. Optionally, use the `passwd` command to assign an administrative password for better security.
7. Save the configuration by entering the following command:

```
cfg -c .
```
8. Unplug the FortiAP and then plug it back in, in order for the configuration to take effect

Accessing the FortiAP CLI through the FortiGate

After the FortiAP has been installed, physical access to the unit might be inconvenient. You can access a connected FortiAP unit's CLI through the FortiGate unit that controls it.

To enable remote access to the FortiAP CLI

In the CLI, edit the FortiAP Profile that applies to this FortiAP.

```
config wireless-controller wtp-profile
edit FAP221C-default
set allowaccess telnet
end
```

FortiAP now supports HTTPS and SSH administrative access, as well as HTTP and Telnet. Use the command above to set administrative access to `telnet`, `http`, `https`, or `ssh`.

To access the FortiAP unit CLI through the FortiGate unit - GUI

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
2. In the list, right-click the FortiAP unit and select **>_Connect to CLI**.
A detached Console window opens.
3. At the FortiAP login prompt, enter `admin`. When you are finished using the FortiAP CLI, enter `exit`.

To access the FortiAP unit CLI through the FortiGate unit - CLI

1. Use the FortiGate CLI `execute telnet` command to access the FortiAP. For example, if the FortiAP unit IP address is 192.168.1.2, enter:

```
execute telnet 192.168.1.2
```
2. At the FortiAP login prompt, enter `admin`. When you are finished using the FortiAP CLI, enter `exit`.

When a WiFi controller has taken control of the FortiAP unit, Telnet access to the FortiAP unit's CLI is no longer available.

Checking and updating FortiAP unit firmware

You can view and update the FortiAP unit's firmware from the FortiGate unit that acts as its WiFi controller.

Checking the FortiAP unit firmware version

Go to **WiFi & Switch Controller > Managed FortiAPs** to view the list of FortiAP units that the FortiGate unit can manage. The **OS Version** column shows the current firmware version running on each AP.

Updating FortiAP firmware from the FortiGate unit

You can update the FortiAP firmware using either the web-based manager or the CLI. Only the CLI method can update all FortiAP units at once.

To update FortiAP unit firmware - web-based manager

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
2. Right-click the FortiAP unit in the list and select **Upgrade Firmware**.
or
Edit the FortiAP entry and select **Upgrade from File** in **FortiAP OS Version**.
3. Select **Browse** and locate the firmware upgrade file.
4. Select **OK**.
5. When the upgrade process completes, select **OK**.
The FortiAP unit restarts.

To update FortiAP unit firmware - CLI

1. Upload the FortiAP image to the FortiGate unit.

For example, the Firmware file is FAP_22A_v4.3.0_b0212_fortinet.out and the server IP address is 192.168.0.100.

```
execute wireless-controller upload-wtp-image tftp FAP_22A_v4.3.0_b0212_fortinet.out 192.168.0.100
```

If your server is FTP, change `tftp` to `ftp`, and if necessary add your user name and password at the end of the command.

2. Verify that the image is uploaded:

```
execute wireless-controller list-wtp-image
```

3. Upgrade the FortiAP units:

```
exec wireless-controller reset-wtp all
```

If you want to upgrade only one FortiAP unit, enter its serial number instead of `all`.

Updating FortiAP firmware from the FortiAP unit

You can connect to a FortiAP unit's internal CLI to update its firmware from a TFTP server on the same network. This method does not require access to the wireless controller.

1. Place the FortiAP firmware image on a TFTP server on your computer.
2. Connect the FortiAP unit to a separate private switch or hub or directly connect to your computer via a cross-over cable.
3. Change your computer's IP address to 192.168.1.3.
4. Telnet to IP address 192.168.1.2.
This IP address is overwritten if the FortiAP is connected to a DHCP environment. Ensure that the FortiAP unit is in a private network with no DHCP server.
5. Login with the username "admin" and no password.
6. Enter the following command.

For example, the FortiAP image file name is FAP_22A_v4.3.0_b0212_fortinet.out.

```
restore FAP_22A_v4.3.0_b0212_fortinet.out 192.168.1.3
```

Advanced WiFi controller discovery

A FortiAP unit can use any of six methods to locate a controller. By default, FortiAP units cycle through all six of the discovery methods. In most cases there is no need to make configuration changes on the FortiAP unit.

There are exceptions. The following section describes the WiFi controller discovery methods in more detail and provides information about configuration changes you might need to make so that discovery will work.

Controller discovery methods

There are six methods that a FortiAP unit can use to discover a WiFi controller. Below is the list of AC discovery methods used in sequence, if the FortiAP's discovery type is set to auto:

1(static) → 2(dhcp) → 3(dns) → 7(forticloud) → 5(multicast) → 6(broadcast)

For every discovery type, FortiAP sends out discovery requests and sets a timer, an interval defined as a random number of seconds (between 2-180, default is 5 seconds), which is set via the CLI:

CLI syntax

```
config wireless-controller timers
    set discovery-interval 5
end
```

After the timeout is reached, FortiAP sends out another discovery request, up to a maximum of 3 times.

After about 3 - 15 seconds, if FortiAP has no AC connection, it will switch to another discovery type and repeat the above process until the last one (**broadcast**) fails, which will lead to SULKING state.

After about 30 seconds, FortiAP will go into an AC_IP_DISCOVER state. After the AC IP is found, it will go to IDLE state, and will eventually go to the DISCOVERY state, and repeat the above process again.

Note that, while the process above is showcasing the auto discovery method, it's recommended to set the AC_DISCOVERY_TYPE to your used method in order to reduce downtime.

Static IP configuration

If FortiAP and the controller are not in the same subnet, broadcast and multicast packets cannot reach the controller. The admin can specify the controller's static IP on the AP unit. The AP unit sends a discovery request message in unicast to the controller. Routing must be properly configured in both directions.

To specify the controller's IP address on a FortiAP unit

```
cfg -a AC_IPADDR_1="192.168.0.100"
```

By default, the FortiAP unit receives its IP address, netmask, and gateway address by DHCP. If you prefer, you can assign these statically.

To assign a static IP address to the FortiAP unit

```
cfg -a ADDR_MODE=STATIC
cfg -a AP_IPADDR="192.168.0.100"
cfg -a AP_NETMASK="255.255.255.0"
cfg -a IPGW=192.168.0.1
cfg -c
```

For information about connecting to the FortiAP CLI, see [Connecting to the FortiAP CLI on page 1097](#).

DHCP

If you use DHCP to assign an IP address to your FortiAP unit, you can also provide the WiFi controller IP address at the same time. This is useful if the AP is located remotely from the WiFi controller and other discovery techniques will not work.

When you configure the DHCP server, configure Option 138 to specify the WiFi controller IP address. You need to convert the address into hexadecimal. Convert each octet value separately from left to right and concatenate them. For example, 192.168.0.1 converts to C0A80001.

If Option 138 is used for some other purpose on your network, you can use a different option number if you configure the AP units to match.

To change the FortiAP DHCP option code

To use option code 139 for example, enter

```
cfg -a AC_DISCOVERY_DHCP_OPTION_CODE=139
```

For information about connecting to the FortiAP CLI, see [Connecting to the FortiAP CLI on page 1097](#).

DNS

The access point can discover controllers through your domain name server (DNS). For the access point to do so, you must configure your DNS to return controller IP addresses in response. Allow DNS lookup of the hostname configured in the AP by using the AP parameter "AC_HOSTNAME_1".

FortiCloud

The access point can discover FortiCloud by doing a DNS lookup of the hardcoded FortiCloud AP controller hostname "apctrl1.fortinet.com". The forticloud AC discovery technique finds the AC info from apctrl1.fortinet.com using HTTPS.

FortiCloud APController: apctrl1.fortinet.com:443 208.91.113.187:443

Broadcast request

The AP unit broadcasts a discovery request message to the network and the controller replies. The AP and the controller must be in the same broadcast domain. No configuration adjustments are required.

Multicast request

The AP unit sends a multicast discovery request and the controller replies with a unicast discovery response message. The AP and the controller do not need to be in the same broadcast domain if multicast routing is properly configured.

The default multicast destination address is 224.0.1.140. It can be changed through the CLI. The address must be same on the controller and AP.

To change the multicast address on the controller

```
config wireless-controller global
  set discovery-mc-addr 224.0.1.250
end
```

To change the multicast address on a FortiAP unit

```
cfg -a AC_DISCOVERY_MC_ADDR="224.0.1.250"
```

For information about connecting to the FortiAP CLI, see [Advanced WiFi controller discovery on page 1099](#).

Wireless client load balancing for high-density deployments

Wireless load balancing allows your wireless network to distribute wireless traffic more efficiently among wireless access points and available frequency bands. FortiGate wireless controllers support the following types of client load balancing:

- Access Point Hand-off - the wireless controller signals a client to switch to another access point.
- Frequency Hand-off - the wireless controller monitors the usage of 2.4GHz and 5GHz bands, and signals clients to switch to the lesser-used frequency.

Load balancing is not applied to roaming clients.

Access point hand-off

Access point handoff wireless load balancing involves the following:

- If the load on an access point (ap1) exceeds a threshold (of for example, 30 clients) then the client with the weakest signal will be signaled by wireless controller to drop off and join another nearby access point (ap2).
- When one or more access points are overloaded (for example, more than 30 clients) and a new client attempts to join a wireless network, the wireless controller selects the least busy access point that is closest to the new client and this access point is the one that responds to the client and the one that the client joins.

Frequency hand-off or band-steering

Encouraging clients to use the 5GHz WiFi band if possible enables those clients to benefit from faster interference-free 5GHz communication. The remaining 2.4GHz clients benefit from reduced interference.

The WiFi controller probes clients to determine their WiFi band capability. It also records the RSSI (signal strength) for each client on each band.

If a new client attempts to join the network, the controller looks up that client's MAC address in its wireless device table and determines if it's a dual band device. If it is not a dual band device, then its allowed to join. If it is a dual band device, then its RSSI on 5GHz is used to determine whether the device is close enough to an access point to benefit from movement to 5GHz frequency.

If both conditions of 1) dual band device and 2) RSSI value is strong, then the wireless controller does not reply to the join request of the client. This forces the client to retry a few more times and then timeout and attempt to join the same SSID on 5GHz. Once the Controller see this new request on 5GHz, the RSSI is again measured and the client is allowed to join. If the RSSI is below threshold, then the device table is updated and the controller forces the client to timeout again. A client's second attempt to connect on 2.4GHz will be accepted.

Configuration

From the web-based manager, edit a custom AP profile and select **Frequency Handoff** and **AP Handoff** as required for each radio on the AP.

From the CLI, you configure wireless client load balancing thresholds for each custom AP profile. Enable access point hand-off and frequency hand-off separately for each radio in the custom AP profile.

```
config wireless-controller wtp-profile
  edit new-ap-profile
    set handoff-rssi <rssi_int>
    set handoff-sta-thresh <clients_int>
    config radio-1
      set frequency-handoff {disable | enable}
      set ap-handoff {disable | enable}
    end
    config radio-2
      set frequency-handoff {disable | enable}
      set ap-handoff {disable | enable}
    end
  end
end
```

Where:

- `handoff-rssi` is the RSSI threshold. Clients with a 5 GHz RSSI threshold over this value are load balanced to the 5GHz frequency band. Default is 25. Range is 20 to 30.

- `handoff-sta-thresh` is the access point handoff threshold. If the access point has more clients than this threshold it is considered busy and clients are changed to another access point. Default is 30, range is 5 to 25.
- `frequency-handoff` enable or disable frequency handoff load balancing for this radio. Disabled by default.
- `ap-handoff` enable or disable access point handoff load balancing for this radio. Disabled by default.

Frequency handoff must be enabled on the 5GHz radio to learn client capability.

FortiAP groups

FortiAP groups facilitate the application of FortiAP profiles to large numbers of FortiAPs. A FortiAP can belong to no more than one FortiAP group. A FortiAP group can include only one model of FortiAP.

Through the VLAN pool feature, a FortiAP group can be associated with a VLAN to which WiFi clients will be assigned. For more on VLAN pool assignment, see [VLAN assignment by VLAN pool](#).

FortiAP groups are only configurable in the CLI Console.

To create a FortiAP group - CLI

In this example, `wtp-group-1` is created for a FortiAP-221C and one member device is added.

```
config wireless-controller wtp-group
  edit wtp-group-1
    set platform-type 221C
    config wtp-list
      edit FP221C3X14019926
    end
  end
end
```

LAN port options

Some FortiAP models have one or more LAN interfaces that can provide wired network access. LAN ports can be

- bridged to the incoming WAN interface
- bridged to one of the WiFi SSIDs that the FortiAP unit carries
- connected by NAT to the incoming WAN interface

There are some differences among FortiAP models.

Models like 11C and 14C have one port labeled WAN and one or more ports labeled LAN. By default, the LAN ports are offline. You can configure LAN port operation in the FortiAP Profile in the GUI (**Wireless Controller > FortiAP Profiles**) or in the CLI (`config wireless-controller wtp-profile, config lan` subcommand).

Models like 320C, 320B, 112D, and 112B have two ports, labeled LAN1 and LAN2. LAN1 acts as a WAN port connecting the FortiAP to a FortiGate or FortiCloud. By default, LAN2 is bridged to LAN1. Other modes of LAN2 operation must be enabled in the CLI:

```
config wireless-controller wtp-profile
  edit <profile_name>
    set wan-port-mode wan-lan
  end
```

By default `wan-port-mode` is set to `wan-only`.

When `wan-port-mode` is set to `wan-lan`, LAN2 Port options are available in the GUI and the CLI the same as the other FortiAP models that have labeled WAN and LAN ports.

Bridging a LAN port with an SSID

Bridging a LAN port with a FortiAP SSID combines traffic from both sources to provide a single broadcast domain for wired and wireless users.

In this configuration

- The IP addresses for LAN clients come from the DHCP server that serves the wireless clients.
- Traffic from LAN clients is bridged to the SSID's VLAN. Dynamic VLAN assignment for hosts on the LAN port is not supported.
- Wireless and LAN clients are on the same network and can communicate locally, via the FortiAP.
- Any host connected to the LAN port will be taken as authenticated. RADIUS MAC authentication for hosts on the LAN port is not supported.

For configuration instructions, see [LAN port options on page 1103](#).

Bridging a LAN port with the WAN port

Bridging a LAN port with the WAN port enables the FortiAP unit to be used as a hub which is also an access point.

In this configuration

- The IP addresses for LAN clients come from the WAN directly and will typically be in the same range as the AP itself.
- All LAN client traffic is bridged directly to the WAN interface.
- Communication between wireless and LAN clients can only occur if a policy on the FortiGate unit allows it.

For configuration instructions, see [LAN port options on page 1103](#).

Configuring FortiAP LAN ports

You can configure FortiAP LAN ports for APs in a FortiAP Profile. A profile applies to APs that are the same model and share the same configuration. If you have multiple models or different configurations, you might need to create several FortiAP Profiles. For an individual AP, it is also possible to override the profile settings.

To configure FortiAP LAN ports - web-based manager

1. If your FortiAP unit has LAN ports, but no port labeled WAN (models 320C, 320B, 112D, and 112B for example), enable LAN port options in the CLI:

```
config wireless-controller wtp-profile
  edit <profile_name>
    set wan-port-mode wan-lan
  end
```
2. Go to **WiFi & Switch Controller > FortiAP Profiles**.
3. Edit the default profile for your FortiAP model or select **Create New**.
4. If you are creating a new profile, enter a **Name** and select the correct **Platform** (model).
5. Select SSIDs.
6. In the **LAN Port** section, set **Mode** to **Bridge to** and select an SSID or **WAN Port** as needed.
On some models with multiple LAN ports, you can set **Mode** to **Custom** and configure the LAN ports individually.

Enable each port that you want to use and select an SSID or **WAN Port** as needed.

7. Select OK.

Be sure to select this profile when you authorize your FortiAP units.

To configure FortiAP LAN ports - CLI

In this example, the default FortiAP-11C profile is configured to bridge the LAN port to the office SSID.

```
config wireless-controller wtp-profile
  edit FAP11C-default
    config lan
      set port-mode bridge-to-ssid
      set port-ssid office
    end
  end
end
```

In this example, the default FortiAP-28C profile is configured to bridge LAN port1 to the office SSID and to bridge the other LAN ports to the WAN port.

```
config wireless-controller wtp-profile
  edit FAP28C-default
    config lan
      set port1-mode bridge-to-ssid
      set port1-ssid office
      set port2-mode bridge-to-wan
      set port3-mode bridge-to-wan
      set port4-mode bridge-to-wan
      set port5-mode bridge-to-wan
      set port6-mode bridge-to-wan
      set port7-mode bridge-to-wan
      set port8-mode bridge-to-wan
    end
  end
end
```

In this example, the default FortiAP-320C profile is configured to bridge the LAN port to the office SSID.

```
config wireless-controller wtp-profile
  edit FAP320C-default
    set wan-port-mode wan-lan
    config lan
      set port-mode bridge-to-ssid
      set port-ssid office
    end
  end
end
```

To configure FortiAP unit LAN ports as a FortiAP Profile override - web-based manager

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
2. Select the FortiAP unit from the list and select **Edit**.
3. Select the **FortiAP Profile**, if this has not already been done.
4. In the **LAN Port** section, select **Override**.
The options for **Mode** are shown.
5. Set **Mode** to **Bridge to** and select an SSID or **WAN Port**, or **NAT to WAN** as needed.
On some models with multiple LAN ports, you can set **Mode** to **Custom** and configure the LAN ports individually.

Enable and configure each port that you want to use.

6. Select OK.

To configure FortiAP unit LAN ports as a FortiAP Profile override - CLI

In this example, a FortiAP unit's configuration overrides the FortiAP Profile to bridge the LAN port to the office SSID.

```
config wireless-controller wtp
  edit FP320C3X14020000
    set wtp-profile FAP320C-default
    set override-wan-port-mode enable
    set wan-port-mode wan-lan
    set override-lan enable
    config lan
      set port-mode bridge-to-ssid
      set port-ssid office
    end
  end
end
```

Preventing IP fragmentation of packets in CAPWAP tunnels

A common problem with controller-based WiFi networks is reduced performance due to IP fragmentation of the packets in the CAPWAP tunnel.

Fragmentation can occur because of CAPWAP tunnel overhead increasing packet size. If the original wireless client packets are close to the maximum transmission unit (MTU) size for the network (usually 1500 bytes for Ethernet networks unless jumbo frames are used) the resulting CAPWAP packets may be larger than the MTU, causing the packets to be fragmented. Fragmenting packets can result in data loss, jitter, and decreased throughput.

The FortiOS/FortiAP solution to this problem is to cause wireless clients to send smaller packets to FortiAP devices, resulting in 1500-byte CAPWAP packets and no fragmentation. The following options configure CAPWAP IP fragmentation control:

```
config wireless-controller wtp-profile
  edit FAP321C-default
    set ip-fragment-preventing {tcp-mss-adjust | icmp-unreachable}
    set tun-mtu-uplink {0 | 576 | 1500}
    set tun-mtu-downlink {0 | 576 | 1500}
  end
end
```

By default, `tcp-mss-adjust` is enabled, `icmp-unreachable` is disabled, and `tun-mtu-uplink` and `tun-mtu-downlink` are set to 0.

To set `tun-mtu-uplink` and `tun-mtu-downlink`, use the default TCP MTU value of 1500. This default configuration prevents packet fragmentation because the FortiAP unit limits the size of TCP packets received from wireless clients so the packets don't have to be fragmented before CAPWAP encapsulation.

The `tcp-mss-adjust` option causes the FortiAP unit to limit the maximum segment size (MSS) of TCP packets sent by wireless clients. The FortiAP does this by adding a reduced MSS value to the SYN packets sent by the FortiAP unit when negotiating with a wireless client to establish a session. This results in the wireless client sending packets that are smaller than the `tun-mtu-uplink` setting, so that when the CAPWAP headers are added, the CAPWAP packets have an MTU that matches the `tun-mtu-uplink` size.

The `icmp-unreachable` option affects all traffic (UDP and TCP) between wireless clients and the FortiAP unit. This option causes the FortiAP unit to drop packets that have the "Don't Fragment" bit set in their IP header and that are large enough to cause fragmentation and then send an ICMP packet -- type 3 "ICMP Destination unreachable" with code 4 "Fragmentation Needed and Don't Fragment was Set" back to the wireless controller. This should cause the wireless client to send smaller TCP and UDP packets.

Overriding IP fragmentation settings on a FortiAP

If the FortiAP Profile settings for IP fragmentation are not appropriate for a particular FortiAP, you can override the settings on that specific unit.

```
config wireless-controller wtp
  edit FAP321C3X14019926
    set override-ip-fragment enable
    set ip-fragment-preventing {tcp-mss-adjust | icmp-unreachable}
    set tun-mtu-uplink {0 | 576 | 1500}
    set tun-mtu-downlink {0 | 576 | 1500}
  end
end
```

LED options

Optionally, the status LEDs on the FortiAP can be kept dark. This is useful in dormitories, classrooms, hotels, medical clinics, hospitals where the lights might be distracting or annoying to occupants.

On the FortiGate, the LED state is controlled in the FortiAP Profile. By default the LEDs are enabled. The setting is CLI-only. For example, to disable the LEDs on FortiAP-221C units controlled by the FAP221C-default profile, enter:

```
config wireless-controller wtp-profile
  edit FAP221C-default
    set led-state disable
  end
```

You can override the FortiAP Profile LED state setting on an individual FortiAP using the CLI. For example, to make sure the LEDs are disabled on one specific unit, enter:

```
config wireless-controller wtp
  edit FAP221C3X14019926
    set override-led-state enable
    set led-state disable
  end
```

The LED state is also controllable from the FortiAP unit itself. By default, the FortiAP follows the FortiAP Profile setting.

LED schedules

Use the command below (`led-schedule`) to assign recurring firewall schedules for illuminating LEDs on the FortiAP. This entry is only available when `led-state` is enabled, at which point LEDs will be visible when at least one of the schedules is valid.

Separate multiple schedule names with a space, as configured under `config firewall schedule group` and `config firewall schedule recurring`.

Syntax

```

config wireless-controller wtp-profile
  edit {name}
    set led-state {enable | disable}
    set led-schedules <name>
  next
end

```

CAPWAP bandwidth formula

The following section provides information on how to calculate the control plane CAPWAP traffic load in local bridging. The formula provided can help estimate the approximate package bandwidth cost. This is important for knowing precisely how much bandwidth is required on a WAN link for a centralized FortiGate managing hundreds of access points.

There are multiple factors that might affect the volume of CAPWAP control traffic, including the number of stations there are and large WiFi events.

The Ethernet/IP/UDP/CAPWAP uplink header cost should be approximately 66 bytes.

The tables below depict basic and commonly used optional CAPWAP bandwidth costs, on a per-AP basis.

Note the following:

- **STA:** The number of stations associated with the FortiAP.
- **ARP scan:** Finds hidden devices in your network.
- **VAP:** The number of VAPS held by the FortiAP.
- **Radio:** The number of radios (maximum of two) enabled by the FortiAP.

Basic per-AP CAPWAP bandwidth costs

Content	Time (seconds)	Payload (byte)	Package bandwidth cost (bps)
Echo Req	30	16	$(66+16)*8/30=21.86$
STA scan	30	$25+20*sta$	$(66+25+20*sta)*8/30=24.26+5.3*sta$
ARP scan	30	$25+18*sta$	$(66+25+18*sta)*8/30=24.26+4.8*sta$
STA CAP	30	$25+19*sta$	$(66+25+19*sta)*8/30=24.26+5.1*sta$
STA stats	1	$25+41*sta$	$(66+25+41*sta)*8/1=728.0+328.0*sta$
VAP stats	15	$40+18*vap$	$(66+40+18*vap)*8/15=56.53+9.6*vap$
Radio stats	15	$25+25*radio$	$(66+25+25*radio)*8/15=48.53+13.3*radio$
Total:			$908.7+343.2*sta+9.6*vap+13.3*radio$

Commonly used optional per-AP CAPWAP bandwidth costs

Content	Time (seconds)	Payload (byte)	Package bandwidth cost (bps)
AP scan	30	25+63*scanned-ap	$(66+25+63*\text{scanned-ap}) * 8 / 30 = 24.26 + 16.8 * \text{scanned-ap}$
Total:			$932.96 + 343.2 * \text{sta} + 9.6 * \text{vap} + 13.3 * \text{radio} + 16.8 * \text{scanned-ap}$

Enabling WIDS features, LLDP, MESH, FortiPresence, and Client Station Locating Service can lead to additional bandwidth consumption.

Example:

There are 100 FortiAPs, with 187 stations distributed among them. Each FortiAP holds five VAPs among their radios, and each enables two radios. The basic CAPWAP bandwidth cost would be:

$$908.7 * 100 + 343.2 * 187 + 9.6 * 5 * 100 + 13.3 * 2 * 100 = \mathbf{162.51\text{kbps}}$$

Additionally, if two FortiAPs enabled "AP scan", and suppose one scans 99 APs in each scan and the other scans 20 APs in each scan, the additional CAPWAP bandwidth cost would be:

$$(24.26 + 16.8 * 99) + (24.26 + 16.8 * 20) = \mathbf{2\text{ kbps}}$$

Enabling LLDP protocol

You can enable the LLDP protocol in the FortiAP Profile via the CLI. Each FortiAP using that profile can then send back information about the switch and port that it is connected to.

To enable LLDP, enter the following:

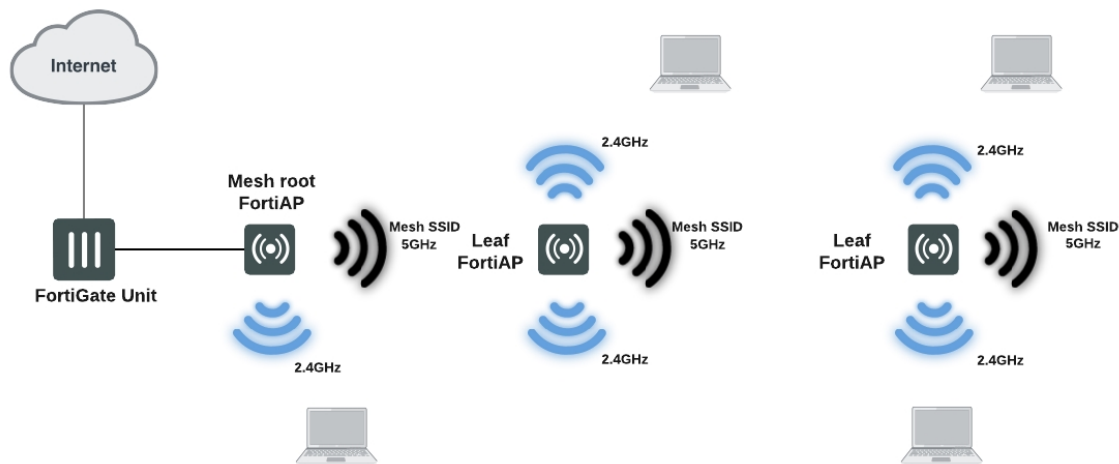

```
config wireless-controller wtp-profile
  edit <profile-name>
    set lldp enable
  end
```

Wireless mesh

The access points of a WiFi network are usually connected to the WiFi controller through Ethernet wiring. A wireless mesh eliminates the need for Ethernet wiring by connecting WiFi access points to the controller by radio. This is useful where installation of Ethernet wiring is impractical.

Overview of wireless mesh

The figure below shows a wireless mesh topology.

A wireless mesh is a multiple access point (AP) network in which only one FortiAP unit is connected to the wired network. The other FortiAPs communicate with the controller over a separate backhaul SSID that isn't available to regular WiFi clients. The AP connected to the network by Ethernet is called the mesh root node. The backhaul SSID carries CAPWAP discovery, configuration, and other communications that would usually be carried on an Ethernet connection.

The root node can be a FortiAP unit or the built-in AP of a FortiWiFi unit. APs that serve regular WiFi clients are called leaf nodes. Leaf APs also carry the mesh SSID for more distant leaf nodes. A leaf node can connect to the mesh SSID directly from the root node or from any of the other leaf nodes. This provides redundancy in case of an AP failure.

All access points in a wireless mesh configuration must have at least one of their radios configured to provide mesh backhaul communication. As with wired APs, when mesh APs start up, they can be discovered by a FortiGate or FortiWiFi unit WiFi controller and authorized to join the network.

The backhaul SSID delivers the best performance when it is carried on a dedicated radio. On a two-radio FortiAP unit, for example, the 5GHz radio could carry only the backhaul SSID while the 2.4GHz radio carries one or more SSIDs that serve users. You can configure background WiFi scanning in this mode.

The backhaul SSID can also share the same radio with SSIDs that serve users. Performance is reduced because the backhaul and user traffic compete for the available bandwidth. Background WiFi scanning isn't available in this mode. One advantage of this mode is that a two-radio AP can offer WiFi coverage on both bands.

Wireless mesh deployment modes

There are two common wireless mesh deployment modes:

Wireless mesh	Access points are connected to a FortiGate or FortiWiFi unit WiFi controller. WiFi users connect to wireless SSIDs in the same way as on non-mesh WiFi networks.
Wireless bridging	Two LAN segments are connected together over a wireless link (the backhaul SSID). On the leaf AP, the Ethernet connection can be used to provide a wired network. Both WiFi and wired users on the leaf AP are connected to the LAN segment to which the root AP is connected.

Firmware requirements

All FortiAP units that are part of the wireless mesh network must be upgraded to FortiAP firmware version 5.0, build 003, or higher. FortiAP-222B units must have their BIOS upgraded to version 400012. The FortiWiFi or FortiGate unit used as the WiFi controller must be running FortiOS firmware version 5.0 or higher.

Types of wireless mesh

A WiFi mesh can provide access to widely-distributed clients. The mesh root AP which is directly connected to the WiFi controller can be either a FortiAP unit or the built-in AP of a FortiWiFi unit that is also the WiFi controller.

FortiAP units used as both mesh root AP and leaf AP

FortiWiFi unit as mesh root AP with FortiAP units as leaf APs

An alternate use of the wireless mesh is as a point-to-point relay. Both wired and WiFi users on the leaf AP side are connected to the LAN segment on the mesh root side.

Point-to-point wireless mesh

Fast-roaming for mesh backhaul link

Mesh implementations for leaf FortiAP can perform background scanning when the leaf AP is associated with the root. Various options for background scanning can be configured with the CLI. See [Mesh variables on page 1219](#) for more details.

Configuring a meshed WiFi network

You need to:

- Create the mesh root SSID.
- Create the FortiAP profile.
- Configure mesh leaf AP units.
- Configure the mesh root AP, either a FortiWiFi unit's local radio or a FortiAP unit.
- Authorize the mesh leaf units when they connect to the WiFi Controller.
- Create security policies.

This section assumes that the end-user SSIDs already exist.

Creating the mesh root SSID

The mesh route SSID is the radio backhaul that conveys the user SSID traffic to the leaf FortiAPs.

To configure the mesh root SSID

1. Go to **WiFi & Switch Controller > SSID** and select **Create New > SSID**.
2. Enter a **Name** for the WiFi interface.
3. In **Traffic Mode**, select **Mesh Downlink**.
4. Enter the **SSID**.
5. Set **Security Mode** to **WPA2 Personal** and enter the **Pre-shared key**.
Remember the key, you need to enter it into the configurations of the leaf FortiAPs.
6. Select **OK**.

Creating the FortiAP profile

Create a FortiAP profile for the meshed FortiAPs. If more than one FortiAP model is involved, you need to create a profile for each model. Typically, the profile is configured so that Radio 1 (5GHz) carries the mesh backhaul SSID while Radio 2 (2.4GHz) carries the SSIDs to which users connect.

For Radio 1, use the **Select SSIDs** option and choose only the backhaul SSID. The radio that carries the backhaul traffic must not carry other SSIDs.

Radio 2 carries user SSIDs and shouldn't carry the backhaul. Use the **Select SSIDs** option and choose the networks that you want to provide.

For more information, see [Configuring a WiFi LAN on page 1065](#).

Configuring the mesh root AP

The mesh root AP can be either a FortiWiFi unit's built-in AP or a FortiAP unit.

To enable a FortiWiFi unit's local radio as mesh root

1. On the FortiWiFi unit, go to **WiFi & Switch Controller > Local WiFi Radio**.
2. Select **Enable WiFi Radio**.
3. In **SSID**, select **Select SSIDs**, then select the mesh root SSID.

4. Optionally, adjust **Tx Power** or select **Auto Tx Power Control**.
5. Select **Apply**.

In a network with multiple wireless controllers, make sure that each mesh root has a unique SSID. Other controllers using the same mesh root SSID might be detected as fake or rogue APs. Go to **WiFi & Switch Controller > SSID** to change the SSID.

To configure a network interface for the mesh root FortiAP unit

1. On the FortiGate unit, go to **Network > Interfaces**.
2. Edit the interface where you will connect the FortiAP unit.
3. Make sure that **Role** is **LAN**.
4. In **Addressing mode**, select **Dedicated to FortiSwitch**.
5. In **IP/Network Mask**, enter an IP address and netmask for the interface.
DHCP will provide addresses to connected devices. To maximize the number of available addresses, the interface address should end with 1, for example 192.168.10.1.
6. Select **OK**.

At this point you can connect the mesh root FortiAP (see below). If you're going to configure leaf FortiAPs through the wireless controller (see ["Configuring a meshed WiFi network" on page 1113](#)), connect the root unit later.

To enable the root FortiAP unit

1. Connect the root FortiAP unit's Ethernet port to the FortiGate network interface that you configured.
2. On the FortiGate unit, go to **WiFi & Switch Controller > Managed FortiAPs**.
If the root FortiAP unit isn't listed, wait 15 seconds and select **Refresh**. Repeat if necessary. If the unit is still missing after a minute or two, power cycle the root FortiAP unit and try again.
3. Right-click the FortiAP entry and choose your profile from the **Assign Profile** submenu.
4. Right-click the FortiAP entry and select **Authorize**.
Initially, the **State** of the FortiAP unit is **Offline**. Periodically click **Refresh** to update the status. Within about two minutes, the state changes to **Online**.
5. Select **OK**.

Configuring the mesh leaf FortiAPs

The FortiAP units that serve as leaf nodes must be preconfigured. This involves changing the FortiAP unit's internal configuration. You can do this by direct connection or through the FortiGate wireless controller.

Method 1: Direct connection to the FortiAP

1. Configure the computer's IP as 192.168.1.3.
2. Connect the computer to the FortiAP unit's Ethernet port and use the default IP address, 192.168.1.2.
3. Log in to the FortiAP as admin. By default, no password is set.
4. Enter the following commands:
 - a. If you're using the GUI, go to **Connectivity > Uplink** and select the **Mesh** option. Then enter the **Mesh AP SSID** and **Mesh AP Password** (pre-shared key).
 - b. If you're using the FortiAP CLI (Telnet or SSH), enter the following commands, substituting your own SSID and password (pre-shared key):

```
cfg -a MESH_AP_TYPE=1
cfg -a MESH_AP_SSID=fortinet.mesh.root
cfg -a MESH_AP_PASSWD=hardtoguess
cfg -c
exit
```

5. Disconnect the computer.
6. Power down the FortiAP.
7. Repeat the preceding steps for each leaf FortiAP.

Method 2: Connecting through the FortiGate unit

1. Connect the Ethernet port on the leaf FortiAP to the FortiGate network interface that you configured for FortiAPs. Connect the FortiAP unit to a power source unless PoE is used.
2. On the FortiGate unit, go to **WiFi & Switch Controller > Managed FortiAPs**.
If the FortiAP unit isn't listed, wait 15 seconds and select **Refresh**. Repeat if necessary. If the unit is still missing after a minute or two, power cycle the FortiAP unit and try again.
3. Select the discovered FortiAP unit and authorize it. Click **Refresh** every 10 seconds until the **State** indicator changes to **Online**.
4. Right-click the FortiAP and select **>_Connect to CLI**. The **CLI Console** window opens. Log in as "admin".
5. Enter the following commands, substituting your own SSID and password (pre-shared key):

```
cfg -a MESH_AP_TYPE=1
cfg -a MESH_AP_SSID=fortinet.mesh.root
cfg -a MESH_AP_PASSWD=hardtoguess
cfg -c
exit
```
6. Disconnect the FortiAP and delete it from the **Managed FortiAP** list.
7. Repeat the preceding steps for each leaf FortiAP.

Authorizing leaf APs

When the root FortiAP is connected and online, apply power to the preconfigured leaf FortiAPs. The leaf FortiAPs will connect themselves wirelessly to the WiFi Controller through the mesh network. You must authorize each unit.

1. On the FortiGate unit, go to **WiFi & Switch Controller > Managed FortiAPs**. Periodically select **Refresh** until the FortiAP unit is listed. This can take up to three minutes.
The **State** of the FortiAP unit should be **Waiting for Authorization**.
2. Right-click the FortiAP entry and choose your profile from the **Assign Profile** submenu.
3. Right-click the FortiAP entry and select **Authorize**.
Initially, the **State** of the FortiAP unit is **Offline**. Periodically click **Refresh** to update the status. Within about two minutes, the state changes to **Online**.

Creating security policies

To permit traffic to flow from the end-user WiFi network to the network interfaces for the Internet and other networks, you need to create security policies and enable NAT. [\(cross reference for WiFi policy creation\)](#)

Viewing the status of the mesh network

On the FortiGate unit, go to **WiFi & Switch Controller > Managed FortiAPs** to view the list of APs.

+ Create New ✎ Edit 🗑 Delete 🔄 Refresh				AP	Radio	Managed FortiAPs	2/32

Configuring a point-to-point bridge

To connect two wired network segments using a WiFi link, you can create a point-to-point bridge. The effect is the same as connecting the two network segments to the same wired switch.

You need to:

- Configure a mesh-backhaul SSID and a mesh root AP as described in ["Configuring the mesh root AP" on page 1113](#).
Note: The mesh root AP for a point-to-point bridge must be a FortiAP unit, not the internal AP of a FortiWiFi unit.
- Configure a mesh leaf FortiAP as described in ["Configuring the mesh leaf FortiAPs" on page 1114](#) and add these steps to configure the Ethernet bridge:
 - If you're using the FortiAP web-based manager, select **Ethernet Bridge**
 - If you're using the FortiAP CLI, insert the following command before the line reading `cfg -c`:
`cfg -a MESH_ETH_BRIDGE=1`
- Connect the local wired network to the Ethernet port on the mesh leaf FortiAP unit. Users are assigned IP addresses from the DHCP server on the wired network connected to the mesh root FortiAP unit.

In general, the mesh-Ethernet bridge automatically detects VLAN ID tags in data packets and allows them to pass. When necessary, you can configure VLAN IDs for permanent support in a mesh-Ethernet bridge. To do this, enter the following commands in the mesh leaf FortiAP CLI:

```
cfg -a MESH_ETH_BRIDGE_VLANS=100,200,300
cfg -c
```

Hotspot 2.0

Hotspot 2.0 Access Network Query Protocol (ANQP) is a query and response protocol that defines seamless roaming services offered by an AP. The following CLI commands are available under `config wireless-controller`, to configure Hotspot 2.0 ANQP.

Syntax

```
config wireless-controller hotspot20 anqp-3gpp-cellular
  edit {name}
    config mcc-mnc-list
      edit {id}
        set id {integer}
        set mcc {string}
        set mnc {string}
      next
    next
  end

config wireless-controller hotspot20 anqp-ip-address-type
  edit {name}
    set ipv6-address-type {option}
    set ipv4-address-type {option}
  next
end

config wireless-controller hotspot20 anqp-nai-realm
  edit {name}
    config nai-list
      edit {name}
        set encoding {enable | disable}
        set nai-realm {string}
        config eap-method
          edit {index}
            set index {integer}
            set method {option}
            config auth-param
              edit {index}
                set index {integer}
                set id {option}
                set val {option}
              next
            next
          next
        next
      next
    next
  end

config wireless-controller hotspot20 anqp-network-auth-type
  edit {name}
    set auth-type {option}
    set url {string}
  next
end
```

```
config wireless-controller hotspot20 anqp-roaming-consortium
  edit {name}
    config oi-list
      edit {index}
        set index {integer}
        set oi {string}
        set comment {string}
      next
    next
  end

config wireless-controller hotspot20 anqp-venue-name
  edit {name}
    config value-list
      edit {index}

            next
        next
    end
```

Combining WiFi and wired networks with a software switch

Combining WiFi and wired networks with a software switch

A WiFi network can be combined with a wired LAN so that WiFi and wired clients are on the same subnet. This is a convenient configuration for users. Note that software switches are only available if your FortiGate is in Interface mode.

Wireless Mesh features cannot be used in conjunction with this configuration because they enable the FortiAP Local Bridge option.

To create the WiFi and wired LAN configuration, you need to:

- Configure the SSID so that traffic is tunneled to the WiFi controller.
- Configure a software switch interface on the FortiGate unit with the WiFi and internal network interface as members.
- Configure Captive Portal security for the software switch interface.

To configure the SSID - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and select **Create New**.
2. Enter:

Interface name	A name for the new WiFi interface, <code>homenet_if</code> for example.
Traffic Mode	Tunnel to Wireless Controller
SSID	The SSID visible to users, <code>homenet</code> for example.
Security Mode Data Encryption Preshared Key	Configure security as you would for a regular WiFi network.

3. Select **OK**.
4. Go to **WiFi & Switch Controller > Managed FortiAPs**, select the FortiAP unit for editing.
5. Authorize the FortiAP unit.
The FortiAP unit can carry regular SSIDs in addition to the Bridge SSID.

To configure the SSID - CLI

This example creates a WiFi interface “homenet_if” with SSID “homenet” using WPA-Personal security, passphrase “Fortinet1”.

```
config wireless-controller vap
  edit "homenet_if"
    set vdom "root"
    set ssid "homenet"
```

```

        set security wpa-personal
        set passphrase "Fortinet1"
    end
    config wireless-controller wtp
        edit FAP22B3U11005354
            set admin enable
            set vaps "homenet_if"
        end
    end

```

To configure the FortiGate software switch - web-based manager

1. Go to **Network > Interfaces** and select **Create New > Interface**.
2. Enter:

Interface Name	A name for the new interface, <code>homenet_nw</code> for example.
Type	Software Switch
Physical Interface Members	Add <code>homenet_if</code> and the internal network interface.
Addressing mode	Select Manual and enter an address, for example <code>172.16.96.32/255.255.255.0</code>
DHCP Server	Enable and configure an address range for clients.
Security Mode	Select Captive Portal . Add the permitted User Groups .

3. Select **OK**.

To configure the FortiGate unit - CLI

```

config system interface
    edit homenet_nw
        set ip 172.16.96.32 255.255.255.0
        set type switch
        set security-mode captive-portal
        set security-groups "Guest-group"
    end
config system interface
    edit homenet_nw
        set member "homenet_if" "internal"
    end

```

VLAN configuration

If your environment uses VLAN tagging, you assign the SSID to a specific VLAN in the CLI. For example, to assign the `homenet_if` interface to VLAN 100, enter:

```

config wireless-controller vap
    edit "homenet_if"
        set vlanid 100
    end

```

Additional configuration

The configuration described above provides communication between WiFi and wired LAN users only. To provide access to other networks, create appropriate firewall policies between the software switch and other interfaces.

FortiAP local bridging (Private cloud-managed AP)

A FortiAP unit can provide WiFi access to a LAN, even when the wireless controller is located remotely. This configuration is useful for the following situations:

- Installations where the WiFi controller is remote and most of the traffic is local or uses the local Internet gateway
- Wireless-PCI compliance with remote WiFi controller
- Telecommuting, where the FortiAP unit has the WiFi controller IP address pre-configured and broadcasts the office SSID in the user's home or hotel room. In this case, data is sent in the wireless tunnel across the Internet to the office and you should enable encryption using DTLS.

Remotely-managed FortiAP providing WiFi access to local network

On the remote FortiGate wireless controller, the WiFi SSID is created with the **Bridge with FortiAP Interface** option selected. In this mode, no IP addresses are configured. The WiFi and Ethernet interfaces on the FortiAP behave as a switch. WiFi client devices obtain IP addresses from the same DHCP server as wired devices on the LAN.

The local bridge feature cannot be used in conjunction with Wireless Mesh features.

Block-Intra-SSID Traffic is available in Bridge mode. This is useful in hotspot deployments managed by a central FortiGate, but would also be useful in cloud deployments. Previously, this was only supported in Tunnel mode.

To configure a FortiAP local bridge - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and select **Create New > SSID**.
2. Enter:

Interface name	A name for the new WiFi interface.
Traffic Mode	Local bridge with FortiAP's Interface
SSID	The SSID visible to users.
Security Mode Data Encryption Preshared Key	Configure security as you would for a regular WiFi network.

3. Select **OK**.
4. Go to **WiFi & Switch Controller > Managed FortiAPs** and select the FortiAP unit for editing.
5. Authorize the FortiAP unit.
The FortiAP unit can carry regular SSIDs in addition to the Bridge SSID.

SSID configured for local bridge operation

New Interface

Interface Name

Type

Traffic Mode Local bridge with FortiAP's Int...

WiFi Settings

SSID

Security Mode

Pre-shared Key (8 - 63 characters)

Allow New WiFi Client Connections When Controller Is Down ☐

Schedule

Maximum Clients ☐

Optional VLAN ID

To configure a FortiAP local bridge - CLI

This example creates a WiFi interface “branchbridge” with SSID “LANbridge” using WPA-Personal security, passphrase “Fortinet1”.

```
config wireless-controller vap
  edit "branchbridge"
    set vdom "root"
    set ssid "LANbridge"
    set local-bridging enable
    set security wpa-personal
    set passphrase "Fortinet1"
  end
config wireless-controller wtp
  edit FAP22B3U11005354
    set admin enable
    set vaps "branchbridge"
  end
```

Note that:

- Disabling local-bridging forcefully disables local-standalone. Also, disabling either local-bridging or local-standalone forcefully disables intra-vap-privacy.
 - Enabling intra-vap-privacy forcefully disables local-standalone.
 - Enabling local-standalone forcefully enables local-bridging also.
-

Continued FortiAP operation when WiFi controller connection is down

The wireless controller, or the connection to it, might occasionally become unavailable. During such an outage, clients already associated with a bridge mode FortiAP unit continue to have access to the WiFi and wired networks. Optionally, the FortiAP unit can also continue to authenticate users if the SSID meets these conditions:

- **Traffic Mode is Local bridge with FortiAP's Interface.**
In this mode, the FortiAP unit does not send traffic back to the wireless controller.
- **Security Mode is WPA2 Personal.**
These modes do not require the user database. In WPA2 Personal authentication, all clients use the same pre-shared key which is known to the FortiAP unit.
- **Allow New WiFi Client Connections When Controller is down** is enabled.
This field is available only if the other conditions have been met.

The "LANbridge" SSID example would be configured like this in the CLI:

```
config wireless-controller vap
  edit "branchbridge"
    set vdom "root"
    set ssid "LANbridge"
    set local-bridging enable
    set security wpa-personal
    set passphrase "Fortinet1"
    set local-authentication enable
  end
```

Using bridged FortiAPs to increase scalability

The FortiGate wireless controller can support more FortiAP units in local bridge mode than in the normal mode. But this is only true if you configure some of your FortiAP units to operate in remote mode, which supports only local bridge mode SSIDs.

The Managed FortiAP page (**WiFi & Switch Controller > Managed FortiAPs**) shows at the top right the current number of Managed FortiAPs and the maximum number that can be managed, “5/64” for example. The maximum number, however, is true only if all FortiAP units operate in remote mode. For more detailed information, consult the Maximum Values Table. For each FortiGate model, there are two maximum values for managed FortiAP units: the total number of FortiAPs and the number of FortiAPs that can operate in normal mode.

To configure FortiAP units for remote mode operation

1. Create at least one SSID with **Traffic Mode** set to **Local bridge with FortiAP's Interface**.
2. Create a custom AP profile that includes *only* local bridge SSIDs.
3. Configure each managed FortiAP unit to use the custom AP profile. You also need to set the FortiAP unit's `wtp-mode` to `remote`, which is possible only in the CLI. The following example uses the CLI both to set `wtp-mode` and select the custom AP profile:

```
config wireless-controller wtp
  edit FAP22B3U11005354
    set wtp-mode remote
    set wtp-profile 220B_bridge
  end
```

Using remote WLAN FortiAPs

Remote WLAN FortiAP models enable you to provide a pre-configured WiFi access point to a remote or traveling employee. Once plugged in at home or in a hotel room, the FortiAP automatically discovers the enterprise FortiGate WiFi controller over the Internet and broadcasts the same wireless SSID used in the corporate office. Communication between the WiFi controller and the FortiAP is secure, eliminating the need for a VPN.

Split tunneling

By default, all traffic from the remote FortiAP is sent to the FortiGate WiFi controller. If split tunneling is configured, only traffic destined for the corporate office networks is routed to the FortiGate. Other general Internet traffic is routed unencrypted through the local gateway. Split tunneling avoids loading the FortiGate with unnecessary traffic and allows direct access to local private networks at the location of the FortiAP even if the connection to the WiFi controller goes down.

By default, split tunneling options are not visible in the FortiGate GUI. You can make these options visible using the following CLI command:

```
config system settings
    set gui-fortiap-split-tunneling enable
end
```

Split tunneling is configured in **Managed FortiAPs**, **FortiAP Profiles**, and enabled in the **SSID**.

Configuring the FortiGate for remote FortiAPs

This section assumes that you have already defined SSIDs and now want to make them available to remote FortiAPs.

- Create FortiAP profiles for the Remote LAN FortiAP models
- If split tunneling will be used
 - configure override split tunneling in Managed FortiAPs
 - enable Split Tunneling in the SSID
 - configure the split tunnel networks in the FortiAP profile

Override Split tunneling

Go to **WiFi & Switch Controller > Managed FortiAPs** and edit your managed APs. When preconfiguring the AP to connect to your FortiGate WiFi controller, you can choose to override split tunneling, optionally including the local subnet of the FortiAP.

Creating FortiAP profiles

If you were not already using Remote LAN FortiAP models, you will need to create FortiAP profiles for them. In the FortiAP profile, you specify the SSIDs that the FortiAP will broadcast. For more information, see ["Creating a FortiAP profile" on page 1068](#).

Configuring split tunneling - FortiGate GUI

Go to **WiFi & Switch Controller > SSID** and edit your SSID. In the **WiFi Settings** section, enable **Split Tunneling**.

Go to **WiFi Controller > FortiAP Profiles** and edit the FortiAP Profile(s) that apply to the AP types used in the WiFi network. In the **Split Tunneling** section, enable **Include Local Subnet** and **Split Tunneling Subnet(s)**, where you can enter a list all of the destination IP address ranges that should **not** be routed through the the FortiGate WiFi controller. Packets for these destinations will instead be routed through the remote gateway local to the FortiAP.

The list of split tunneling subnets includes public Internet destinations and private subnets local to the FortiAP. Split tunneling public Internet destinations reduces traffic through the FortiGate unit. Split tunneling local private subnets allows these networks to be accessible to the client behind the FortiAP. Otherwise, private network IP destinations are assumed to be behind the FortiGate WiFi controller.

Configuring split tunneling - FortiGate CLI

In this example, split tunneling is configured on the example-ssid WiFi network. On FortiAP model 21D, traffic destined for the 192.168.x.x range will not be routed through the FortiGate WiFi controller. This private IP address range is typically used as a LAN by home routers.

```
config wireless-controller vap
  edit example-ssid
    set split-tunneling enable
  end

config wireless-controller wtp-profile
  edit FAP21D-default
    set split-tunneling-acl-local-ap-subnet enable
    config split-tunneling-acl
      edit 1
        set dest-ip 192.168.0.0 255.255.0.0
      end
    end
  end
```

To enter multiple subnets, create a split-tunneling-acl entry for each one.

Overriding the split tunneling settings on a FortiAP

If the FortiAP Profile split tunneling settings are not appropriate for a particular FortiAP, you can override the settings on that unit.

```
config wireless-controller wtp
  edit FAP321C3X14019926
    set override-split-tunnel enable
    set split-tunneling-acl-local-ap-subnet enable
    config split-tunneling-acl
      edit 1
        set dest-ip 192.168.10.0 255.255.255.0
      end
    end
  end
```

Configuring the FortiAP units

Prior to providing a Remote WLAN FortiAP unit to an employee, you need to preconfigure the AP to connect to your FortiGate WiFi controller.

To pre-configure a FortiAP

1. Connect the FortiAP to the FortiGate unit.
2. Go to **WiFi & Switch Controller > Managed FortiAPs** and wait for the FortiAP to be listed. Click **Refresh** periodically to see the latest information. Note the **Connected Via** IP address.
3. Go to **Dashboard**. In the CLI Console, log into the FortiAP CLI.
For example, if the IP address is 192.168.1.4, enter:

```
exec telnet 192.168.1.4
```

Enter *admin* at the login prompt. By default, no password is set.
4. Enter the following commands to set the FortiGate WiFi controller IP address. This should be the FortiGate Internet-facing IP address, in this example 172.20.120.142.

```
cfg -a AC_IPADDR_1=172.20.120.142  
cfg -c
```
5. Enter *exit* to log out of the FortiAP CLI.

Preauthorizing FortiAP units

By preauthorizing FortiAP units, you facilitate their automatic authorization on the network. Also, you can assign each unit a unique name, such as the employee's name, for easier tracking.

1. Go to **WiFi & Switch Controller > Managed FortiAPs** and create a new entry.
2. Enter the **Serial Number** of the FortiAP unit and give it a **Name**. Select the appropriate **FortiAP Profile**.
3. Click **OK**.

Repeat this process for each FortiAP.

Features for high-density deployments

High-density environments such as auditoriums, classrooms, and meeting rooms present a challenge to WiFi providers. When a large number of mobile devices try to connect to a WiFi network, difficulties arise because of the limited number of radio channels and interference between devices.

FortiOS and FortiAP devices provide several tools to mitigate the difficulties of high-density environments.

Multiple FortiAP firmware upgrades at once

Administrators can configure multiple FortiAP and FortiSwitch firmware upgrades to occur in one click (under **WiFi & Switch Controller > Managed FortiAPs**), removing the need to upgrade each device one at a time.

Power save feature

Occasionally, voice calls can become disrupted. One way to alleviate this issue is by controlling the power save feature, or to disable it altogether.

Manually configure packet transmit optimization settings by entering the following command:

```
config wireless-controller wtp-profile
edit <name>
config <radio-1> | <radio-2>
set transmit-optimize {disable | power-save | aggr-limit | retry-limit | sendbar}
```

- **disable:** Disable transmit optimization.
- **power-save:** Mark a client as power save mode if excessive transmit retries happen.
- **aggr-limit:** Set aggregation limit to a lower value when data rate is low.
- **retry-limit:** Set software retry limit to a lower value when data rate is low.
- **send-bar:** Do not send BAR frame too often.

11n radio powersave optimization

The following `powersave-optimize` parameters (under `config radio`) are used for 11n radios to optimize system performance for specific situations.

- **tim:** Set traffic indication map (TIM) bit for client in power save mode. TIM bit mask indicates to any sleeping listening stations if the AP has any buffered frames present. If enabled, the AP will always indicate to the connected client that there is a packet waiting in the AP, so it will help to prevent the client from entering a sleep state.
- **ac-vo:** Use Access Category (AC) Voice (VO) priority to send packets in the power save queue. AC VO is one of the highest classes/priority levels used to ensure quality of service (QoS). If enabled, when a client returns from a sleep state, the AP will send its buffered packet using a higher priority queue, instead of the normal priority queue.
- **no-obss-scan:** Do not put Overlapping Basic Service Set (OBSS), or high-noise (i.e. non-802.11), scan IE into a Beacon or Probe Response frame.
- **no-11b-rate:** Do not send frame using 11b data rate.
- **client-rate-follow:** Adapt transmitting PHY rate with receiving PHY rate from client. If enabled, the AP will integrate the current client's transmission PHY rate into its rate adaptation algorithm for transmitting.

Broadcast packet suppression

You can use broadcast packet suppression to reduce the traffic on your WiFi networks. In addition, some broadcast packets are unnecessary or even potentially detrimental to the network and should be suppressed. To configure broadcast suppression for each virtual access point, enter the following commands:

```
config wireless-controller vap
  edit <name>
    set broadcast-suppression {dhcp-up | dhcp-down | dhcp-starvation | arp-known | arp-unknown | arp-reply | arp-poison | arp-proxy | netbios-ns | netbios-ds | ipv6 | all-other-mc | all-other-bc}
  end
```

By default, both the `dhcp-up` and `arp-known` options are enabled. The following example leaves the default settings in place and configures a virtual access point to suppress:

- unnecessary DHCP downlink broadcast packets
- broadcast ARP requests for unknown wireless clients
- broadcast packets not covered by any of the other options

```
config wireless-controller vap
  edit <name>
    set broadcast-suppression dhcp-down arp-unknown all-other-bc
  end
```

Option	Description
<code>dhcp-up</code>	Suppress unnecessary DHCP uplink broadcast packets and prevent malicious WiFi clients from acting as DHCP servers. Default setting.
<code>dhcp-down</code>	Suppress unnecessary DHCP downlink broadcast packets and prevent malicious WiFi clients from acting as DHCP servers.
<code>dhcp-starvation</code>	Suppress DHCP starvation request messages. Prevent clients from making multiple requests and depleting the DHCP address pool.
<code>arp-known</code>	Suppress broadcast ARP for known wireless clients. Forward ARP packets to the destination client as a unicast packet and prevents them from reaching other clients. Default setting.
<code>arp-unknown</code>	Suppress broadcast ARP for unknown wireless clients.
<code>arp-reply</code>	Convert broadcast packet ARP replies to unicast and send them to clients listed on the destination MAC.
<code>arp-poison</code>	Suppress ARP poison messages from wireless clients. Prevent clients from spoofing ARP messages.
<code>arp-proxy</code>	Reply to ARP requests for wireless clients as a proxy. Generate ARP reply packets as a proxy and suppress broadcast packets. The <code>arp-known</code> option must be set for <code>arp-proxy</code> to work.
<code>netbios-ns</code>	Suppress NetBIOS name services packets with UDP port 137.

Option	Description
netbios-ds	Suppress NetBIOS datagram services packets with UDP port 138.
ipv6	Suppress IPv6 broadcast packets.
all-other-mc	Suppress multicast packets not covered by any of the specific options.
all-other-bc	Suppress broadcast packets not covered by any of the specific options.

Multicast to unicast conversion

FortiOS provides a multicast enhancement option (disabled by default) that converts multicast streams to unicast and improves performance in WiFi networks. Multicast data, such as streaming audio or video, is sent at a low data rate in WiFi networks. A unicast stream is sent to each client at high data rate that makes more efficient use of air time. To enable multicast-to-unicast conversion, enter the following commands:

```
config wireless-controller vap
  edit <vap_name>
    set multicast-enhance enable
  end
```

Ignore weak or distant clients

Clients beyond the intended coverage area can have some impact on your high-density network. Your APs will respond to these clients' probe signals, consuming valuable air time. You can configure your WiFi network to ignore weak signals that most likely come from beyond the intended coverage area. The settings are available in the CLI:

```
config wireless-controller vap
  edit <vap_name>
    set probe-resp-suppression enable
    set probe-resp-threshold <level_int>
  end
```

vap_name is the SSID name.

probe-resp-threshold is the signal strength in dBm below which the client is ignored. The range is -95 to -20dBm. The default level is -80dBm.

Turn off the 802.11b protocol

By disabling support for the obsolete 802.11b protocol, you can reduce the air time that data frames occupy. These signals will now be sent at a minimum of 6Mbps, instead of 1Mbps. You can set this for each radio in the FortiAP profile, using the CLI:

```
config wireless-controller wtp-profile
  edit <name_string>
    config radio-1
      set powersave-optimize no-11b-rate
    end
```

Disable low data rates

Each of the 802.11 protocols supports several data rates. By disabling the lowest rates, air time is conserved, allowing the channel to serve more users. You can set the available rates for each 802.11 protocol: a, b, g, n, ac. Data rates set as Basic are mandatory for clients to support. Other specified rates are supported.

The 802.11 a, b, and g protocols are specified by data rate. 802.11a can support 6, 9, 12, 18, 24, 36, 48, and 54 Mb/s. 802.11b/g can support 1, 2, 5.5, 6, 9, 12, 18, 24, 36, 48, 54 Mb/s. Basic rates are specified with the suffix "basic", "12-basic" for example. The capabilities of expected client devices need to be considered when deciding the lowest Basic rate.

The 802.11n and ac protocols are specified by the Modulation and Coding Scheme (MCS) Index and the number of spatial streams.

- 802.11n with 1 or 2 spatial streams can support mcs0/1, mcs1/1, mcs2/1, mcs3/1, mcs4/1, mcs5/1, mcs6/1, mcs7/1, mcs8/2, mcs9/2, mcs10/2, mcs11/2, mcs12/2, mcs13/2, mcs14/2, mcs15/2.
- 802.11n with 3 or 4 spatial streams can support mcs16/3, mcs17/3, mcs18/3, mcs19/3, mcs20/3, mcs21/3, mcs22/3, mcs23/3, mcs24/4, mcs25/4, mcs26/4, mcs27/4, mcs28/4, mcs29/4, mcs30/4, mcs31/4.
- 802.11ac with 1 or 2 spatial streams can support mcs0/1, mcs1/1, mcs2/1, mcs3/1, mcs4/1, mcs5/1, mcs6/1, mcs7/1, mcs8/1, mcs9/1, mcs0/2, mcs1/2, mcs2/2, mcs3/2, mcs4/2, mcs5/2, mcs6/2, mcs7/2, mcs8/2, mcs9/2.
- 802.11ac with 3 or 4 spatial streams can support mcs0/3, mcs1/3, mcs2/3, mcs3/3, mcs4/3, mcs5/3, mcs6/3, mcs7/3, mcs8/3, mcs9/3, mcs0/4, mcs1/4, mcs2/4, mcs3/4, mcs4/4, mcs5/4, mcs6/4, mcs7/4, mcs8/4, mcs9/4

Here are some examples of setting basic and supported rates.

```
config wireless-controller vap
edit <vap_name>
    set rates-11a 12-basic 18 24 36 48 54
    set rates-11bg 12-basic 18 24 36 48 54
    set rates-11n-ss34 mcs16/3 mcs18/3 mcs20/3 mcs21/3 mcs22/3 mcs23/3 mcs24/4 mcs25/4
    set rates-11ac-ss34 mcs0/3 mcs1/3 mcs2/3 mcs9/4 mcs9/3
end
```

Limit power

High-density deployments usually cover a small area that has many clients. Maximum AP signal power is usually not required. Reducing the power reduces interference between APs. Fortinet recommends that you use FortiAP automatic power control. You can set this in the FortiAP profile.

1. Go to **WiFi & Switch Controller > FortiAP Profiles** and edit the profile for your AP model.
2. For each radio, enable **Auto TX Power Control** and set the **TX Power Low** and **TX Power High** levels. The default range of 10 to 17dBm is recommended.

Use frequency band load-balancing

In a high-density environment is important to make the best use of the two WiFi bands, 2.4GHz and 5GHz. The 5GHz band has more non-overlapping channels and receives less interference from non-WiFi devices, but not all devices support it. Clients that are capable of 5GHz operation should be encouraged to use 5GHz rather than the 2.4GHz band.

To load-balance the WiFi bands, you enable Frequency Handoff in the FortiAP profile. In the FortiGate web-based manager, go to **WiFi & Switch Controller > FortiAP Profiles** and edit the relevant profile. Or, you can use the CLI:

```
config wireless-controller wtp-profile
edit FAP221C-default
config radio-1
set frequency-handoff enable
end
```

The FortiGate wireless controller continuously performs a scan of all clients in the area and records their signal strength (RSSI) on each band. When Frequency Handoff is enabled, the AP does not reply to clients on the 2.4GHz band that have sufficient signal strength on the 5GHz band. These clients can associate only on the 5GHz band. Devices that support only 2.4GHz receive replies and associate with the AP on the 2.4GHz band.

Setting the handoff RSSI threshold

The FortiAP applies load balancing to a client only if the client has a sufficient signal level on 5GHz. The minimum signal strength threshold is set in the FortiAP profile, but is accessible only through the CLI:

```
config wireless-controller wtp-profile
edit FAP221C-default
set handoff-rssi 25
end
```

`handoff-rssi` has a range of 20 to 30. RSSI is a relative measure. The higher the number, the stronger the signal.

AP load balancing

The performance of an AP is degraded if it attempts to serve too many clients. In high-density environments, multiple access points are deployed with some overlap in their coverage areas. The WiFi controller can manage the association of new clients with APs to prevent overloading.

To load-balance between APs, enable AP Handoff in the FortiAP profile. In the FortiGate web-based manager, go to **WiFi & Switch Controller > FortiAP Profiles** and edit the relevant profile. Or, you can use the CLI:

```
config wireless-controller wtp-profile
edit FAP221C-default
config radio-1
set ap-handoff enable
end
```

When an AP exceeds the threshold (the default is 30 clients), the overloaded AP does not reply to a new client that has a sufficient signal at another AP.

Setting the AP load balance threshold

The thresholds for AP handoff are set in the FortiAP profile, but is accessible only through the CLI:

```
config wireless-controller wtp-profile
edit FAP221C-default
set handoff-sta-thresh 30
set handoff-rssi 25
end
```

`handoff-sta-thresh` sets the number of clients at which AP load balancing begins. It has a range of 5 to 35.

`handoff-rssi` Sets the minimum signal strength that a new client must have at an alternate AP for the overloaded AP to ignore the client. It has a range of 20 to 30. RSSI is a relative measure. The higher the number, the stronger the signal.

Application rate-limiting

To prevent particular application types from consuming too much bandwidth, you can use the FortiOS Application Control feature.

1. Go to **Security Profiles > Application Control**.
You can use the default profile or create a new one.
2. Click the category, select **Traffic Shaping** and then select the priority for the category.
Repeat for each category to be controlled.
3. Select **Apply**.
4. Go to **Policy & Objects > IPv4 Policy** and edit your WiFi security policy.
5. In **Security Profiles**, set **Application Control** ON and select the security profile that you edited.
6. Select **OK**.

AP group management and dynamic VLAN assignment

The FortiGate can create FortiAP Groups, under **WiFi & Switch Controller > Managed FortiAPs** by selecting **Create New > Managed AP Group**, where multiple APs can be managed. AP grouping allows specific profile settings to be applied to many APs all at once that belong to a certain AP group, simplifying the administrative workload.

Note that each AP can only belong to one group.

In addition, VLANs can be assigned dynamically based on the group which an AP belongs. When defining an SSID, under **WiFi & Switch Controller > SSID**, a setting called **VLAN Pooling** can be enabled where you can either assign the VLAN ID of the AP group the device is connected to, to each device as it is detected, or to always assign the same VLAN ID to a specific device. Dynamic VLAN assignment allows the same SSID to be deployed to many APs, avoiding the need to produce multiple SSIDs.

Sharing tunnel SSIDs within a single managed AP between VDOMs as a virtual AP for multi-tenancy

This feature provides the ability to move a tunnel mode VAP into a VDOM, similar to an interface/VLAN in VDOMs. FortiAP is registered into the root VDOM.

Within a customer VDOM, customer VAPs can be created/added. In the root VDOM, the customer VAP can be added to the registered FortiAP. Any necessary firewall rules and interfaces can be configured between the two VDOMs.

Syntax

```
config wireless-controller global
  set wtp-share {enable | disable}
end
```

Manual quarantine of devices on FortiAP (tunnel mode)

Quarantined MAC addresses are blocked on the connected FortiAP from the network and the LAN. When a tunnel VAP is created, a sub-interface named **wqtn** is automatically created under tunnel interface. This sub-interface is added under a software switch.

To quarantine an SSID, go to **WiFi & Switch Controller > SSID**. Edit the SSID, and enable **Quarantine Host** is enabled under **WiFi Settings**.

Alternatively, this can be configured in the CLI Console. This feature consolidates previous CLI syntax for quarantining a host, so that the host does not need to be configured in multiple places (FortiAP and FortiSwitch). Host endpoints can be entered in a single place and the host will be quarantined throughout the access layer devices on the Fortinet Security Fabric.

Note that you can only an SSID in Tunnel Mode.

Syntax - SSID:

```
config wireless-controller vap
  edit <name>
    set quarantine {enable | disable}
  next
end
```

Syntax - Software Switch, DHCP, and User Quarantine

```
config system switch-interface
  edit "wqt.root"
    set vdom "root"
    set member "wqtn.26.AV-Qtn"
  next
end

config system dhcp server
  edit <id>
    set interface "AV-Qtn"
    config ip-range
      edit <id>
        set start-ip 10.111.0.2
        set end-ip 10.111.0.254
      next
    ...
  next
end

config user quarantine
  set quarantine {enable | disable}
end
```

To list stations in quarantine, use the following diagnose command:

```
diagnose wireless-controller wlac -c sta-qtn
```

Host quarantine per SSID

Upon creating or editing an SSID, a **Quarantine Host** option is available to enable (by default) or disable quarantining devices that are connected in Tunnel-mode. The option to quarantine a device is available on **Topology** and **FortiView** WiFi pages.

When a host is put into quarantine VLAN, it will get its IP from the quarantine VLAN's DHCP server, and become part of the quarantined network.

Syntax

```
config wireless-controller vap
  edit <name>
    set quarantine {enable | disable}
  next
end
```

To list all stations in quarantine:

```
diagnose wireless-controller wlac -c sta-qtn
```

Locate a FortiAP with LED blinking

If you have an environment that contains numerous APs, and there is one AP that you need to frequently monitor, you can configure it to blink in the FortiCloud web portal. The blinking AP will be easier to locate.

To start or stop LED blinking of a managed FortiAP, using the GUI:

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
2. Right-click in the row of the device you want to control.
3. In the dialog box, scroll down to **LED Blink** and select **Start** or **Stop**.

The following models support LED blink control through the GUI, operating on FortiAP software 6.0.1, or later:

- FortiAP-112D, 221C, 223C, 224D, 320C, 321C
- FortiAP-S/W2

To start or stop LED blinking of a managed FortiAP, using the CLI:

```
execute wireless-controller led-blink <wtp-id> {on | on 10 | off}
```

The following models support LED blink control through the CLI, operating on FortiAP software 5.6.2, or later:

- FortiAP-112D, 221C, 223C, 224D, 320C, 321C
- FortiAP-S/W2

Wireless controller optimization for large deployment - AP image upgrade

Using the CLI to upgrade FortiAP image is the preferred method especially for large deployments. Use the following execute command to upload the desired FortiAP image on the controller:

```
execute wireless-controller upload-wtp-image
```

After entering the command, reboot the FortiAP devices. This feature allows the administrator to configure all FortiAP devices to download the image from the controller at join time.

Syntax

```
config wireless-controller global
  set image-download {enable | disable}
end
```

To fine-tune this process, in order to deploy FortiAP image upgrades to a subset of devices for pilot testing, use the following command:

```
config wireless-controller wtp
```

```
edit <name>
    set image-download {enable | disable}
next
end
```

Control message off-loading and aeroscout enhancement

Users can configure control message off-loading to optimize performance. This is especially useful in environments where the AP count is around 300-350 (with a device count between 1500 and 3000), where existing users are disconnected and unable to reauthenticate due to high CPU usage. This feature includes aeroscout enhancements.

Syntax

```
config wireless-controller global
    set control-message-offload {evp-frame | areoscout-tag | ap-list | sta-list | sta-cap-
        list | stats | aeroscout-mu}
end

config wireless-controller wtp-profile
    edit <name>
        set control-message-offload {enable | disable}
        config lbs
            set ekahau-blink-mode {enable | disable}
            set aeroscout {enable | disable}
            set aeroscout-server-ip <address>
            set aeroscout-server-port <UDP listening port>
            set aeroscout-mu {enable | disable}
        end
    end
end
```

Protecting the WiFi network

Wireless IDS

The FortiGate Wireless Intrusion Detection System (WIDS) monitors wireless traffic for a wide range of security threats by detecting and reporting on possible intrusion attempts. When an attack is detected the FortiGate unit records a log message.

You can create a WIDS profile to enable these types of intrusion detection:

- Asleep Attack—ASLEAP is a tool used to perform attacks against LEAP authentication.
- Association Frame Flooding—A Denial of Service attack using a large number of association requests. The default detection threshold is 30 requests in 10 seconds.
- Authentication Frame Flooding—A Denial of Service attack using a large number of association requests. The default detection threshold is 30 requests in 10 seconds.
- Broadcasting De-authentication—This is a type of Denial of Service attack. A flood of spoofed de-authentication frames forces wireless clients to de-authenticate, then re-authenticate with their AP.
- EAPOL Packet Flooding—Extensible Authentication Protocol over LAN (EAPOL) packets are used in WPA and WPA2 authentication. Flooding the AP with these packets can be a denial of service attack. Several types of EAPOL packets are detected: EAPOL-FAIL, EAPOL-LOGOFF, EAPOL-START, EAPOL-SUCC.
- Invalid MAC OUI—Some attackers use randomly-generated MAC addresses. The first three bytes of the MAC address are the Organizationally Unique Identifier (OUI), administered by IEEE. Invalid OUIs are logged.
- Long Duration Attack—To share radio bandwidth, WiFi devices reserve channels for brief periods of time. Excessively long reservation periods can be used as a denial of service attack. You can set a threshold between 1000 and 32 767 microseconds. The default is 8200.
- Null SSID Probe Response—When a wireless client sends out a probe request, the attacker sends a response with a null SSID. This causes many wireless cards and devices to stop responding.
- Spoofed De-authentication—Spoofed de-authentication frames are a denial of service attack. They cause all clients to disconnect from the AP.
- Weak WEP IV Detection—A primary means of cracking WEP keys is by capturing 802.11 frames over an extended period of time and searching for patterns of WEP initialization vectors (IVs) that are known to be weak. WIDS detects known weak WEP IVs in on-air traffic.
- Wireless Bridge—WiFi frames with both the fromDS and ToDS fields set indicate a wireless bridge. This will also detect a wireless bridge that you intentionally configured in your network.

You can enable wireless IDS by selecting a WIDS Profile in your FortiAP profile.

To create a WIDS Profile

1. Go to **WiFi & Switch Controller > WIDS Profiles**.
2. Select a profile to edit or select **Create New**.
3. Select the types of intrusion to protect against.
By default, all types are selected.
4. Select **Apply**.

You can also configure a WIDS profile in the CLI using the `config wireless-controller wids-profile` command.

Rogue AP detection

The WIDS profile includes settings for detection of unauthorized (rogue) access points in your wireless network. For more information, see [Wireless network monitoring on page 1145](#).

WIDS client deauthentication rate for DoS attacks

As part of mitigating a Denial of Service (DoS) attack, the FortiGate sends deauthentication packets to unknown clients. In an aggressive attack, this deauthentication activity can prevent the processing of packets from valid clients. A WIDS Profile option in the CLI limits the deauthentication rate.

```
config wireless-controller wids-profile
  edit default
    set deauth-unknown-src-thresh <1-65535>
  end
```

The value set is a measure of the number of deauthorizations per second. 0 means no limit. The default is 10.

WiFi data channel encryption

Optionally, you can apply DTLS encryption to the data channel between the wireless controller and FortiAP units. This enhances security.

There are data channel encryption settings on both the FortiGate unit and the FortiAP units. At both ends, you can enable Clear Text, DTLS encryption, or both. The settings must agree or the FortiAP unit will not be able to join the WiFi network. By default, both Clear Text and DTLS-encrypted communication are enabled on the FortiAP unit, allowing the FortiGate setting to determine whether data channel encryption is used. If the FortiGate unit also enables both Clear Text and DTLS, Clear Text is used.

Data channel encryption settings are located in the FortiAP profile. By default, only Clear Text is supported.

Data channel encryption is software-based and can affect performance. Verify that the system meets your performance requirements with encryption enabled.

Configuring encryption on the FortiGate unit

You can use the CLI to configure data channel encryption.

Enabling encryption

In the CLI, the `wireless wtp-profile` command contains a new field, `dtls-policy`, with options `clear-text` and `dtls-enabled`. To enable encryption in profile1 for example, enter:

```
config wireless-controller wtp-profile
  edit profile1
    set dtls-policy dtls-enabled
  end
```

Configuring encryption on the FortiAP unit

The FortiAP unit has its own settings for data channel encryption.

Enabling CAPWAP encryption - FortiAP web-based manager

1. On the **System Information** page, in **WTP Configuration > AC Data Channel Security**, select one of:
 - Clear Text
 - DTLS Enabled
 - Clear Text or DTLS Enabled (default)
2. Select **Apply**.

Enabling encryption - FortiAP CLI

You can set the data channel encryption using the `AP_DATA_CHAN_SEC` variable: 'clear', or 'ipsec', or 'dtls'.

For example, to set security to DTLS and then save the setting, enter:

```
cfg -a AP_DATA_CHAN_SEC=dtls
cfg -c
```

Protected Management Frames and Opportunistic Key Caching support

Protected Management Frames (PMF) protect some types of management frames like deauthorization, disassociation and action frames. This feature, now mandatory on WiFi certified 802.11ac devices, prevents attackers from sending plain deauthorization/disassociation frames to disrupt or tear down a connection/association. PMF is a Wi-Fi Alliance specification based on IEEE 802.11w.

To facilitate faster roaming client roaming, you can enable Opportunistic Key Caching (OKC) on your WiFi network. When a client associates with an AP, its PMK identifier is sent to all other APs on the network. This eliminates the need for an already-authenticated client to repeat the full EAP exchange process when it roams to another AP on the same network.

Use of PMF and OKC on an SSID is configurable only in the CLI:

```
config wireless-controller vap
  edit <vap_name>
    set pmf {disable | enable | optional}
    set pmf-assoc-comeback-timeout <integer>
    set pmf-sa-query-retry-timeout <integer>
    set okc {disable | enable}
  next
end
```

When `pmf` is set to `optional`, it is considered enabled, but will allow clients that do not use PMF. When `pmf` is set to `enable`, PMF is required by all clients.

Bluetooth Low Energy (BLE) Scan

The FortiGate can configure FortiAP Bluetooth Low Energy (BLE) scan, incorporating Google's BLE beacon profile known as Eddystone, used to identify groups of devices and individual devices.

Currently, only the FAP-S221E, FAP-S223E, and FAP-222E models support this feature.

Use the following syntax to configure BLE profiles, configure BLE report intervals, and assign BLE profiles to WTP profiles.

CLI syntax - Configure BLE profiles

```
config wireless-controller ble-profile
edit <name>
    set comment <comment>
    set advertising {ibeacon | eddystone-uid | eddystone-url}
    set ibeacon-uuid <uuid>
    set major-id <0 - 65535> - (default = 1000)
    set minor-id <0 - 65535> - (default = 1000)
    set eddystone-namespace <10-byte namespace>
    set eddystone-instance <device id>
    set eddystone-url <url>
    set txpower <0 - 12> - (default = 0)
    set beacon-interval <40 - 3500> - (default = 100)
    set ble-scanning {enable | disable} - (default = disable)
next
end
```

Note that `txpower` determines the transmit power level on a scale of 0-12:

0: -21 dBm	1: -18 dBm	2: -15 dBm	3: -12 dBm	4: -9 dBm
5: -6 dBm	6: -3 dBm	7: 0 dBm	8: 1 dBm	9: 2 dBm
10: 3 dBm	11: 4 dBm	12: 5 dBm		

CLI syntax - Configure BLE report intervals

```
config wireless-controller timers
    set ble-scan-report-intv - (default = 30 sec)
end
```

CLI syntax - Assign BLE profiles to WTP profiles

```
config wireless-controller wtp-profile
edit <name>
    set ble-profile <name>
next
end
```

Preventing local bridge traffic from reaching the LAN

The following command can be enabled so that when a client connects to a VAP, and its traffic is not tunneled to the controller, the admin can control whether the client can access the local network.

Note that this entry is only available when `local-standalone-nat` is set to enable.

Syntax:

```
config wireless-controller vap
edit <name>
    set local-lan {allow | deny}
```

```

    next
end

```

FortiAP-S bridge mode security profiles

If you have enabled bridge mode for a managed FortiAP-S, you can add a UTM profile to the wireless controller configuration that allows you to apply the following security profile features to all traffic accepted by the managed FortiAP-S:

- AntiVirus (including Botnet protection),
- IPS,
- Application control, and
- Web Filtering.

You can use the following CLI command to add a wireless controller UTM profile:

```

config wireless-controller utm-profile
  edit <name>
    set comment "Default configuration for offloading WiFi traffic."
    set ips-sensor "wifi-default"
    set application-list "wifi-default"
    set antivirus-profile "wifi-default"
    set webfilter-profile "wifi-default"
    set firewall-profile-protocol-options "wifi-default"
    set firewall-ssl-ssh-profile "wifi-default"
  next
end

```

You can use the following CLI command to add a wireless controller UTM profile to a wireless SSID (virtual access point) configuration:

```

config wireless-controller vap
  edit <name>
    set utm-profile
  end
end

```

DHCP snooping and option 82 (circuit-id) options for wireless access points

New commands are available to enable or disable (by default) DHCP 82 option insertion for wireless access points. DHCP snooping is used to prevent rogue DHCP servers from offering IP addresses to DHCP clients.

Syntax

```

config wireless-controller vap
  edit wifi
    set dhcp-option82-insertion {enable | disable}
    set dhcp-option82-circuit-id-insertion {style-1 | style-2 | disable}
    set dhcp-option82-remote-id-insertion {style-1 | disable}
  next
end

```

Wireless network monitoring

You can monitor both your wireless clients and other wireless networks that are available in your coverage area.

Monitoring wireless clients

To view connected clients on a FortiWiFi unit

1. Go to **Monitor > Client Monitor**.

The following information is displayed:

SSID	The SSID that the client connected to.
FortiAP	The serial number of the FortiAP unit to which the client connected.
User	User name
IP	The IP address assigned to the wireless client.
Device	
Auth	The type of authentication used.
Channel	WiFi radio channel in use.
Bandwidth Tx/Rx	Client received and transmitted bandwidth, in Kbps.
Signal Strength / Noise	The signal-to-noise ratio in deciBels calculated from signal strength and noise level.
Signal Strength	
Association Time	How long the client has been connected to this access point.

Results can be filtered. Select the filter icon on the column you want to filter. Enter the values to include or select NOT if you want to exclude the specified values.

Monitoring rogue APs

The access point radio equipment can scan for other available access points, either as a dedicated monitor or in idle periods during AP operation.

Discovered access points are listed in **Monitor > Rogue AP Monitor**. You can then mark them as either Accepted or Rogue access points. This designation helps you to track access points. It does not affect anyone's ability to use these access points.

It is also possible to suppress rogue APs. See [Monitoring rogue APs on page 1145](#).

On-wire rogue AP detection technique

Other APs that are available in the same area as your own APs are not necessarily rogues. A neighboring AP that has no connection to your network might cause interference, but it is not a security threat. A rogue AP is an unauthorized AP connected to your wired network. This can enable unauthorized access. When rogue AP detection is enabled, the **On-wire** column in the **Rogue AP Monitor** list shows a green up-arrow on detected rogues.

Rogue AP monitoring of WiFi client traffic builds a table of WiFi clients and the Access Points that they are communicating through. The FortiGate unit also builds a table of MAC addresses that it sees on the LAN. The FortiGate unit's on-wire correlation engine constantly compares the MAC addresses seen on the LAN to the MAC addresses seen on the WiFi network.

There are two methods of Rogue AP on-wire detection operating simultaneously: Exact MAC address match and MAC adjacency.

Exact MAC address match

If the same MAC address is seen on the LAN and on the WiFi network, this means that the wireless client is connected to the LAN. If the AP that the client is using is not authorized in the FortiGate unit configuration, that AP is deemed an 'on-wire' rogue. This scheme works for non-NAT rogue APs.

MAC adjacency

If an access point is also a router, it applies NAT to WiFi packets. This can make rogue detection more difficult. However, an AP's WiFi interface MAC address is usually in the same range as its wired MAC address. So, the MAC adjacency rogue detection method matches LAN and WiFi network MAC addresses that are within a defined numerical distance of each other. By default, the MAC adjacency value is 7. If the AP for these matching MAC addresses is not authorized in the FortiGate unit configuration, that AP is deemed an 'on-wire' rogue.

Limitations

On-wire rogue detection has some limitations. There must be at least one WiFi client connected to the suspect AP and continuously sending traffic. If the suspect AP is a router, its WiFi MAC address must be very similar to its Ethernet port MAC address.

Logging

Information about detected rogue APs is logged and uploaded to your FortiAnalyzer unit, if you have one. By default, rogue APs generate an alert level log, unknown APs generate a warning level log. This log information can help you with PCI-DSS compliance requirements.

Rogue AP scanning as a background activity

Each WiFi radio can perform monitoring of radio channels in its operating band while acting as an AP. It does this by briefly switching from AP to monitoring mode. By default, a scan period starts every 300 seconds. Each second a different channel is monitored for 20ms until all channels have been checked.

During heavy AP traffic, it is possible for Spectrum Analysis background scanning to cause lost packets when the radio switches to monitoring. To reduce the probability of lost packets, you can set the CLI `ap-bgscan-idle` field to delay the switch to monitoring until the AP has been idle for a specified period. This means that heavy AP traffic may slow background scanning.

The following CLI example configures default background rogue scanning operation except that it sets `ap-bgscan-idle` to require 100ms of AP inactivity before scanning the next channel.

```
config wireless-controller wtp-profile
  edit ourprofile
    config radio-1
      set wids-profile ourwidsprofile
      set spectrum-analysis enable
    end
  end
config wireless-controller wids-profile
  edit ourwidsprofile
    set ap-scan enable
    set rogue-scan enable
    set ap-bgscan-period 300
    set ap-bgscan-intv 1
    set ap-bgscan-duration 20
    set ap-bgscan-idle 100
  end
```

Configuring rogue scanning

All APs using the same FortiAP Profile share the same rogue scanning settings, unless override is configured.

To enable rogue AP scanning with on-wire detection - web-based manager

1. Go to **WiFi & Switch Controller > WIDS Profiles**.
On some models, the menu is **WiFi & Switch Controller**.
2. Select an existing WIDS Profile and edit it, or select **Create New**.
3. Make sure that **Enable Rogue AP Detection** is selected.
4. Select **Enable On-Wire Rogue AP Detection**.
5. Optionally, enable **Auto Suppress Rogue APs in Foreground Scan**.
6. Select **OK**.

To enable the rogue AP scanning feature in a custom AP profile - CLI

```
config wireless-controller wids-profile
  edit FAP220B-default
    set ap-scan enable
    set rogue-scan enable
  end
```

Exempting an AP from rogue scanning

By default, if Rogue AP Detection is enabled, it is enabled on all managed FortiAP units. Optionally, you can exempt an AP from scanning. You should be careful about doing this if your organization must perform scanning to meet PCI-DSS requirements.

To exempt an AP from rogue scanning

1. Go to **WiFi & Switch Controller > WIDS Profiles**.
2. Create a new WIDS profile and disable **Rogue AP detection**.

3. Go to **WiFi & Switch Controller > FortiAP Profiles** and edit the profile you wish to exempt from rogue scanning.
4. Assign the WIDS profile created in step 2.

MAC adjacency

You can adjust the maximum WiFi to Ethernet MAC difference used when determining whether an suspect AP is a rogue.

To adjust MAC adjacency

For example, to change the adjacency to 8, enter

```
config wireless-controller global
  set rogue-scan-mac-adjacency 8
end
```

Using the Rogue AP Monitor

Go to **Monitor > Rogue AP Monitor** to view the list of other wireless access points that are receivable at your location.

Information Columns

Actual columns displayed depends on **Column Settings**.

State	 Rogue AP — Use this status for unauthorized APs that On-wire status indicates are attached to your wired networks.
	 Accepted AP — Use this status for APs that are an authorized part of your network or are neighboring APs that are not a security threat. To see accepted APs in the list, select Show Accepted .
	 Unclassified — This is the initial status of a discovered AP. You can change an AP back to unclassified if you have mistakenly marked it as Rogue or Accepted.
Online Status	 Active AP
	 Inactive AP
	 Active ad-hoc WiFi device
	 Inactive ad-hoc WiFi device
SSID	The wireless service set identifier (SSID) or network name for the wireless interface.
Security Type	The type of security currently being used.
Channel	The wireless radio channel that the access point uses.
MAC Address	The MAC address of the Wireless interface.
Vendor Info	The name of the vendor.
Signal Strength	The relative signal strength of the AP. Mouse over the symbol to view the signal-to-noise ratio.
Detected By	The name or serial number of the AP unit that detected the signal.
On-wire	A green up-arrow indicates a suspected rogue, based on the on-wire detection technique. A red down-arrow indicates AP is not a suspected rogue.
First Seen	How long ago this AP was first detected.

Last Seen	How long ago this AP was last detected.
Rate	Data rate in bps.

To change the Online Status of an AP, right-click it and select **Mark Accepted** or **Mark Rogue**.

Suppressing rogue APs

In addition to monitoring rogue APs, you can actively prevent your users from connecting to them. When suppression is activated against an AP, the FortiGate WiFi controller sends deauthentication messages to the rogue AP's clients, posing as the rogue AP, and also sends deauthentication messages to the rogue AP, posing as its clients. This is done using the monitoring radio.

Before enabling this feature, verify that operation of Rogue Suppression is compliant with the applicable laws and regulations of your region.

To enable rogue AP suppression, you must enable monitoring of rogue APs with the on-wire detection technique. See "[Monitoring rogue APs](#)". The monitoring radio must be in the Dedicated Monitor mode.

To activate AP suppression against a rogue AP

1. Go to **Monitor > Rogue AP Monitor**.
2. When you see an AP listed that is a rogue detected "on-wire", select it and then select **Mark > Mark Rogue**.
3. To suppress an AP that is marked as a rogue, select it and then select **Suppress AP**.

To deactivate AP suppression

1. Go to **Monitor > Rogue AP Monitor**.
2. Select the suppressed rogue AP and then select **Suppress AP > Unsuppress AP**.

Monitoring wireless network health

To view the wireless health dashboard, go to **Monitor > WiFi Health Monitor**.

The wireless health dashboard provides a comprehensive view of the health of your network's wireless infrastructure. The dashboard includes widgets to display:

- **AP Status**
Active, Down or missing, up for over 24 hours, rebooted in past 24 hours
- **Client Count Over Time**
Viewable for past hour, day, or 30 days
- **Top Client Count Per-AP**
Separate widgets for 2.4GHz and 5GHz bands
- **Top Wireless Interference**
Separate widgets for 2.4GHz and 5GHz bands, requires spectrum analysis to be enabled on the radios

- **Login Failures Information**
- **WiFi Channel Utilization**

Three views allowing users to view top 10-20 Most and Least utilized channels for each AP radio and a third histogram view showing counts for utilization

The list of active clients also shows MAC address entries (similar to the **WiFi Client Monitor** page), making client information easy to view when opening the **Active Client** widget.

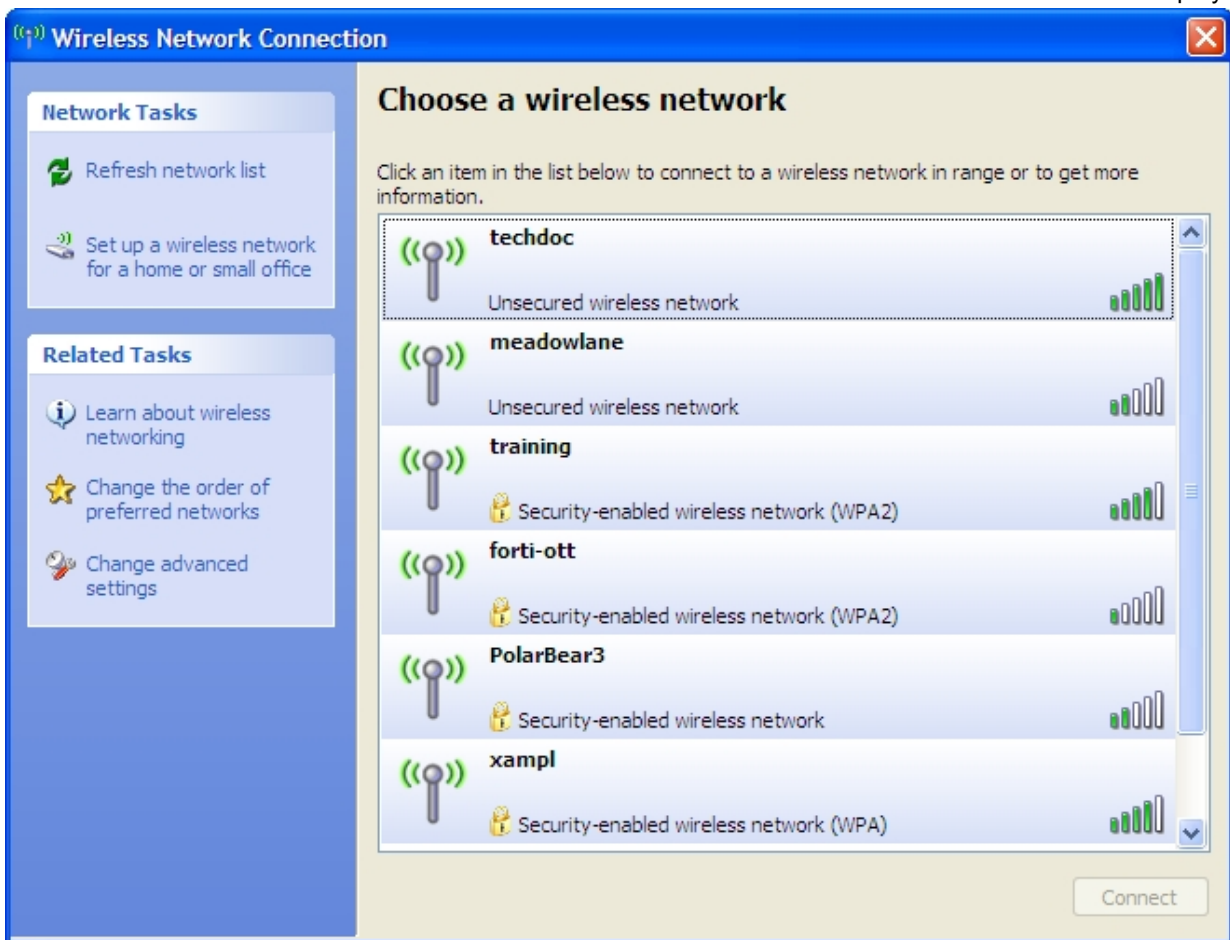

Configuring wireless network clients

This chapter shows how to configure typical wireless network clients to connect to a wireless network with WPA-Enterprise security.

Windows XP client

To configure the WPA-Enterprise network connection

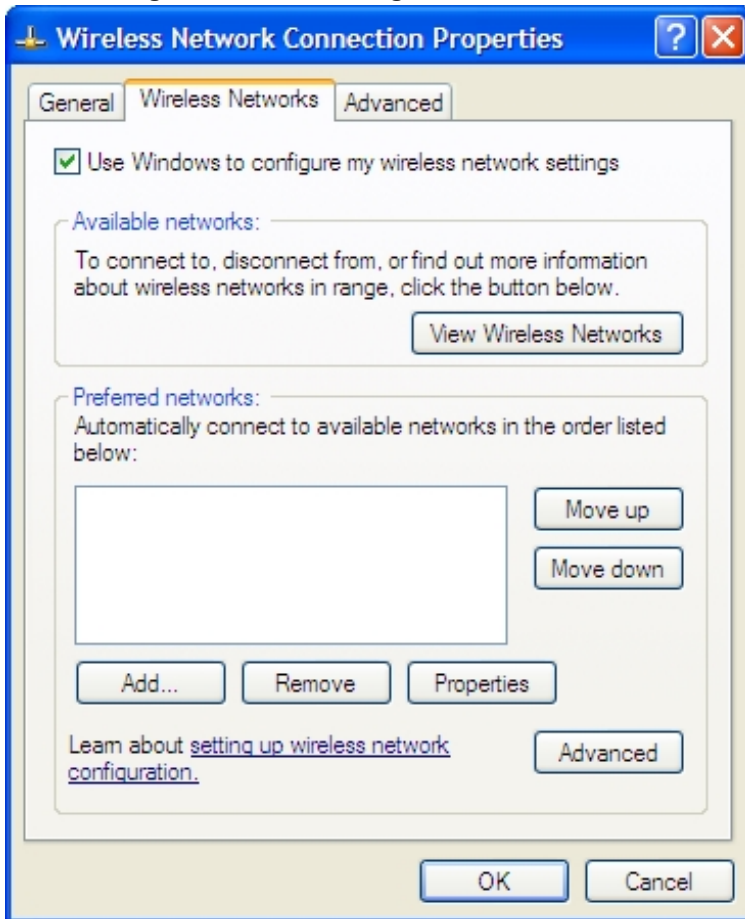

1. In the Windows Start menu, go to **Control Panel > Network Connections > Wireless Network Connection** or select the wireless network icon in the Notification area of the Taskbar. A list of available networks is displayed.

If you are already connected to another wireless network, the Connection Status window displays. Select **View Wireless Networks** on the **General** tab to view the list.

If the network broadcasts its SSID, it is listed. But do not try to connect until you have completed the configuration step below. Because the network doesn't use the Windows XP default security configuration, configure the client's network settings manually before trying to connect.

2. You can configure the WPA-Enterprise network to be accessible from the **View Wireless Networks** window even if it does not broadcast its SSID.
3. Select **Change Advanced Settings** and then select the **Wireless Networks** tab.

Any existing networks that you have already configured are listed in the **Preferred Networks** list.

4. Select **Add** and enter the following information:

Wireless network properties

Association Authentication Connection

Network name (SSID): xample

☐ Connect even if this network is not broadcasting

Wireless network key

This network requires a key for the following:

Network Authentication: WPA2

Data encryption: AES

Network key:

Confirm network key:

Key index (advanced): 1

☐ The key is provided for me automatically

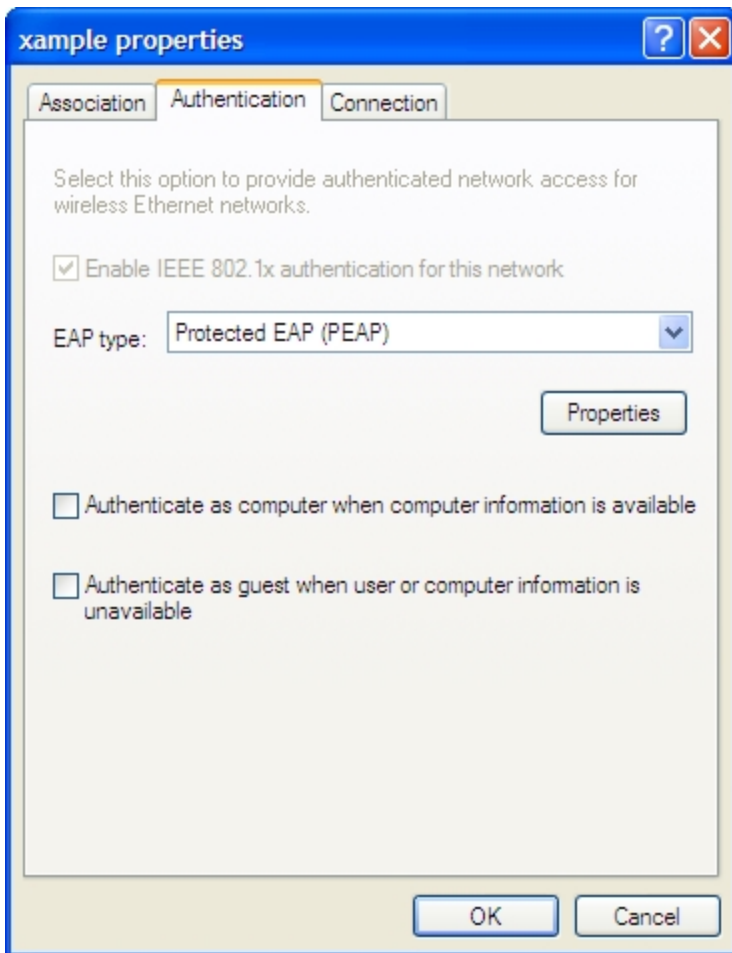

☐ This is a computer-to-computer (ad hoc) network; wireless access points are not used

OK Cancel

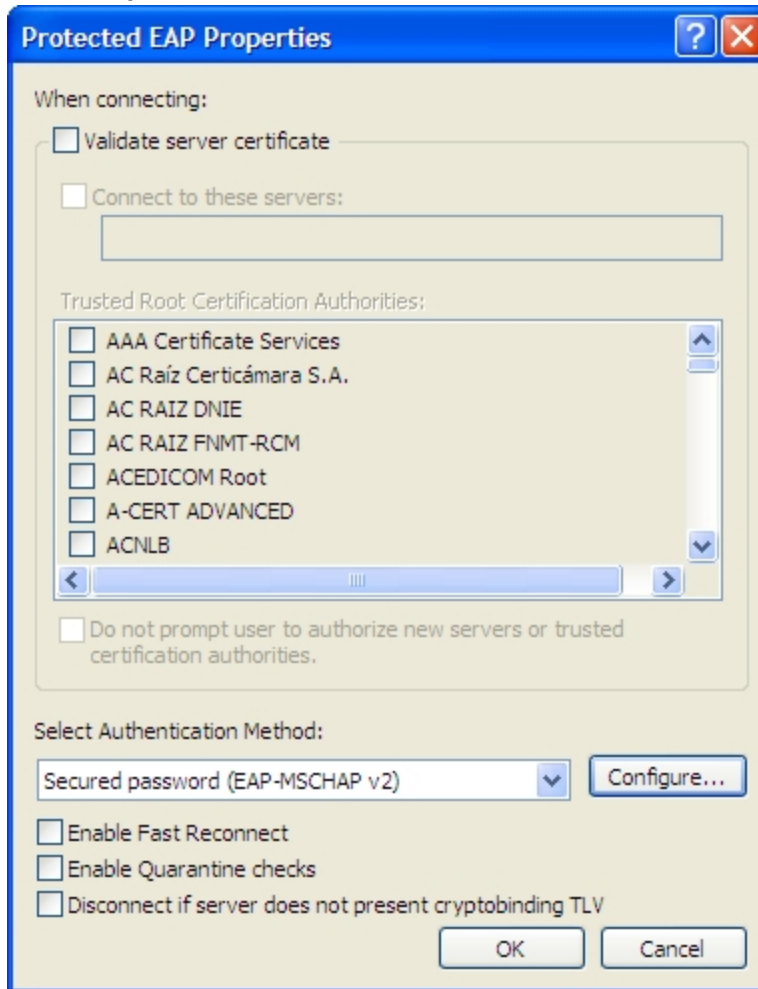

Network Name (SSID)	The SSID for your wireless network
Network Authentication	WPA2
Data Encryption	AES

5. If this wireless network does not broadcast its SSID, select **Connect even if this network is not broadcasting** so that the network will appear in the **View Wireless Networks** list.

6. Select the **Authentication** tab.

7. In **EAP Type**, select **Protected EAP (PEAP)**.
8. Make sure that the other two authentication options are not selected.

9. Select **Properties**.

10. Make sure that **Validate server certificate** is selected.
11. Select the server certificate **Entrust Root Certification Authority**.
12. In **Select Authentication Method**, select **Secured Password (EAP-MSCHAPv2)**.
13. Ensure that the remaining options are not selected.
14. Select **Configure**.

15. If your wireless network credentials are the same as your Windows logon credentials, select **Automatically use my Windows logon name and password**. Otherwise, make sure that this option is not selected.
16. Select **OK**. Repeat until you have closed all of the **Wireless Network Connection Properties** windows.

To connect to the WPA-Enterprise wireless network

1. Select the wireless network icon in the Notification area of the Taskbar.
2. In the **View Wireless Networks** list, select the network you just added and then select **Connect**. You might need to log off of your current wireless network and refresh the list.
3. When the following popup displays, click on it.

4. In the **Enter Credentials** window, enter your wireless network **User name**, **Password**, and **Logon domain** (if applicable). Then, select **OK**.

In future, Windows will automatically send your credentials when you log on to this network.

Windows 7 client

1. In the Windows Start menu, go to **Control Panel > Network and Internet > Network and Sharing Center > Manage Wireless Networks** or select the wireless network icon in the Notification area of the Taskbar. A list of available networks is displayed.

2. Do one of the following:
 - If the wireless network is listed (it broadcasts its SSID), select it from the list.
 - Select **Add > Manually create a network profile**.

3. Enter the following information and select **Next**.

Manually connect to a wireless network

Enter information for the wireless network you want to add

Network name:

Security type:

Encryption type:

Security Key: ☐ Hide characters

☒ Start this connection automatically

☒ Connect even if the network is not broadcasting

Warning: If you select this option, your computer's privacy might be at risk.

Network name	Enter the SSID of the wireless network. (Required only if you selected Add.)
Security type	WPA2-Enterprise
Encryption type	AES
Start this connection automatically	Select
Connect even if the network is not broadcasting.	Select

The Wireless Network icon will display a popup requesting that you click to enter credentials for the network. Click on the popup notification.

4. In the **Enter Credentials** window, enter your wireless network **User name**, **Password**, and **Logon domain** (if applicable). Then, select **OK**.
5. Select **Change connection settings**.
6. On the **Connection** tab, select **Connect automatically when this network is in range**.
7. On the **Security** tab, select the Microsoft PEAP authentication method and then select **Settings**.

8. Make sure that **Validate server certificate** is selected.
9. Select the server certificate **Entrust Root Certification Authority**.
10. In **Select Authentication Method**, select **Secured Password (EAP-MSCHAPv2)**.
11. Select **Configure**.

12. If your wireless network credentials are the same as your Windows logon credentials, select **Automatically use my Windows logon name and password**. Otherwise, make sure that this option is not selected.
13. Ensure that the remaining options are not selected.
14. Select **OK**. Repeat until you have closed all of the **Wireless Network Properties** windows.

Mac OS client

To configure network preferences

1. Right-click the **AirPort** icon in the toolbar and select **Open Network Preferences**.
2. Select **Advanced** and then select the **802.1X** tab.

3. If there are no Login Window Profiles in the left column, select the + button and then select **Add Login Window Profile**.
4. Select the Login Window Profile and then make sure that both TTLS and PEAP are selected in **Authentication**.

To configure the WPA-Enterprise network connection

1. Select the **AirPort** icon in the toolbar.
2. Do one of the following:
 - If the network is listed, select the network from the list.
 - Select **Connect to Other Network**.

One of the following windows opens, depending on your selection.

The network "xampl" requires a password.

User Name:

Password:

802.1X:

☒ Remember this network

Enter the name of the network.

Enter the name of the network you want to join, and then enter the password if necessary.

Network Name:

Security:

User Name:

Password:

802.1X:

☒ Remember this network

3. Enter the following information and select **OK** or **Join**:

Network name	Enter the SSID of your wireless network. (Other network only)
Wireless Security	WPA Enterprise
802.1X	Automatic
Username Password	Enter your logon credentials for the wireless network.
Remember this network	Select.

You are connected to the wireless network.

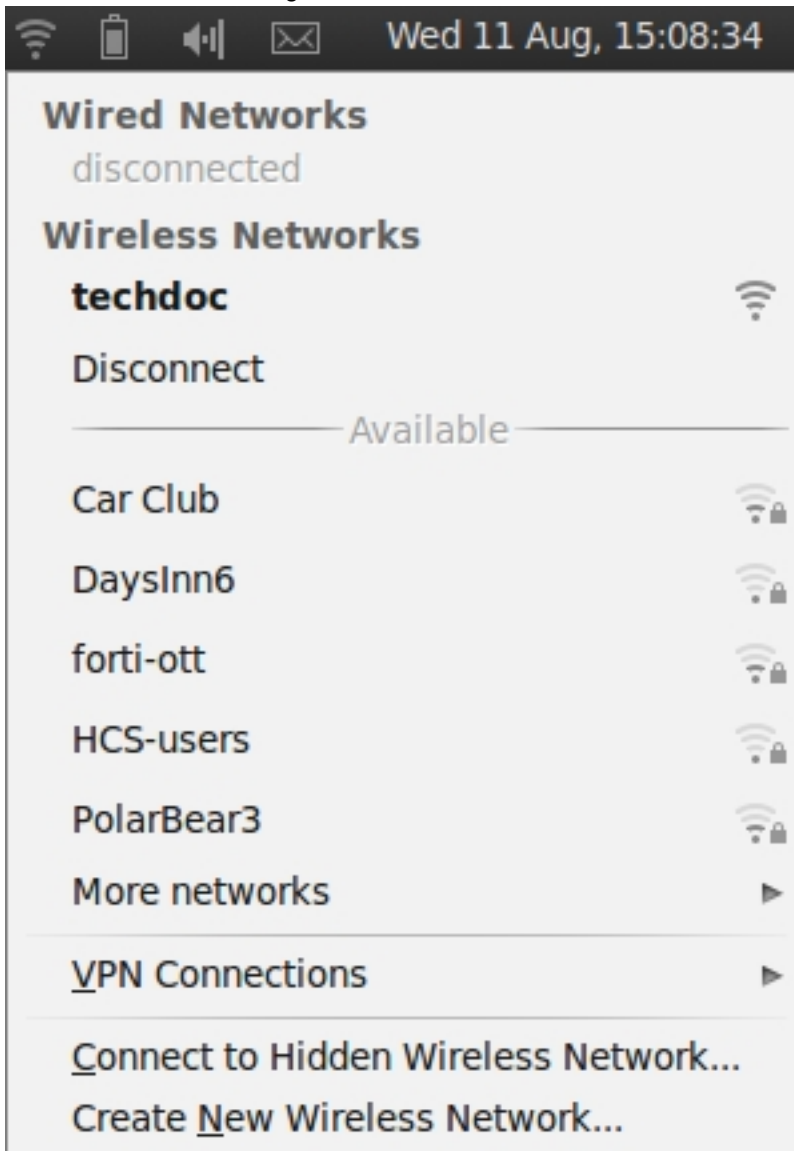

Mac OS supports only PEAP with MSCHAPv2 authentication and therefore can authenticate only to a RADIUS server, not an LDAP or TACACS+ server

Linux client

This example is based on the Ubuntu 10.04 Linux wireless client.

To connect to a WPA-Enterprise network

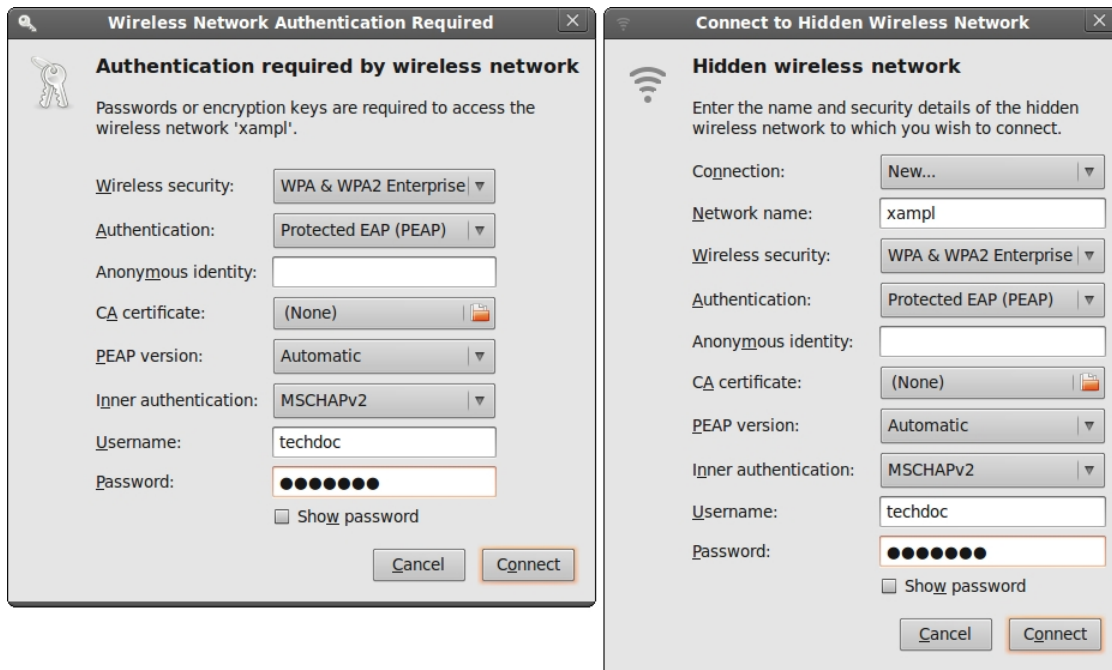

1. Select the Network Manager icon to view the Wireless Networks menu.

Wireless networks that broadcast their SSID are listed in the **Available** section of the menu. If the list is long, it is continued in the **More Networks** submenu.

2. Do one of the following:
 - Select the network from the list (also check **More Networks**).
 - Select **Connect to Hidden Wireless Network**.

One of the following windows opens, depending on your selection.

3. Enter the following information:

Connection	Leave as New . (Hidden network only)
Network name	Enter the SSID of your wireless network. (Hidden network only)
Wireless Security	WPA & WPA2 Enterprise
Authentication	Protected EAP (PEAP) for RADIUS-based authentication Tunneled TLS for TACACS+ or LDAP-based authentication
Anonymous identity	This is not required.
CA Certificate	If you want to validate the AP's certificate, select the Entrust Root Certification Authority root certificate. The default location for the certificate is /usr/share/ca-certificates/mozilla/.
PEAP version	Automatic (applies only to PEAP)
Inner authentication	MSCHAPv2 for RADIUS-based authentication PAP or CHAP for TACACS+ or LDAP-based authentication
Username Password	Enter your logon credentials for the wireless network.

4. If you did not select a CA Certificate above, you are asked to do so. Select Ignore.

5. Select **Connect**. You are connected to the wireless network.

To connect to a WPA-Enterprise network

1. Select the Network Manager icon to view the Wireless Networks menu.
2. Select the network from the list (also check **More Networks**).
If your network is not listed (but was configured), select **Connect to Hidden Wireless Network**, select your network from the Connection drop-down list, and then select **Connect**.

Troubleshooting

Using tools provided in your operating system, you can find the source of common wireless networking problems.

Checking that client received IP address and DNS server information

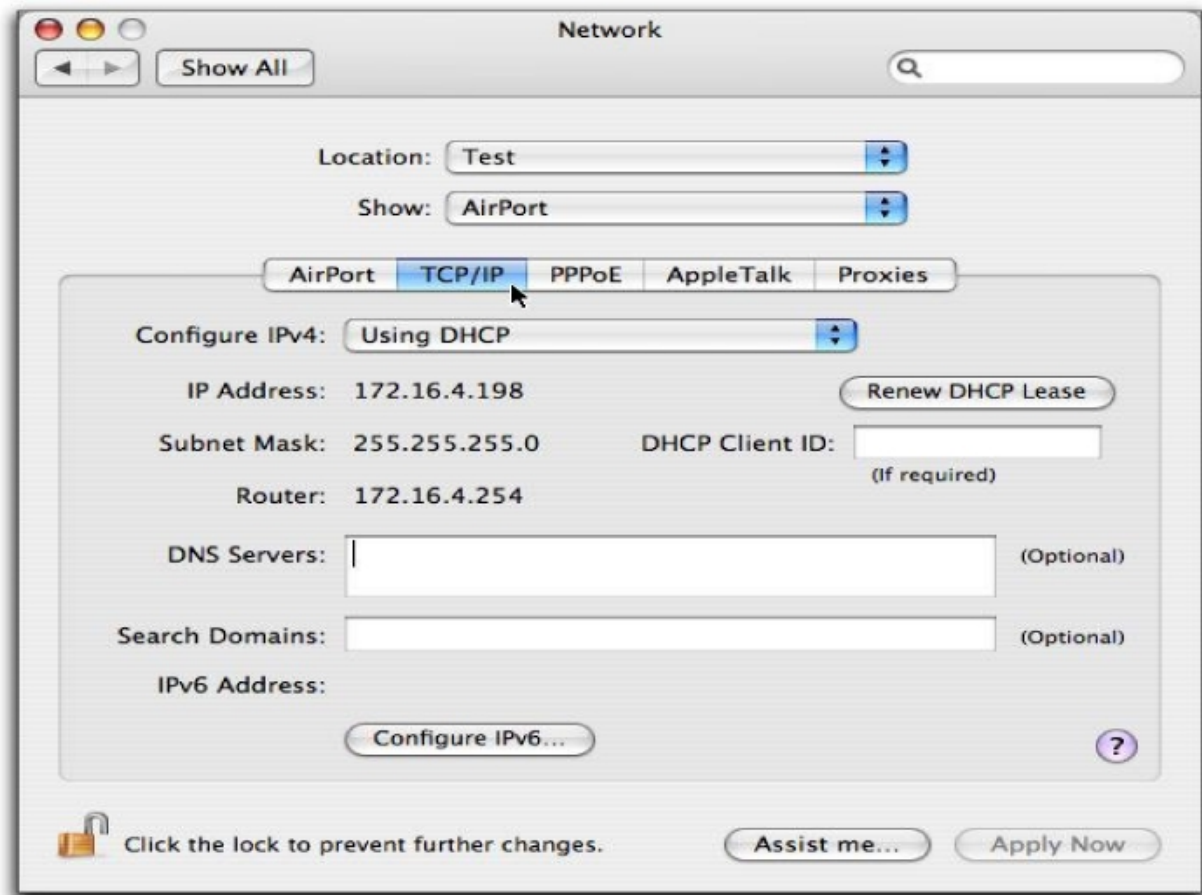

Windows XP

1. Double-click the network icon in the taskbar to display the **Wireless Network Connection Status** window. Check that the correct network is listed in the **Connection** section.
2. Select the **Support** tab.
Check that the **Address Type** is **Assigned by DHCP**. Check that the **IP Address**, **Subnet Mask**, and **Default Gateway** values are valid.
3. Select **Details** to view the DNS server addresses.
The listed address should be the DNS serves that were assigned to the WAP. Usually a wireless network that provides access to the private LAN is assigned the same DNS servers as the wired private LAN. A wireless network that provides guest or customer users access to the Internet is usually assigned public DNS servers.
4. If any of the addresses are missing, select **Repair**.
If the repair procedure doesn't correct the problem, check your network settings.

Mac OS

1. From the Apple menu, open **System Preferences > Network**.
2. Select **AirPort** and then select **Configure**.

- On the **Network** page, select the **TCP/IP** tab.

- If there is no IP address or the IP address starts with 169, select **Renew DHCP Lease**.
- To check DNS server addresses, open a terminal window and enter the following command:

```
cat /etc/resolv.conf
```

Check the listed nameserver addresses. A network for employees should use the wired private LAN DNS server. A network for guests should specify a public DNS server.

Linux

This example is based on the Ubuntu 10.04 Linux wireless client.

1. Right-click the Network Manager icon and select **Connection Information**.

2. Check the IP address, and DNS settings. If they are incorrect, check your network settings.

Wireless network examples

This chapter provides an example wireless network configuration.

Basic wireless network

This example uses automatic configuration to set up a basic wireless network.

To configure this wireless network, you must:

- Configure authentication for wireless users
- Configure the SSID (WiFi network interface)
- Add the SSID to the FortiAP Profile
- Configure the firewall policy
- Configure and connect FortiAP units

Configuring authentication for wireless users

You need to configure user accounts and add the users to a user group. This example shows only one account, but multiple accounts can be added as user group members.

To configure a WiFi user - web-based manager

1. Go to **User & Device > User Definition** and select **Create New**.
2. Select **Local User** and then click **Next**.
3. Enter a **User Name** and **Password** and then click **Next**.
4. Click **Next**.
5. Make sure that **Enable** is selected and then click **Create**.

To configure the WiFi user group - web-based manager

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	wlan_users
Type	Firewall
Members	Add users.

To configure a WiFi user and the WiFi user group - CLI

```
config user user
  edit "user01"
    set type password
    set passwd "asdf12ghjk"
  end
config user group
```

```
edit "wlan_users"
  set member "user01"
end
```

Configuring the SSID

First, establish the SSID (network interface) for the network. This is independent of the number of physical access points that will be deployed. The network assigns IP addresses using DHCP.

To configure the SSID - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and select **Create New > SSID**.
2. Enter the following information and select **OK**:

Interface Name	example_wifi_if
Traffic Mode	Tunnel to Wireless Controller
IP/Network Mask	10.10.110.1/24
Administrative Access	Ping (to assist with testing)
DHCP Server	Enable
Address Range	10.10.110.2 - 10.10.110.199
Netmask	255.255.255.0
Default Gateway	Same As Interface IP
DNS Server	Same as System DNS
SSID	example_wifi
Security Mode	WPA2 Enterprise
Authentication	Local, select wlan_users user group.
Leave other settings at their default values.	

To configure the SSID - CLI

```
config wireless-controller vap
  edit example_wifi_if
    set ssid "example_wifi"
    set broadcast-ssid enable
    set security wpa-enterprise
    set auth usergroup
    set usergroup wlan_users
    set schedule always
  end
config system interface
  edit example_wifi_if
    set ip 10.10.110.1 255.255.255.0
  end
config system dhcp server
```

```

edit 0
    set default-gateway 10.10.110.1
    set dns-service default
    set interface "example_wifi_if"
    config ip-range
        edit 1
            set end-ip 10.10.110.199
            set start-ip 10.10.110.2
        end
    set netmask 255.255.255.0
end

```

Adding the SSID to the FortiAP Profile

The radio portion of the FortiAP configuration is contained in the FortiAP Profile. By default, there is a profile for each platform (FortiAP model). You can create additional profiles if needed. The SSID needs to be specified in the profile.

To add the SSID to the FortiAP Profile - web-based manager

1. Go to **WiFi & Switch Controller > FortiAP Profiles** and edit the profile for your model of FortiAP unit.
2. In **Radio 1** and **Radio 2**, add example_wifi in **SSID**.
3. Select **OK**.

Configuring security policies

A security policy is needed to enable WiFi users to access the Internet on port1. First you create firewall address for the WiFi network, then you create the example_wifi to port1 policy.

To create a firewall address for WiFi users - web-based manager

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New > Address**, enter the following information and select **OK**.

Name	wlan_user_net
Type	IP/Netmask
Subnet / IP Range	10.10.110.0/24
Interface	example_wifi_if
Show in Address List	Enabled

To create a firewall address for WiFi users - CLI

```

config firewall address
    edit "wlan_user_net"
        set associated-interface "example_wifi_if"
        set subnet 10.10.110.0 255.255.255.0
    end

```

To create a security policy for WiFi users - web-based manager

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**:

Incoming Interface	example_wifi_if
Source Address	wlan_user_net
Outgoing Interface	port1
Destination Address	All
Schedule	always
Service	ALL
Action	ACCEPT
NAT	ON. Select Use Destination Interface Address (default).
Leave other settings at their default values.	

To create a firewall policy for WiFi users - CLI

```
config firewall policy
  edit 0
    set srcintf "example_wifi"
    set dstintf "port1"
    set srcaddr "wlan_user_net"
    set dstaddr "all"
    set schedule always
    set service ALL
    set action accept
    set nat enable
  end
```

Connecting the FortiAP units

You need to connect each FortiAP unit to the FortiGate unit, wait for it to be recognized, and then assign it to the AP Profile. But first, you must configure the interface to which the FortiAP units connect and the DHCP server that assigns their IP addresses.

In this example, the FortiAP units connect to port 3 and are controlled through IP addresses on the 192.168.8.0/24 network.

To configure the interface for the AP unit - web-based manager

1. Go to **Network > Interfaces** and edit the port3 interface.
2. Set the **Addressing mode** to **Dedicated to Extension Device** and set the **IP/Network Mask** to 192.168.8.1/255.255.255.0.
3. Select **OK**.

This procedure automatically configures a DHCP server for the AP units.

To configure the interface for the AP unit - CLI

```
config system interface
edit port3
set mode static
set ip 192.168.8.1 255.255.255.0
end
```

To configure the DHCP server for AP units - CLI

```
config system dhcp server
edit 0
set interface port3
config exclude-range
edit 1
set end-ip 192.168.8.1
set start-ip 192.168.8.1
end
config ip-range
edit 1
set end-ip 192.168.8.254
set start-ip 192.168.8.2
end
set netmask 255.255.255.0
set vci-match enable
set vci-string "FortiAP"
end
```

To connect a FortiAP unit - web-based manager

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
2. Connect the FortiAP unit to port 3.
3. Periodically select **Refresh** while waiting for the FortiAP unit to be listed.
Recognition of the FortiAP unit can take up to two minutes.
If FortiAP units are connected but cannot be recognized, try disabling VCI-Match in the DHCP server settings.
4. When the FortiAP unit is listed, select the entry to edit it.
The **Edit Managed Access Point** window opens.
5. In **State**, select **Authorize**.
6. In **FortiAP Profile**, select the default profile for the FortiAP model.
7. Select **OK**.
8. Repeat Steps 2 through 8 for each FortiAP unit.

To connect a FortiAP unit - CLI

1. Connect the FortiAP unit to port 3.
2. Enter

```
config wireless-controller wtp
```

3. Wait 30 seconds, then enter `get`.

Retry the `get` command every 15 seconds or so until the unit is listed, like this:

```
== [ FAP22B3U10600118 ]
wtp-id: FAP22B3U10600118
```

4. Edit the discovered FortiAP unit like this:

```
edit FAP22B3U10600118
    set admin enable
end
```

5. Repeat Steps 2 through 4 for each FortiAP unit.

A more complex example

This example creates multiple networks and uses custom AP profiles.

Scenario

In this example, Example Co. provides two wireless networks, one for its employees and the other for customers or other guests of its business. Guest users have access only to the Internet, not to the company's private network. The equipment for these WiFi networks consists of FortiAP-220B units controlled by a FortiGate unit.

The employee network operates in 802.11n mode on both the 2.4GHz and 5GHz bands. Client IP addresses are in the 10.10.120.0/24 subnet, with 10.10.120.1 the IP address of the WAP. The guest network also operates in 802.11n mode, but only on the 2.4GHz band. Client IP addresses are on the 10.10.115.0/24 subnet, with 10.10.115.1 the IP address of the WAP.

On FortiAP-220B units, the 802.11n mode also supports 802.11g and 802.11b clients on the 2.4GHz band and 802.11a clients on the 5GHz band.

The guest network WAP broadcasts its SSID, the employee network WAP does not.

The employees network uses WPA-Enterprise authentication through a FortiGate user group. The guest network features a captive portal. When a guest first tries to connect to the Internet, a login page requests logon credentials. Guests use numbered guest accounts authenticated by RADIUS. The captive portal for the guests includes a disclaimer page.

In this example, the FortiAP units connect to port 3 and are assigned addresses on the 192.168.8.0/24 subnet.

Configuration

To configure these wireless networks, you must:

- Configure authentication for wireless users
- Configure the SSIDs (network interfaces)
- Configure the AP profile
- Configure the WiFi LAN interface and a DHCP server
- Configure firewall policies

Configuring authentication for employee wireless users

Employees have user accounts on the FortiGate unit. This example shows creation of one user account, but you can create multiple accounts and add them as members to the user group.

To configure a WiFi user - web-based manager

1. Go to **User & Device > User Definition** and select **Create New**.
2. Select **Local User** and then click **Next**.

3. Enter a **User Name** and **Password** and then click **Next**.
4. Click **Next**.
5. Make sure that **Enable** is selected and then click **Create**.

To configure the user group for employee access - web-based manager

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	employee-group
Type	Firewall
Members	Add users.

To configure a WiFi user and the user group for employee access - CLI

```
config user user
  edit "user01"
    set type password
    set passwd "asdf12ghjk"
  end
config user group
  edit "employee-group"
    set member "user01"
  end
```

The user authentication setup will be complete when you select the employee-group in the SSID configuration.

Configuring authentication for guest wireless users

Guests are assigned temporary user accounts created on a RADIUS server. The RADIUS server stores each user's group name in the Fortinet-Group-Name attribute. Wireless users are in the group named "wireless".

The FortiGate unit must be configured to access the RADIUS server.

To configure the FortiGate unit to access the guest RADIUS server - web-based manager

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter the following information and select OK:

Name	guestRADIUS
Primary Server IP/Name	10.11.102.100
Primary Server Secret	grikfwpdfg
Secondary Server IP/Name	Optional
Secondary Server Secret	Optional
Authentication Scheme	Use default, unless server requires otherwise.
Leave other settings at their default values.	

To configure the FortiGate unit to access the guest RADIUS server - CLI

```
config user radius
  edit guestRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret grikfwpfdg
  end
```

To configure the user group for guest access - web-based manager

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	guest-group
Type	Firewall
Members	Leave empty.

3. Select **Create new**.
4. Enter:

Remote Server	Select guestRADIUS .
Groups	Select wireless

5. Select **OK**.

To configure the user group for guest access - CLI

```
config user group
  edit "guest-group"
    set member "guestRADIUS"
    config match
      edit 0
        set server-name "guestRADIUS"
        set group-name "wireless"
      end
    end
  end
```

The user authentication setup will be complete when you select the guest-group user group in the SSID configuration.

Configuring the SSIDs

First, establish the SSIDs (network interfaces) for the employee and guest networks. This is independent of the number of physical access points that will be deployed. Both networks assign IP addresses using DHCP.

To configure the employee SSID - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and select **Create New > SSID**.
2. Enter the following information and select **OK**:

Interface Name	example_inc
Traffic Mode	Tunnel to Wireless Controller
IP/Netmask	10.10.120.1/24
Administrative Access	Ping (to assist with testing)
Enable DHCP	Enable
Address Range	10.10.120.2 - 10.10.120.199
Netmask	255.255.255.0
Default Gateway	Same As Interface IP
DNS Server	Same as System DNS
SSID	example_inc
Security Mode	WPA/WPA2-Enterprise
Authentication	Select Local , then select employee-group .
Leave other settings at their default values.	

To configure the employee SSID - CLI

```

config wireless-controller vap
  edit example_inc
    set ssid "example_inc"
    set security wpa-enterprise
    set auth usergroup
    set usergroup employee-group
    set schedule always
  end
config system interface
  edit example_inc
    set ip 10.10.120.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set default-gateway 10.10.120.1
    set dns-service default
    set interface example_inc
    config ip-range
      edit 1
        set end-ip 10.10.120.199
        set start-ip 10.10.120.2
      end
    set lease-time 7200
    set netmask 255.255.255.0
  end
end

```

To configure the example_guest SSID - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and select **Create New**.
2. Enter the following information and select **OK**:

Name	example_guest
IP/Netmask	10.10.115.1/24
Administrative Access	Ping (to assist with testing)
Enable DHCP	Enable
Address Range	10.10.115.2 - 10.10.115.50
Netmask	255.255.255.0
Default Gateway	Same as Interface IP
DNS Server	Same as System DNS
SSID	example_guest
Security Mode	Captive Portal
Portal Type	Authentication
Authentication Portal	Local
User Groups	Select guest-group
Leave other settings at their default values.	

To configure the example_guest SSID - CLI

```
config wireless-controller vap
  edit example_guest
    set ssid "example_guest"
    set security captive-portal
    set selected-usergroups guest-group
    set schedule always
  end
config system interface
  edit example_guest
    set ip 10.10.115.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set default-gateway 10.10.115.1
    set dns-service default
    set interface "example_guest"
    config ip-range
      edit 1
        set end-ip 10.10.115.50
        set start-ip 10.10.115.2
      end
    set lease-time 7200
```

```

set netmask 255.255.255.0
end

```

Configuring the FortiAP profile

The FortiAP Profile defines the radio settings for the networks. The profile provides access to both Radio 1 (2.4GHz) and Radio 2 (5GHz) for the employee virtual AP, but provides access only to Radio 1 for the guest virtual AP.

To configure the FortiAP Profile - web-based manager

1. Go to **WiFi & Switch Controller > FortiAP Profiles** and select **Create New**.
2. Enter the following information and select **OK**:

Name	example_AP
Platform	FAP220B
Radio 1	
Mode	Access Point
Band	802.11n
Channel	Select 1, 6, and 11.
Tx Power	100%
SSID	Select SSIDs and select example_inc and example_guest .
Radio 2	
Mode	Access Point
Band	802.11n_5G
Channel	Select all.
Tx Power	100%
SSID	Select SSIDs and select example_inc .

To configure the AP Profile - CLI

```

config wireless-controller wtp-profile
  edit "example_AP"
    config platform
      set type 220B
    end
    config radio-1
      set ap-bgscan enable
      set band 802.11n
      set channel "1" "6" "11"
      set vaps "example_inc" "example_guest"
    end
    config radio-2

```

```
set ap-bgscan enable
set band 802.11n-5G
set channel "36" "40" "44" "48" "149" "153" "157" "161" "165"
set vaps "example_inc"
end
```

Configuring firewall policies

Identity-based firewall policies are needed to enable the WLAN users to access the Internet on Port1. First you create firewall addresses for employee and guest users, then you create the firewall policies.

To create firewall addresses for employee and guest WiFi users

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, enter the following information and select **OK**.

Address Name	employee-wifi-net
Type	Subnet / IP Range
Subnet / IP Range	10.10.120.0/24
Interface	example_inc

3. Select **Create New**, enter the following information and select **OK**.

Address Name	guest-wifi-net
Type	Subnet / IP Range
Subnet / IP Range	10.10.115.0/24
Interface	example_guest

To create firewall policies for employee WiFi users - web-based manager

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**:

Incoming Interface	example_inc
Source Address	employee-wifi-net
Outgoing Interface	port1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enable NAT

3. Optionally, select security profile for wireless users.
4. Select **OK**.
5. Repeat steps 1 through 4 but select Internal as the Destination Interface/Zone to provides access to the ExampleCo private network.

To create firewall policies for employee WiFi users - CLI

```
config firewall policy
  edit 0
    set srcintf "employee_inc"
    set dstintf "port1"
    set srcaddr "employee-wifi-net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
    set schedule "always"
    set service "ANY"
  next
  edit 0
    set srcintf "employee_inc"
    set dstintf "internal"
    set srcaddr "employee-wifi-net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
    set schedule "always"
    set service "ANY"
  end
```

To create a firewall policy for guest WiFi users - web-based manager

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**:

Incoming Interface	example_guest
Source Address	guest-wifi-net
Outgoing Interface	port1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enable NAT

3. Optionally, select **UTM** and set up UTM features for wireless users.
4. Select **OK**.

To create a firewall policy for guest WiFi users - CLI

```
config firewall policy
  edit 0
    set srcintf "example_guest"
    set dstintf "port1"
    set srcaddr "guest-wifi-net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
  end
```

Connecting the FortiAP units

You need to connect each FortiAP-220A unit to the FortiGate unit, wait for it to be recognized, and then assign it to the AP Profile. But first, you must configure the interface to which the FortiAP units connect and the DHCP server that assigns their IP addresses.

In this example, the FortiAP units connect to port 3 and are controlled through IP addresses on the 192.168.8.0/24 network.

To configure the interface for the AP unit - web-based manager

1. Go to **Network > Interfaces** and edit the port3 interface.
2. Set the **Addressing mode** to **Dedicated to Extension Device** and set the **IP/Netmask** to 192.168.8.1/255.255.255.0.
This step automatically configures a DHCP server for the AP units.
3. Select **OK**.

To configure the interface for the AP unit - CLI

```
config system interface
  edit port3
    set mode static
    set ip 192.168.8.1 255.255.255.0
  end
```

To configure the DHCP server for AP units - CLI

```
config system dhcp server
  edit 0
    set interface port3
    config ip-range
      edit 1
        set end-ip 192.168.8.9
        set start-ip 192.168.8.2
      end
    set netmask 255.255.255.0
    set vci-match enable
    set vci-string "FortiAP"
```

end

To connect a FortiAP-220A unit - web-based manager

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
2. Connect the FortiAP unit to port 3.
3. Periodically select **Refresh** while waiting for the FortiAP unit to be listed.
Recognition of the FortiAP unit can take up to two minutes.
If there is persistent difficulty recognizing FortiAP units, try disabling VCI-Match in the DHCP server settings.
4. When the FortiAP unit is listed, select the entry to edit it.
The **Edit Managed Access Point** window opens.
5. In **State**, select **Authorize**.
6. In the **AP Profile**, select **[Change]** and then select the **example_AP** profile.
7. Select **OK**.
8. Repeat Steps 2 through 8 for each FortiAP unit.

To connect a FortiAP-220A unit - CLI

1. Connect the FortiAP unit to port 3.
2. Enter:

```
config wireless-controller wtp
```
3. Wait 30 seconds, then enter `get`.
Retry the `get` command every 15 seconds or so until the unit is listed, like this:

```
== [ FAP22A3U10600118 ]
wtp-id: FAP22A3U10600118
```
4. Edit the discovered FortiAP unit like this:

```
edit FAP22A3U10600118
    set admin enable
    set wtp-profile example_AP
end
```
5. Repeat Steps 2 through 4 for each FortiAP unit.

Managing a FortiAP with FortiCloud

This chapter provides a few FortiCloud-managed FortiAP configuration examples.

You can register for a free FortiCloud account at www.forticloud.com.

For a video tutorial of how to configure and manage a FortiAP-S device from FortiCloud, follow the link below:

- [How to configure and Manage FortiAP-S from FortiCloud](#)

FortiCloud-managed FortiAP WiFi

In this example, you use FortiCloud to configure a single FortiAP-221C, creating a working WiFi network without a FortiGate.

FortiCloud remote management is supported on FortiAP models 221C and 320C.

For this configuration, the FortiAP-221C unit is running version 5.2 firmware. You will create a simple network that uses WPA-Personal authentication.

You can register for a free FortiCloud account at www.forticloud.com.

To create the WiFi network without a FortiGate unit, you must:

- Add your FortiAP to FortiCloud
- Configure the SSID
- Configure the AP platform profile
- Deploy the AP with the profile

Adding your FortiAP to FortiCloud

You need to add the FortiAP unit to your FortiCloud account. This is done through a unique key that can be found under the FortiAP unit.

To add a FortiAP to FortiCloud

1. Connect the FortiAP Ethernet interface to a network that provides access to the Internet.
2. Open a web browser and navigate to the FortiCloud main page and select **+ AP Network**.
3. Enter an **AP Network Name** and **AP Password**. This password is used to locally log in to the AP as the administrator. It will be set to all APs in this AP network.
4. Set the correct **Time Zone** and select **Submit**.

Configuring the SSID

You must establish the SSID (network interface) for the WiFi network.

To configure the SSID

1. Select the FortiAP you just created from the home page. You will then be prompted to add an SSID for the AP Network.
In the interface, this is under **Configure > SSIDs**.

2. In **Access Control**, enter the name of your SSID, set **Authentication** to **WPA2-Personal**, enter the **Pre-shared Key**, and select **Next**.
3. In **Security**, enable security features as required (select from **AntiVirus**, **Intrusion Prevention**, **Block Botnet**, **Web Access**, and **Application Control**) and select **Next**.
4. In **Availability**, make sure to leave **5 GHz** enabled, configure a schedule as required, and select **Next**.
5. Review your SSID in **Preview**, then select **Apply**.

Configuring the AP platform profile

The radio portion of the FortiAP configuration is contained in the FortiAP platform profile. By default, there is a profile for each platform (FortiAP model). The SSID needs to be specified in the profile.

To configure the AP profile

1. Go to **Configure > AP Profile** and edit the AP Profile for your FortiAP model (mouse-over the AP Profile to reveal the **Edit** button).
2. Enable the SSID configured earlier for both **Radio 1** and **Radio 2**, for 5GHz coverage.

Deploying the AP with the platform profile

With the SSID and platform profile configured, you must deploy the AP by entering the FortiCloud key for the FortiAP.

To deploy the AP

1. Go to **Configure > Deploy APs**. Here you will be prompted to enter the FortiCloud key, which can be found on the same label as the FortiAP unit's serial number, and select **Submit**.

If you have a FortiAP model that does *not* include a FortiCloud key, you can still add the device to the network. To learn how, see the [FortiCloud-managed FortiAP WiFi without a key](#) configuration.

2. In **Set Platform Profiles**, select the platform profile you created earlier and select **Next**.
3. Follow the rest of the deployment wizard. Select **Submit** when completed.

You will now be able to connect to the wireless network and browse the Internet. On the FortiCloud website, go to **Monitor > Report** where you can view monitoring information such as **Traffic by Period**, **Client Count by Period**, and more.

FortiCloud-managed FortiAP WiFi without a key

You can manage your FortiAP-based wireless network with FortiCloud even if your FortiAP has no FortiCloud key.

For this example, you will need to have already pre-configured your FortiAP unit with your FortiCloud account credentials. For more information on how to do this, or if your FortiAP has a FortiCloud key (on the serial number label), see the [FortiCloud-managed FortiAP WiFi](#) configuration.

You can register for a free FortiCloud account at www.forticloud.com.

To create the WiFi network without a FortiCloud key, you must:

- Configure the FortiAP unit
- Add the FortiAP unit to your FortiCloud account
- Configure the FortiAP

Configuring the FortiAP unit

You need to connect and configure the FortiAP unit through the web-based manager of the FortiGate.

To configure the FortiAP unit - web-based manager

1. Connect your computer to the FortiAP Ethernet port. The FortiAP's default IP address is 192.168.1.2. The computer should have an address on the same subnet, 192.168.1.3 for example.
2. Using a browser, log in to the FortiAP as *admin*. Leave the password field empty.
3. In **WTP-Configuration**, select **FortiCloud** and enter your FortiCloud credentials. Select **Apply**.
The FortiAP is now ready to connect to FortiCloud via the Internet.

Adding the FortiAP unit to your FortiCloud account

The FortiAP must be added to the FortiCloud account that has a WiFi network already configured for it.

For an example of creating a WiFi network on FortiCloud, see [FortiCloud-managed FortiAP WiFi on page 1183](#).

To add the FortiAP to FortiCloud

1. Connect the FortiAP Ethernet cable to a network that connects to the Internet.
Restore your computer to its normal network configuration and log on to FortiCloud.
2. From the **Home** screen, go to **Inventory > AP Inventory**. Your FortiAP should be listed.
3. Then go back to the Home screen, select your AP network, and go to **Deploy APs**.
4. Select your listed FortiAP and select **Next**.
5. Make sure your platform profile is selected from the dropdown menu, and select **Next**.
6. In **Preview**, select **Deploy**.
The device will now appear listed under **Access Points**.

You will now be able to connect to the wireless network and browse the Internet. On the FortiCloud website, go to **Monitor > Report** where you can view monitoring information such as **Traffic by Period**, **Client Count by Period**, and more.

Using a FortiWiFi unit as a client

A FortiWiFi operates by default as a wireless access point. But a FortiWiFi can also operate as a wireless client, connecting the FortiGate to another wireless network.

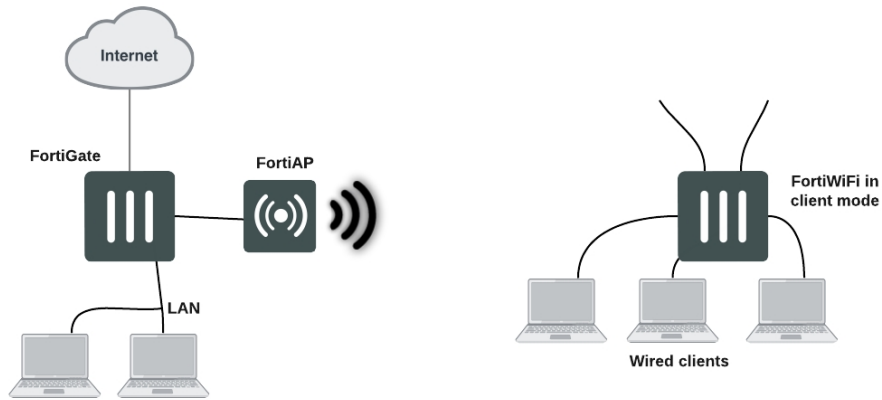

Use of client mode

In client mode, the FortiWiFi unit connects to a remote WiFi access point to access other networks or the Internet. This is most useful when the FortiWiFi unit is in a location that does not have a wired infrastructure.

For example, in a warehouse where shipping and receiving are on opposite sides of the building, running cables might not be an option due to the warehouse environment. The FortiWiFi unit can support wired users using its Ethernet ports and can connect to another access point wirelessly as a client. This connects the wired users to the network using the 802.11 WiFi standard as a backbone.

Note that in client mode the FortiWiFi unit cannot operate as an AP. WiFi clients cannot see or connect to the FortiWiFi unit in Client mode.

FortiWiFi unit in Client mode

Configuring client mode

To set up the FortiAP unit as a WiFi client, you must use the CLI. Before you do this, be sure to remove any AP WiFi configurations such as SSIDs, DHCP servers, policies, and so on.

To configure wireless client mode

1. Change the WiFi mode to client.

In the CLI, enter the following commands:

```
config system global
  set wireless-mode client
end
```

Respond "y" when asked if you want to continue. The FortiWiFi unit will reboot.

2. Configure the WiFi interface settings.

For example, to configure the client for WPA-Personal authentication on the **our_wifi** SSID with passphrase **justforus**, enter the following in the CLI:

```
config system interface
  edit wifi
    set mode dhcp
    config wifi-networks
      edit 0
        set wifi-ssid our_wifi
        set wifi-security wpa-personal
        set wifi-passphrase "justforus"
      end
    end
end
```

The WiFi interface client_wifi will receive an IP address using DHCP.

3. Configure a wifi to port1 policy.

You can use either CLI or web-based manager to do this. The important settings are:

Incoming Interface (srcintf)	wifi
Source Address (srcaddr)	all
Outgoing Interface (dstintf)	port1
Destination Address (dstaddr)	all
Schedule	always
Service	ALL
Action	ACCEPT
Enable NAT	Selected

Controlled AP selection support in FWF client mode

Use the following CLI commands to provide a more controlled AP selection method (supported in FortiWiFi client mode).

Syntax

```
config system interface
  edit {name}
    set wifi-ap-band {any | 5g-preferred | 5g-only}
  next
end
```

Support for location-based services

FortiOS supports location-based services by collecting information about WiFi devices near FortiGate-managed access points, even if the devices don't associate with the network.

Overview

WiFi devices broadcast packets as they search for available networks. The FortiGate WiFi controller can collect information about the interval, duration, and signal strength of these packets. The Euclid Analytics service uses this information to track the movements of the device owner. A typical application of this technology is to analyze shopper behavior in a shopping center. Which stores do people walk past? Which window displays do they stop to look at? Which stores do they enter and how long do they spend there? The shoppers are not personally identified, each is known only by the MAC address of their WiFi device.

After enabling location tracking on the FortiGate unit, you can confirm that the feature is working by using a specialized diagnostic command to view the raw tracking data. The Euclid Analytics service obtains the same data in its proprietary format using a JSON inquiry through the FortiGate unit's web-based manager interface.

Configuring location tracking

You can enable location tracking in any FortiAP profile, using the CLI. Location tracking is part of location-based services. Set the `station-locate` field to `enable`. For example:

```
config wireless-controller wtp-profile
  edit "FAP220B-locate"
    set ap-country US
    config platform
      set type 220B
    end
    config lbs
      set station-locate enable
    end
  end
```

Automatic deletion of outdated presence data

The FortiGate generates a log entry only the first time that station-locate detects a mobile client. No log is generated for clients that have been detected before. To log repeat client visits, previous station presence data must be deleted (flushed). The `sta-locate-timer` can flush this data periodically. The default period is 1800 seconds (30 minutes). The timer can be set to any value between 1 and 86400 seconds (24 hours). A setting of 0 disables the flush, meaning a client is logged only on the very first visit.

The timer is one of the wireless controller timers and it can be set in the CLI. For example:

```
config wireless-controller timers
  set sta-locate-timer 1800
end
```

The `sta-locate-timer` should not be set to less than the `sta-capability-timer` (default 30 seconds) because that could cause duplicate logs to be generated.

FortiPresence push REST API

When the FortiGate is located on a private IP network, the FortiPresence server cannot poll the FortiGate for information. Instead, the FortiGate must be configured to push the information to the FortiPresence server.

Enter the following command:

```
config wireless-controller wtp-profile
  edit "FP223B-GuestWiFi"
    config lbs
      set fortipresence {enable | disable}
      set fortipresence-server <ip-address> Default is 3000.
      set fortipresence-port <port>
      set fortipresence-secret <password>
      set fortipresence-project <name>
      set fortipresence-frequency <5-65535> Default is 30.
      set fortipresence-rogue {enable | disable} Enable/disable reporting of Rogue APs.
      set fortipresence-unassoc {enable | disable} Enable/disable reporting of unassociated devices.
    end
  end
end
```

Viewing device location data on the FortiGate unit

You can use the FortiGate CLI to list located devices. This is mainly useful to confirm that the location data feature is working. You can also reset device location data.

To list located devices

```
diag wireless-controller wlac -c sta-locate
```

To reset device location data

```
diag wireless-controller wlac -c sta-locate-reset
```

Example output

The following output shows data for three WiFi devices.

```
FWF60C3G11004319 # diagnose wireless-controller wlac -c sta-locate
sta_mac vfid rid base_mac freq_lst frm_cnt frm_fst frm_last intv_sum intv2_sum intv3_
sum intv_min intv_max signal_sum signal2_sum signal3_sum sig_min sig_max sig_fst
sig_last ap

00:0b:6b:22:82:61 0
FAP22B3U11005354 0 0 00:09:0f:f1:bb:e4 5745 257 708 56 651 1836 6441 0 12 -21832
1855438 -157758796 -88 -81 -84 -88 0

00:db:df:24:1a:67 0
FAP22B3U11005354 0 0 00:09:0f:f1:bb:e4 5745 42 1666 41 1625 97210 5831613 0 60 -3608
310072 -26658680 -90 -83 -85 -89 0

10:68:3f:50:22:29 0
FAP22B3U11005354 0 0 00:09:0f:f1:bb:e4 5745 102 1623 58 1565 94136 5664566 0 60 -8025
631703 -49751433 -84 -75 -78 -79 0
```

The output for each device appears on two lines. The first line contains only the device MAC address and the VLAN ID. The second line begins with the ID (serial number) of the FortiWiFi or FortiAP unit that detected the device, the AP's MAC address, and then the fields that the Euclid service uses. Because of its length, this line wraps around and displays as multiple lines.

Troubleshooting

In the following section, you will learn basic troubleshooting techniques for a secure Fortinet wireless LAN including:

- strategies for troubleshooting Fortinet wireless devices
- how to avoid common misconfigurations
- solutions to connectivity issues
- capturing and analyzing wireless traffic
- wireless debug commands

The goal of this document is to provide you with practical knowledge that you can use to troubleshoot the FortiOS wireless controller and FortiAP devices. This includes how to use tools and apply CLI commands for maintenance and troubleshooting of your wireless network infrastructure, analyze problems per OSI layer, explore diagnostics for commissioning issues regarding at-client and access point connectivity problems, and understand the packet sniffer technique as a strong troubleshooting tool.

The content is divided as follows:

FortiAP shell command through CAPWAP control tunnel

Very often, the FortiAP in the field is behind a NAT device, and access to the FortiAP through Telnet or SSH is not available. As a troubleshooting enhancement, this feature allows an AP shell command up to 127-bytes sent to the FAP, and FAP will run this command, and return the results to the controller using the CAPWAP tunnel.

The maximum output from a command is limited to 4M, and the default output size is set to 32K.

The FortiAP will only report running results to the controller after the command is finished. If a new command is sent to the AP before the previous command is finished, the previous command will be canceled.

Enter the following:

```
diag w-c wlac wtpcmd wtp_ip wtp_port cmd [cmd-to-ap] cmd: run,show,showhex,clr,r&h,r&sh
```

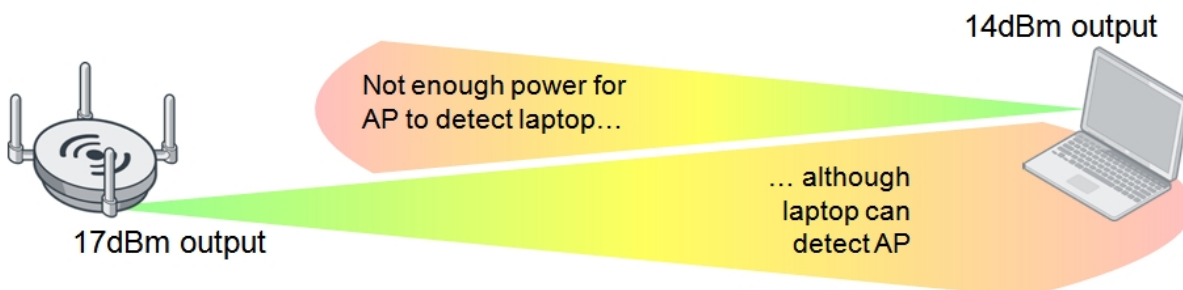

- **cmd-to-ap:** any shell commands, but AP will not report results until the command is finished on the AP
- **run:** controller sends the ap-cmd to the FAP to run
- **show:** show current results reported by the AP in text
- **showhex:** show current results reported by the AP in hex
- **clr:** clear reported results
- **r&s:** run/show
- **r&sh:** run/showhex

Signal strength issues

Poor signal strength is possibly the most common customer complaint. Below you will learn where to begin identifying and troubleshooting poor signal strength, and learn what information you can obtain from the customer to help resolve signal strength issues.

Asymmetric power issue

Asymmetric power issues are a typical problem. Wireless is two-way communication; high power access points (APs) can usually transmit a long distance, however, the client's ability to transmit is usually not equal to that of the AP and, as such, cannot return transmission if the distance is too far.

Measuring signal strength in both directions

To solve an asymmetric power issue, measure the signal strength in both directions. APs usually have enough power to transmit long distances, but sometimes battery-powered clients have a reply signal that has less power, and therefore the AP cannot detect their signal.

It is recommended that you match the transmission power of the AP to the least powerful wireless client—around 10 decibels per milliwatt (dBm) for iPhones and 14dBm for most laptops.

Even if the signal is strong enough, other devices may be emitting radiation as well, causing interference. To identify the difference, read the client Rx strength from the FortiGate GUI (under **Monitor > WiFi Client Monitor**) or CLI.

The **Signal Strength/Noise** value provides the received signal strength indicator (RSSI) of the wireless client. For example, A value of -85dBm to -95dBm is equal to about 10dB levels; this is not a desirable signal strength. In the following screenshot, one of the clients is at 18dB, which is getting close to the perimeter of its range.

SSID	FortiAP	IP	Device	Channel	Bandwidth Tx/Rx	Signal Strength/Noise	Signal
MavisF	FAP28C3X13000119 (1)	10.0.2.8	e8:91:20:90:6e:23	6	1 kbps	29 dB	
MavisF	FP320C3X14000668 (1)	192.168.255.112	1c:69:a5:c8:e8:3e	11	80 bps	35 dB	
MavisF	FP320C3X14000668 (2)	192.168.255.101	58:55:ca:36:28:7d	44	12 kbps	51 dB	
MavisF	FAP28C3X13000119 (1)	10.0.2.9	Acer A1-830 Tablet	6	543 bps	18 dB	
MavisF	FAP28C3X13000119 (1)	10.0.2.13	08:ed:b9:4f:98:ad	6	16 kbps	31 dB	
MavisF	FP320C3X14000668 (1)	192.168.255.115	Ellas_Tablet	11	0 bps	35 dB	

The Signal Strength/Noise value received from the FortiAP by clients, and vice versa, should be within the range of -20dBm to -65dBm.

You can also confirm the transmission (Tx) power of the controller on the AP profile (wtp-profile) and the FortiAP (iwconfig), and check the power management (auto-Tx) options.

Controller configured transmitting power - CLI:

```
config wireless-controller wtp-profile
config <radio>
```

```
show
(the following output is limited to power levels)
auto-power-level : enable
auto-power-high : 17
auto-power-low : 10
```

Actual FortiAP transmitting power - CLI:

```
iwconfig wlan00
```

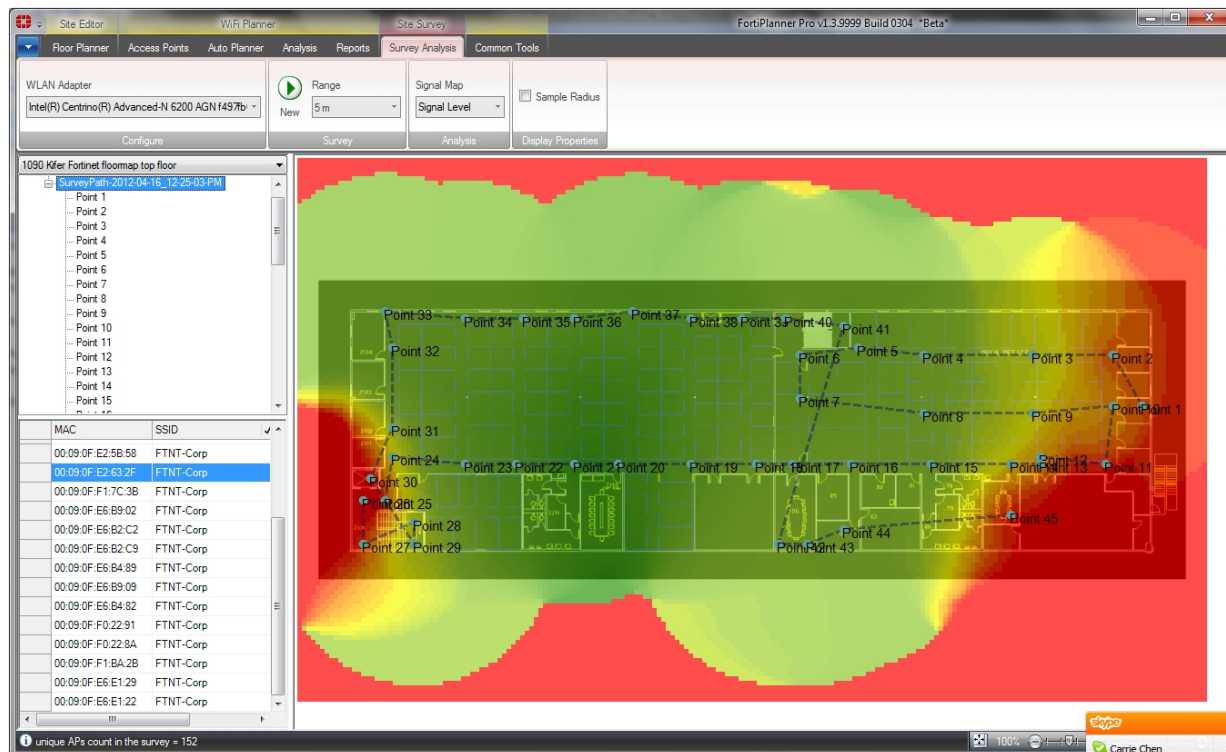

Result:

```
wlan00 IEEE 802.11ng ESSID:"signal-check"
Mode:Master Frequency:2.412 GHz Access Point:<MAC add>
Bit Rate:130 Mb/s Tx-Power=28 dBm
```

Using FortiPlanner PRO with a site survey

The most thorough method to solve signal strength issues is to perform a site survey. To this end, Fortinet offers the FortiPlanner, downloadable at http://www.fortinet.com/resource_center/product_downloads.html.

Sample depiction of a site survey using FortiPlanner

The site survey provides you with optimal placement for your APs based on the variables in your environment. You must provide the site survey detailed information including a floor plan (to scale), structural materials, and more. It will allow you to place the APs on the map and adjust the radio bands and power levels while providing you with visual wireless coverage.

Below is a list of mechanisms for gathering further information on the client for Rx strength. The goal is to see how well the client is receiving the signal from the AP. You can also verify FortiAP signal strength on the client

using WiFi client utilities, or third party utilities such as InSSIDer or MetaGeek Chanalyzer. You can get similar tools from the app stores on Android and iOS devices.

- Professional Site Survey software (Ekahau, Airmagnet survey Pro, FortiPlanner)
- InSSIDer
- On Windows: “*netsh wlan show networks mode=bssid*” (look for the BSSID, it's in % not in dBm!)
- On MacOS: Use the “*airport*” command:

```
"/System/Library/PrivateFrameworks/Apple80211.framework/Versions/A/Resources/airport" airport -s | grep <the_bssid>
```

 (live scan each time)
- On Droid: WiFiFoFum

Frequency interference

If the wireless signal seems to be strong but then periodically drops, this may be a symptom of frequency interference. Frequency interference is when another device also emits radio frequency using the same channel, co-channel, or adjacent channel, thereby overpowering or corrupting your signal. This is a common problem on a 2.4GHz network.

There are two types of interference: coherent and non-coherent.

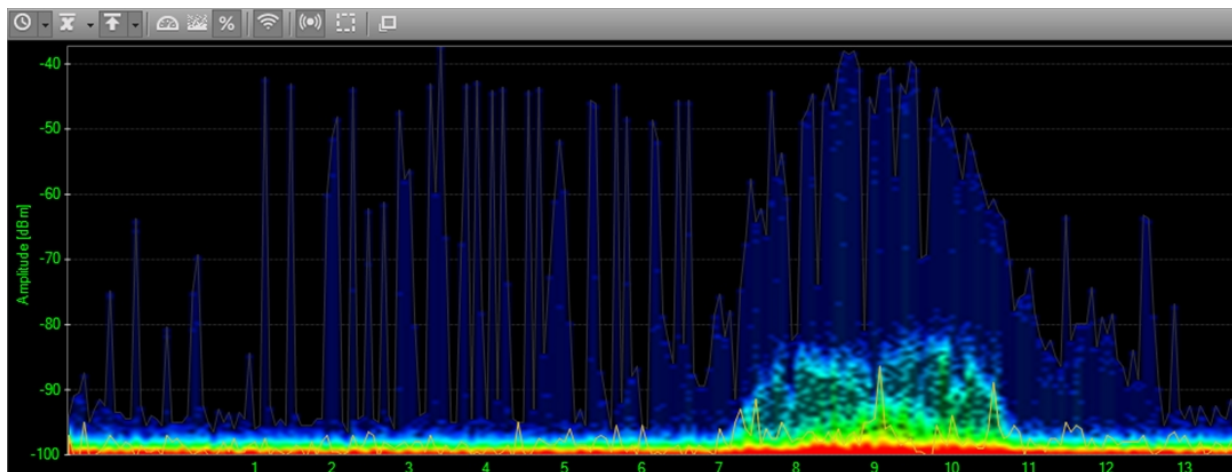

- **Coherent interference:** a result of another device using the same channel as your AP, or poor planning of a wireless infrastructure (perhaps the other nearby APs are using the same channel or the signal strength is too high).
- **Non-coherent interference:** a result of other radio signals such as bluetooth, microwave, cordless phone, or (as in medical environments) x-ray machines.

Most common and simple solution for frequency interference is to change your operation channel. Typically, the channel can be set from 1 to 11 for the broadcast frequency, although you should always use channels 1, 6, and 11 on the 2.4GHz band.

Another solution, if it's appropriate for your location, is to use the 5GHz band instead.

MetaGeek Chanalyzer

You can perform a site survey using spectrum analysis at various points in your environment looking for signal versus interference/noise. MetaGeek Chanalyzer is an example of a third party utility which shows a noise threshold.

Note that a signal of -95dBm or less will be ignored by Fortinet wireless adapters.

Throughput issues

Sometimes communication issues can be caused by low performance.

Testing the link

You can identify delays or lost packets by sending ping packets from your wireless client. If there is more than 10ms of delay, there may be a problem with your wireless deployment, such as:

- a weak transmit signal from the client (the host does not reach the AP)
- the AP utilization is too high (your AP could be saturated with connected clients)
- interference (third party signal could degrade your AP or client's ability to detect signals between them)
- weak transmit power from the AP (the AP does not reach the host) -- not common in a properly deployed network, unless the client is too far away

Keep in mind that water will also cause a reduction in radio signal strength for those making use out of outdoor APs or wireless on a boat.

Performance testing

If the FortiAP gives bad throughput to the client, the link may drop. The throughput or performance can be measured on your smartphone with third party applications tool such as iPerf and jPerf.

Measuring file transfer speed

Another way to get a sense of your throughput issues is to measure the speed of a file transfer on your network. Create a test file at a specific size and measure the speed at which Windows measures the transfer. The command below will create a 50MB file.

- `fsutil file createnew test.txt 52428800`

The following image shows a network transfer speed of just over 24Mbps. The theoretical speed of 802.11g is 54Mbps, which is what this client is using. A wireless client is never likely to see the theoretical speed.

TKIP limitation

If you find that throughput is a problem, avoid WPA security encrypted with Temporal Key Integrity Protocol (TKIP) as it supports communications only at 54Mbps. Use WPA-2 AES instead.

Speeds are very much based on what the client computer can handle as well. The maximum client connection rate of 130Mbps is for 2.4GHz on a 2x2, or 300Mbps for 5Ghz on a 2x2 (using shortguard and channel bonding enabled).

If you want to get more than 54Mbps with 802.11n, do not use legacy TKIP, use CCMP instead. This is standard for legacy compatibility.

Preventing IP fragmentation in CAPWAP

TKIP is not the only possible source of decreased throughput. When a wireless client sends jumbo frames using a CAPWAP tunnel, it can result in data loss, jitter, and decreased throughput.

Using the following commands you can customize the uplink rates and downlink rates in the CAPWAP tunnel to prevent fragmentation and avoid data loss.

```
config wireless-controller wtp
  edit new-wtp
    set override-ip-fragment enable
    set ip-fragment-preventing [tcp-mss-adjust | icmp-unreachable]
    set tun-mtu-uplink [0 | 576 | 1500]
    set tun-mtu-downlink [0 | 576 | 1500]
  end
end
```

The default value is 0, however the recommended value will depend on the type of traffic. For example, IPsec in tunnel mode has 52 bytes of overhead, so you might use 1400 or less for uplink and downlink.

Slowness in the DTLS response

It's important to know all the elements involved in the CAPWAP association:

- Request
- Response
- DTLS
- Join
- Configuration

All of these are bidirectional. So if the DTLS response is slow, this might be the result of a configuration error. This issue can also be caused by a certificate during discovery response. You can read more about this in [RFC 5416](#).

Connection issues

If the client has a connectivity issue that is not due to signal strength, the solution varies by the symptom.

Client connection issues

1. If client is unable to connect to FortiAP:

- Make sure the client's security and authentication settings match with FortiAP and check the certificates as well.
 - Try upgrading the Wi-Fi adapter driver and FortiGate/FortiAP firmware.
 - If other clients can connect, it could be interoperability; run debug commands and sniffer packets.
 - Look for rogue suppression by sniffing the wireless traffic and looking for the disconnect in the output (using the AP or wireless packet sniffer).
 - Try changing the IEEE protocol from 802.11n to 802.11bg or 802.11a only.
2. If the client drops and reconnects:
 - The client might be de-authenticating periodically. Check the sleep mode on the client.
 - The issue could be related to power-saver settings. The client may need to update drivers.
 - The issue could also be caused by flapping between APs. Check the roaming sensitivity settings on the client or the preferred wireless network settings on the client—if another WiFi network is available, the client may connect to it if it is a preferred network. Also, check the DHCP configuration as it may be an IP conflict.
 3. If the client drops and never connects:
 - It could have roamed to another SSID, so check the standby and sleep modes.
 - You may need to bring the interface up and down.
 4. If the client connects, but no IP address is acquired by the client:
 - Check the DHCP configuration and the network.
 - It could be a broadcast issue, so check the WEP encryption key and set a static IP address and VLANs.

Debug

You should also enable client debug on the controller for problematic clients to see the stage at which the client fails to connect. Try to connect from the problematic client and run the following debug command, which allows you to see the four-way handshake of the client association:

```
diagnose wireless-controller wlac sta_filter <client MAC address> 2
```

Example of a successful client connection:

The following is a sample debug output for the above command, with successful association/DHCP phases and PSK key exchange (identified in color):

```

```

where:

- **orange** represents the association phase,
- **blue** represents the PSK exchange,
- and **green** represents the DHCP phase.

It is important to note the messages for a correct association phase, four-way handshake, and DHCP phase.

Checking WiFi password

Admins can view plain text passwords (captive-portal-radius-secret and passphrase) under config wireless-controller vap.

Note that security must be set as a WPA-personal setting.

FortiAP connection issues

Clients are not the only device that can fail to connect, of course. A communication problem could arise from the FortiAP.

Some examples include:

- The FortiAP is not connecting to the wireless controller.
- One FortiAP intermittently disconnects and re-connects.
- All FortiAPs intermittently disconnect and re-connect.
- Unable to Telnet to FortiAP from controller/administrator workstation.

In the above cases:

- Check networking on the distribution system for all related FortiAPs.
- Check the authorization status of managed APs from the wireless controller.

- Restart the `cw_acd` process (**Note:** All APs will drop if you do this, and you may be troubleshooting just one AP).
- Check the controller crash log for any wireless controller daemon crash using the following command:

```
diagnose debug crashlog read
```

Debug

For a quick assessment of the association communication between the controller and the FortiAP, run the following sniffer command to see if you can verify that the AP is communicating to the controller by identifying the CAPWAP communication:

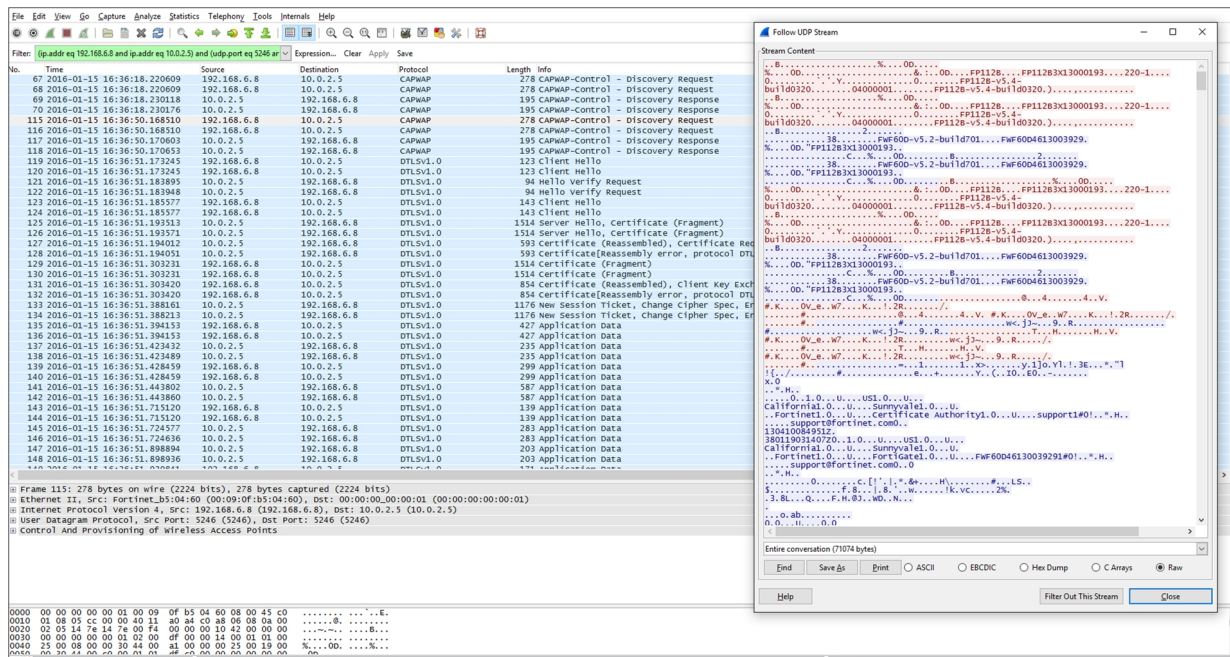

```
diagnose sniff packet <interface_name> "port 5246" 4
```

If you do not see this communication, then you can investigate the network or the settings on the AP to see why it is not reaching the controller.

The following command allows you to collect verbose output from the sniff that can be converted to a PCAP and viewed in Wireshark.

```
diagnose sniff packet <interface_name> "port 5246" 6 o 1
```

The image below shows the beginning of the AP's association to the controller. You can see the discovery Request and Response at the top.

Throughout debugging it is recommended to:

- Enable Telnet login to the FortiAP device so that you can log in and issue local debugging commands:

```
config wireless-controller wtp
edit "<FortiAP_serial_number>"
set override-allowaccess {disable|enable}
set allowaccess {telnet | http | https | ssh}
end
```

- Try to connect to the wireless controller from the problematic FortiAP to verify routes exist.

- Enable wtp (FortiAP) debugging on the wireless controller for problematic FortiAPs to determine the point at which the FortiAP fails to connect:

```
diag wireless-controller wlap wtp_filter FP112B3X13000193 0-192.168.6.8:5246 2
(replace the serial number and IP address of the FortiAP)
di de console timestamp en
di de application cw_acd 0x7ff
di de en
```

Example of a successful AP and controller association:

The previous debug command provides similar output to the sample debug message below for a successful association between the FortiAP and the wireless controller. This includes the elements of the CAPWAP protocol; the Request, Response, DTLS, Join, and Configuration (identified in color). All of these are bi-directional, so if the DTLS response is slow, it may be an example of a configuration error.

where:

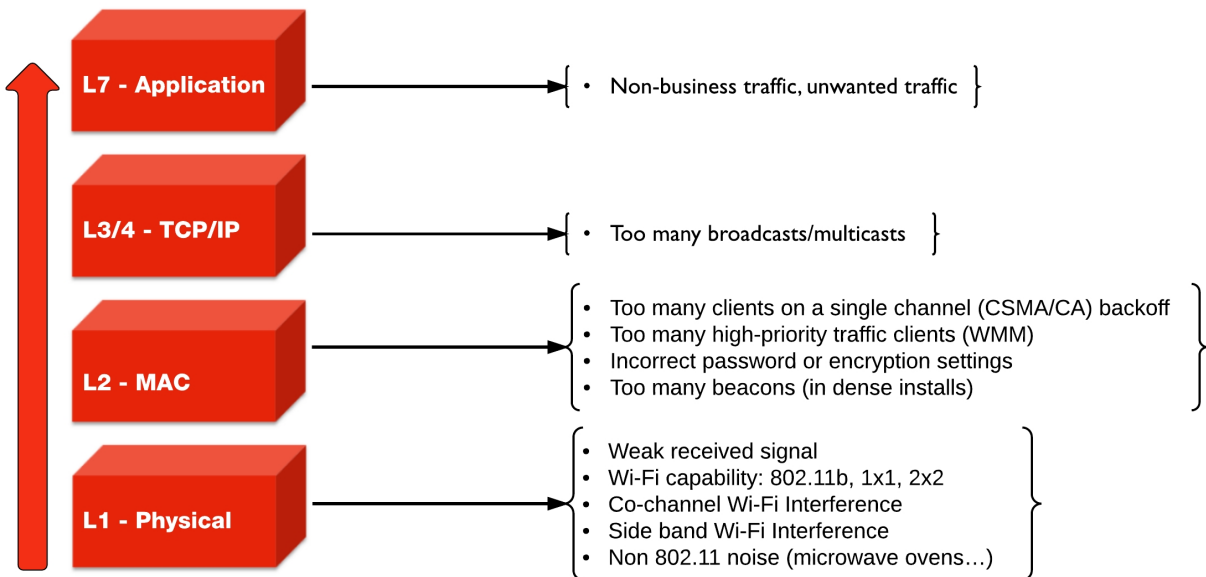

- **orange** represents the Discovery phase,
- **blue** indicates that the control channels have been established using DTLS,
- **green** represents the access point Discovery and Join phase,
- **purple** represents the Clear Text channel,
- and **pink** indicates that the FortiAP successfully connected to the wireless controller.

General problems

Not all WiFi problems are related to signal strength, interference, or misconfiguration. The following OSI model identifies some of the more common issues per layer.

Best practices for troubleshooting vary depending on the affected layer (see below).

Common sources of wireless issues

Best practices for Layer 1

Common physical layer issues include:

- Weak received signal,
- WiFi capability: 802.11b, 1x1, 2x2,
- Co-channel WiFi interference,
- Side band WiFi interference,
- Non 802.11 noise (microwave ovens...).

To avoid physical layer issues:

- Determine RST (Receiver Sensitivity Threshold) for your device, or use -70dBm as a rule of thumb.
- Match AP TX output power to the client TX output power.
 - **Note:** iPhone TX power is only 10dBm.
- Use DFS (Dynamic Frequency Selection) for high performance data 20/40 MHz.
- Use 5GHz UNII-1 & 3 (Non-DFS) bands with static channel assignment for latency-sensitive applications.
- Do not use 40MHz channels in 2.4 GHz band (channel bonding is not allowed in FortiOS).

Best practices for Layer 2

Common data link (MAC) layer issues include:

- Too many clients on a single channel (CSMA/CA) backoff,
- Too many high-priority traffic clients (WMM),
- Incorrect password or encryption settings,
- Too many beacons (in dense installs).

To avoid data link layer issues:

- Only use CCMP/AES (WPA2) encryption (not TKIP).
- In high density deployments, turn off SSID broadcast or turn down SSID rates. Review and possibly reduce the beacon interval.
- Determine the best cell size for applications:
 - For few users and low bandwidth latency sensitive applications, use high transmit power to create larger cells.
 - For high performance/high capacity installations, use lower transmit power to create smaller cells (set FortiPlanner at 10dBm TX power), but bear in mind that this will require more roaming.

Cells and co-channel interference

In high density deployments, multiple APs are used, and each one services an area called a cell. However, these cells can cause interference with each other. This is a common problem. The radio signal from one AP interferes with, or cancels out, the radio signal from another AP.

In the following diagram, note the interference zone created by one radio, causing interference on its neighbouring APs.

The interference zone can be twice the radius of the signal, and the signal at its edge can be -67dBm.

Reducing co-channel interference

For best results, use a 'honeycomb' pattern as a deployment strategy. The idea is to *stagger* repeated channels furthest from each other to avoid interference.

Best practices for Layer 3 and above

For TCP/IP layers and above, a common source of latency, or slowness in the wireless traffic, is too many broadcasts or multicasts. These types of issues can result from non-business and/or unwanted traffic.

To resolve issues at the TCP/IP layer and above:

- Identify business-critical applications.
- Use Application Control, Web Filtering, Traffic Shaping, and QoS to prioritize applications.
 - Identify unwanted traffic, high-bandwidth web-related traffic, and use Security Profiles.
 - Use the traffic shaper on a policy to rate-limit this traffic.

These configurations are performed directly on the FortiGate.

Packet sniffer

Capturing the traffic between the controller and the FortiAP can help you identify most FortiAP and client connection issues.

This section describes the following recommended packet sniffing techniques:

- [CAPWAP packet sniffer](#)
- [Wireless traffic packet sniffer](#)

CAPWAP packet sniffer

The first recommended technique consists of sniffing the CAPWAP traffic.

- Enable plain control on the controller and on the FortiAP to capture clear control traffic on UDP port 5246.
 - On the controller:

```
diagnose wireless-controller wlac plain-ctl <FortiAP_serial_number> 1
```

Result:

```
WTP 0-FortiAP2223X11000107 Plain Control: enabled
```

- On the FortiAP:

```
cw_diag plain-ctl 1
```

Result:

```
Current Plain Control: enabled
```

Note that some issues are related to the keep-alive for control and data channel.

- Data traffic on UDP port 5247 is not encrypted. The data itself is encrypted by the wireless security mechanism.

Data traffic is helpful to troubleshoot most of the issues related to station association, EAP authentication, WPA key exchange, roaming, and FortiAP configuration.

You can also set up a host or server to which you can forward the CAPWAP traffic:

1. Configure the host/server to which CAPWAP traffic is forwarded:

```
diagnose wireless-controller wlac sniff-cfg <Host_IP_address> 88888
```

Result:

```
Current Sniff Server: 192.168.25.41, 23352
```

2. Choose which traffic to capture, the interface to which the FortiAP is connected, and the FortiAP's serial number:

```
diagnose wireless-controller wlac sniff <interface_name> <FortiAP_serial_number> 2
```

Result:

```
WTP 0-FortiAP2223X11000107 Sniff: intf port2 enabled (control and data message)
```

In the above syntax, the '2' captures the control and data message—'1' would capture only the control message, and '0' would disable it.

3. Run Wireshark on the host/server to capture CAPWAP traffic from the controller.
 - Decode the traffic as IP to check inner CAPWAP traffic.

Example CAPWAP packet capture

The following image shows an example of a CAPWAP packet capture, where you can see: the Layer 2 header; the sniffed traffic encapsulated into Internet Protocol for transport; CAPWAP encapsulated into UDP for sniffer purpose and encapsulated into IP; CAPWAP control traffic on UDP port 5246; and CAPWAP payload.

No.	Time	Source	Destination	Protocol	Info
1	0.000000	192.168.35.82	192.168.35.80	CAPWAP	Control Msg - Echo Request

Wireless traffic packet sniffer

The second recommended technique consists of sniffing the wireless traffic directly 'on the air' using your FortiAP.

Wireless traffic packet capture

Packet captures are useful for troubleshooting all wireless client related issues because you can verify data rate and 802.11 parameters, such as radio capabilities, and determine issues with wireless signal strength, interference, or congestion on the network.

A radio can only capture one frequency at a time; one of the radios is set to sniffer mode depending on the traffic or channel required. You must use two FortiAPs to capture both frequencies at the same time.

- Set a radio on the FortiAP to monitor mode.

```
iwconfig wlan10
```

Result:

```
wlan10 IEEE 802.11na ESSID:""  
Mode:Monitor Frequency:5.18 GHz Access Point: Not-Associated
```

- The capture file is stored under the temp directory as *wl_sniff.pcap*

```
/tmp/wl_sniff.pcap
```

- Remember that the capture file is only stored temporarily. If you want to save it, upload it to a TFTP server before rebooting or changing the radio settings.
- The command `cp wl_sniff.pcap newname.pcap` allows you to rename the file.

- Rather than TFTP the file, you can also log in to the AP and retrieve the file via the web interface. Move the file using the command: `mv name /usr/www`

You can verify the file was moved using the command `cd/usr/www` and then browsing to: `<fortiAP_IP>/filename`

Syntax

The following syntax demonstrates how to set the radio to sniffer mode (configurable from the CLI only). Sniffer mode provides options to filter for specific traffic to capture. Notice that you can determine the buffer size, which channel to sniff, the AP's MAC address, and select if you want to sniff the beacons, probes, controls, and data channels.

```
configure wireless-controller wtp-profile
  edit <profile_name>
    configure <radio>
      set mode sniffer
      set ap-sniffer-bufsize 32
      set ap-sniffer-chan 1
      set ap-sniffer-addr 00:00:00:00:00:00
      set ap-sniffer-mgmt-beacon enable
      set ap-sniffer-mgmt-probe enable
      set ap-sniffer-mgmt-other enable
      set ap-sniffer-ctl enable
      set ap-sniffer-data enable
    end
  end
```

Once you've performed the previous CLI configuration, you'll be able to see the packet sniffer mode selected in the GUI dashboard under **WiFi & Switch Controller > FortiAP Profiles** and **WiFi & Switch Controller > Managed FortiAPs**. Bear in mind that if you change the mode from the GUI, you'll have to return to the CLI to re-enable the Sniffer mode.

To disable the sniffer profile in the CLI, use the following commands:

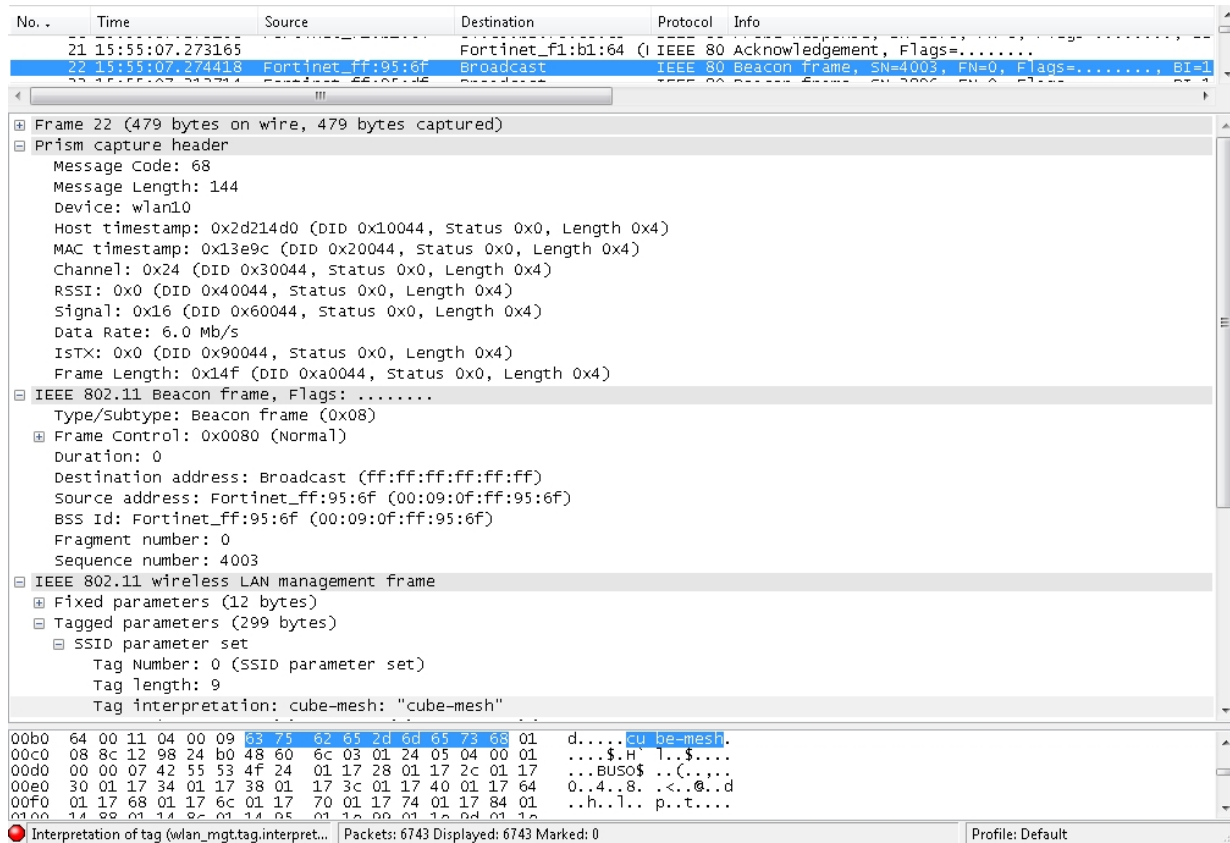

```
config wireless-controller wtp-profile
  edit <profile_name>
    config <radio>
      set ap-sniffer-mgmt-beacon disable
      set ap-sniffer-mgmt-probe disable
      set ap-sniffer-mgmt-other disable
      set ap-sniffer-ctl disable
      set ap-sniffer-data disable
    end
  end
```

If you change the radio mode before sending the file *wl_sniff.cap* to an external TFTP, the file will be deleted and you will lose your packet capture.

Example AP packet capture

The following image shows an example of the AP packet capture. Note the capture header showing channel 36; the beacon frame; the source, destination, and BSSID of the beacon frame; and the SSID of the beacon frame.

Useful debugging commands

For a comprehensive list of useful debug options you can use the following help commands on the controller:

```
diagnose wireless-controller wlac help
(this command lists the options available that pertain to the wireless controller)
```

```
diagnose wireless-controller wlwtp help
(this command lists the options available that pertain to the AP)
```

Sample outputs

Syntax

```
diagnose wireless-controller wlac -c vap
(this command lists the information about the virtual access point, including its MAC address, the BSSID, its SSID, the interface name, and the IP address of the APs that are broadcasting it)
```

Result:

```
bssid          ssid   intf    vfid:ip-port  rId  wId
00:09:0f:d6:cb:12 Office Office  ws (0-192.168.3.33:5246) 0 0
00:09:0f:e6:6b:12 Office Office  ws (0-192.168.1.61:5246) 0 0
06:0e:8e:27:dc:48 Office Office  ws (0-192.168.3.36:5246) 0 0
0a:09:0f:d6:cb:12 public publicAP ws (0-192.168.3.33:5246) 0 1
```

Syntax

```
diagnose wireless-controller wlac -c darrp
```

(this command lists the information pertaining to the radio resource provisioning statistics, including the AP serial number, the number of channels set to choose from, and the operation channel. Note that the 5GHz band is not available on these APs listed)

Result:

wtp_id	rId	base_mac	index	nr_chan	vfid	5G	oper_chan	age
FAP22A3U10600400	0	00:09:0f:d6:cb:12	0	3	0	No	1	87588
FW80CM3910601176	0	06:0e:8e:27:dc:48	1	3	0	No	6	822

Support for extension information for wtp, vap, and station

You can enable or disable extension information at `wtp-profile`, and use the diagnose option below to print out the detail of extension information.

Syntax

```
config wireless-controller wtp-profile
edit test
set lldp [enable | disable]
set ext-info [enable | disable] --> Enable/disable station/VAP/radio extension information.
end
end

diagnose wireless-controller wlac -d [wtp | vap | sta]
```

where:

- `wlac -d wtp [SN|name] [reset]` --> list or reset wtp info(data)
- `wlac -d vap [bssid] [reset]` --> list or reset vap info(data)
- `wlac -d sta [mac] [reset]` --> list or reset sta info(data)

Reference

This chapter provides some reference information pertaining to wireless networks.

FortiAP web-based manager

You can access the FortiAP unit's built-in web-based manager. This is useful to adjust settings that are not available through the FortiGate unit's WiFi Controller. Logging into the FortiAP web-based manager is similar to logging into the FortiGate web-based manager.

System information

Status

The **Status** section provides information about the FortiAP unit.

Host Name	FAP22B3U11005354 [Change]
Serial Number	FAP22B3U11005354
Region Code	A
Firmware Version	FortiAP-220B v5.0,build064,140117 (GA) [Update]
Network Status	0.0.0.0/0.0.0.0/0.0.0.0 (Mon Jun 2 12:50:05 2014)
System Time	Tue May 27 13:00:39 2014
Current Administrator	admin [Change Password]
System Configuration	Last Backup: N/A [Backup] [Restore]
Uptime	7 day(s) 2 hour(s) 4 min(s)
CPU Usage	<div><div></div></div> 1%
Memory Usage	<div><div></div></div> 35%
AC Discovery Status	Discovering AC ...

You can:

- Select **Change** to change the **Host Name**.
- Select **Update** in **Firmware Version** to upload a new FortiAP firmware file from your computer.
- Select **Change Password** to change the administrator password.
- Select **Backup** to save the current FortiAP configuration as a file on your computer.
- Select **Restore** to load a configuration into your FortiAP unit from a file on your computer.

Network configuration

Select DHCP or select Static and specify the IP address, netmask, and gateway IP address. **Administrative Access** settings affect access after the FortiAP has been authorized. By default, **HTTP** access needed to access the FortiAP web-based manager is enabled, but **Telnet** access is not enabled.

Connectivity

These settings determine how the FortiAP unit connects to the FortiGate WiFi controller.

Uplink	Ethernet - wired connection to the FortiGate unit (default) Mesh - WiFi mesh connection Ethernet with mesh backup support
Mesh AP SSID	Enter the SSID of the mesh root. Default: fortinet.mesh.root
Mesh AP Password	Enter password for the mesh SSID.
Ethernet Bridge	Bridge the mesh SSID to the FortiAP Ethernet port. This is available only when Uplink is Mesh .

WTP configuration

AC Discovery Type settings affect how the FortiAP unit discovers a FortiGate WiFi controller. By default, this is set to Auto which causes the FortiAP unit to cycle through all of the discovery methods until successful. For more information see Controller discovery methods.

AC Discovery Type	Static, DHCP, DNS, Broadcast, Multicast, Auto
AC Control Port	Default port is 5246.
AC IP Address 1 AC IP Address 2 AC IP Address 3	You enter up to three WiFi controller IP addresses for static discovery. Routing must be properly configured in both directions.
AC Host Name 1 AC Host Name 2 AC Host Name 3	As an alternative to AC IP addresses, you can enter their fully qualified domain names (FQDNs).
AC Discovery Multicast Address	224.0.1.140
AC Discovery DHCP Option Code	When using DHCP discovery, you can configure the DHCP server to provide the controller address. By default the FortiAP unit expects this in option 138.

AC Data Channel Security by default accepts either DTLS-encrypted or clear text data communication with the WiFi controller. You can change this setting to require encryption or to use clear text only.

Wireless information

The Wireless Information page provides current information about the operation of the radios and the type Uplink in use.

Wireless radio channels

IEEE 802.11a/n channels

The following table lists the channels supported on FortiWiFi products that support the IEEE 802.11a and 802.11n wireless standards. 802.11a is available on FortiWiFi models 60B and higher. 802.11n is available on FortiWiFi models 80CM and higher.

All channels are restricted to indoor usage except in the Americas, where both indoor and outdoor use is permitted on channels 52 through 64 in the United States.

IEEE 802.11a/n (5-GHz Band) channel numbers

Channel number	Frequency (MHz)	Regulatory Areas				
		Americas	Europe	Taiwan	Singapore	Japan
34	5170					•
36	5180	•	•		•	
38	5190					
40	5200	•	•		•	•
42	5210					
44	5220	•	•		•	•
46	5230					
48	5240	•	•		•	•
149	5745	•		•	•	
153	5765	•		•	•	
157	5785	•		•	•	
161	5805	•		•	•	
165	5825	•			•	

IEEE 802.11b/g/n channel numbers

The following table lists IEEE 802.11b/g/n channels. All FortiWiFi units support 802.11b and 802.11g. Newer models also support 802.11n.

Mexico is included in the Americas regulatory domain. Channels 1 through 8 are for indoor use only. Channels 9 through 11 can be used indoors and outdoors. You must make sure that the channel number complies with the regulatory standards of Mexico.

IEEE 802.11b/g/n (2.4-GHz Band) channel numbers

Channel number	Frequency (MHz)	Regulatory Areas			
		Americas	EMEA	Israel	Japan
1	2412	•	•	indoor	•
2	2417	•	•	indoor	•
3	2422	•	•	indoor	•

View all country and regcodes/regulatory domains

The following CLI command can be entered to view a list of the country and regcodes/regulatory Domains supported by Fortinet:

```
cw_diag -c all-countries
```

Below is a table showing a sample of the list displayed by entering this command:

Country-code	Region-code	Domain	ISO-name	Name
0	A	FCC3 & FCCA	NA	NO_COUNTRY_SET

Country-code	Region-code	Domain	ISO-name	Name
8	W	NULL1 & WORLD	AL	ALBANIA
12	W	NULL1 & WORLD	DZ	ALGERIA
16	A	FCC3 & FCCA	AS	AMERICAN SAMOA
...

WiFi event types

Event type	Description
rogue-ap-detected	A rogue AP has been detected (generic).
rogue-ap-off-air	A rogue AP is no longer detected on the RF side.
rogue-ap-on-wire	A rogue AP has been detected on wire side (connected to AP or controller L2 network).
rogue-ap-off-wire	A rogue AP is no longer detected on wire.
rogue-ap-on-air	A rogue AP has been detected on the RF side.
fake-ap-detected	A rogue AP broadcasting on the same SSIDs that you have in your managed APs has been detected.
fake-ap-on-air	The above fake AP was detected on the RF side.

FortiAP CLI

The FortiAP CLI controls radio and network operation through the use of variables manipulated with the `cfg` command. There are also diagnostic commands.

The `cfg` command include the following

<code>cfg -s</code>	List variables.
<code>cfg -a var=value</code>	Add or change a variable value.
<code>cfg -c</code>	Commit the change to flash.
<code>cfg -x</code>	Reset settings to factory defaults.
<code>cfg -r var</code>	Remove variable.

<code>cfg -e</code>	Export variables.
<code>cfg -h</code>	Display help for all commands.

The configuration variables are:

Var	Description and Values
AC_CTL_PORT	WiFi Controller control (CAPWAP) port. Default 5246.
AC_DATA_CHAN_SEC	Data channel security. 0 - Clear text 1 - DTLS (encrypted) 2 - Accept either DTLS or clear text (default)
AC_DISCOVERY_TYPE	1 - Static. Specify WiFi Controllers 2 - DHCP 3 - DNS 5 - Broadcast 6 - Multicast 0 - Cycle through all of the discovery types until successful.
AP_IPADDR AP_NETMASK IPGW	These variables set the FortiAP unit IP address, netmask and default gateway when ADDR_MODE is STATIC. Default 192.168.1.2 255.255.255.0, gateway 192.168.1.1.
AC_HOSTNAME_1 AC_HOSTNAME_2 AC_HOSTNAME_3	WiFi Controller host names for static discovery.
AC_IPADDR_1 AC_IPADDR_2 AC_IPADDR_3	WiFi Controller IP addresses for static discovery.
AC_DISCOVERY_DHCP_OPTION_CODE	Option code for DHCP server. Default 138.
AC_DISCOVERY_MC_ADDR	Multicast address for controller discovery. Default 224.0.1.140.

Var	Description and Values
ADDR_MODE	How the FortiAP unit obtains its IP address and netmask. DHCP - FortiGate interface assigns address. STATIC - Specify in AP_IPADDR and AP_NETMASK. Default is DHCP.
ADMIN_TIMEOUT	Administrative timeout in minutes. Applies to Telnet and web-based manager sessions. Default is 5 minutes.
AP_MGMT_VLAN_ID	Non-zero value applies VLAN ID for unit management. Default: 0.
AP_MODE	FortiAP operating mode. 0 - Thin AP (default) 2 - Unmanaged Site Survey mode. See SURVEY variables.
BAUD_RATE	Console data rate: 9600, 19200, 38400, 57600, or 115200 baud.
DNS_SERVER	DNS Server for clients. If ADDR_MODE is DHCP the DNS server is automatically assigned.
FIRMWARE_UPGRADE	Default is 0.
HTTP_ALLOW	Access to FortiAP web-based manager 1 - Yes (default), 0 - No.
LED_STATE	Enable/disable status LEDs. 0 - LEDs enabled, 1 - LEDs disabled, 2 - follow AC setting.
LOGIN_PASSWD	Administrator login password. By default this is empty.
STP_MODE	Spanning Tree Protocol. 0 is off. 1 is on.
TELNET_ALLOW	By default (value 0), Telnet access is closed when the FortiAP unit is authorized. Set value to 1 to keep Telnet always available.
WTP_LOCATION	Optional string describing AP location.
Mesh variables	

Var	Description and Values
MESH_AP_BGSCAN	<p>Enable or disable background mesh root AP scan.</p> <p>0 - Disabled</p> <p>1 - Enabled</p>
MESH_AP_BGSCAN_RSSI	<p>If the root AP's signal is weak, and lower than the received signal strength indicator (RSSI) threshold, the WiFi driver will immediately start a new round scan and ignore the configured MESH_AP_BGSCAN_PERIOD delays. Set the value between 0-127.</p> <p>After the new round scan is finished, a scan done event is passed to wtp daemon to trigger roaming.</p>
MESH_AP_BGSCAN_PERIOD	Time in seconds that a delay period occurs between scans. Set the value between 1-3600.
MESH_AP_BGSCAN_IDLE	Time in milliseconds. Set the value between 0-1000.
MESH_AP_BGSCAN_INTV	Time in milliseconds between channel scans. Set the value between 200-16000.
MESH_AP_BGSCAN_DUR	Time in milliseconds that the radio will continue scanning the channel. Set the value between 10-200.
MESH_AP_SCANCHANLIST	Specify those channels to be scanned.
MESH_AP_TYPE	<p>Type of communication for backhaul to controller:</p> <p>0 - Ethernet (default)</p> <p>1 - WiFi mesh</p> <p>2 - Ethernet with mesh backup support</p>
MESH_AP_SSID	SSID for mesh backhaul. Default: fortinet.mesh.root
MESH_AP_BSSID	WiFi MAC address
MESH_AP_PASSWD	Pre-shared key for mesh backhaul.
MESH_ETH_BRIDGE	<p>1 - Bridge mesh WiFi SSID to FortiAP Ethernet port. This can be used for point-to-point bridge configuration. This is available only when MESH_AP_TYPE =1.</p> <p>0 - No WiFi-Ethernet bridge (default).</p>

Var	Description and Values
MESH_MAX_HOPS	Maximum number of times packets can be passed from node to node on the mesh. Default is 4.
The following factors are summed and the FortiAP associates with the lowest scoring mesh AP.	
MESH_SCORE_HOP_WEIGHT	Multiplier for number of mesh hops from root. Default 50.
MESH_SCORE_CHAN_WEIGHT	AP total RSSI multiplier. Default 1.
MESH_SCORE_RATE_WEIGHT	Beacon data rate multiplier. Default 1.
MESH_SCORE_BAND_WEIGHT	Band weight (0 for 2.4GHz, 1 for 5GHz) multiplier. Default 100.
MESH_SCORE_RSSI_WEIGHT	AP channel RSSI multiplier. Default 100.
Survey variables	
SURVEY_SSID	SSID to broadcast in site survey mode (AP_MODE=2).
SURVEY_TX_POWER	Transmitter power in site survey mode (AP_MODE=2).
SURVEY_CH_24	Site survey transmit channel for the 2.4Ghz band (default 6).
SURVEY_CH_50	Site survey transmit channel for the 5Ghz band (default 36).
SURVEY_BEACON_INTV	Site survey beacon interval. Default 100msec.

Previously, FortiAP accepted Telnet and HTTP connection to any virtual interfaces that have an IP address. For security reasons, Telnet and HTTP access are now limited to br0 or br.vlan for AP_MGMT_VLAN_ID.

Diagnose commands include:

<code>cw_diag help</code>	Display help for all diagnose commands.
<code>cw_diag uptime</code>	Show daemon uptime.
<code>cw_diag --tlog <on off></code>	Turn on/off telnet log message.
<code>cw_diag --clog <on off></code>	Turn on/off console log message.
<code>cw_diag baudrate [9600 19200 38400 57600 115200]</code>	Set the console baud rate.

<code>cw_diag plain-ctl [0 1]</code>	Show or change current plain control setting.
<code>cw_diag sniff-cfg ip port</code>	Set sniff server ip and port.
<code>cw_diag sniff [0 1 2]</code>	Enable/disable sniff packet.
<code>cw_diag stats wl_intf</code>	Show wl_intf status.
<code>cw_diag admin-timeout [30]</code>	Set shell idle timeout in minutes.
<code>cw_diag -c wtp-cfg</code>	Show current wtp config parameters in control plane.
<code>cw_diag -c radio-cfg</code>	Show current radio config parameters in control plane.
<code>cw_diag -c vap-cfg</code>	Show current vaps in control plane.
<code>cw_diag -c ap-rogue</code>	Show rogue APs pushed by AC for on-wire scan.
<code>cw_diag -c sta-rogue</code>	Show rogue STAs pushed by AC for on-wire scan.
<code>cw_diag -c arp-req</code>	Show scanned arp requests.
<code>cw_diag -c ap-scan</code>	Show scanned APs.
<code>cw_diag -c sta-scan</code>	Show scanned STAs.
<code>cw_diag -c sta-cap</code>	Show scanned STA capabilities.
<code>cw_diag -c wids</code>	Show scanned WIDS detections.
<code>cw_diag -c darrp</code>	Show darrp radio channel.
<code>cw_diag -c mesh</code>	Show mesh status.
<code>cw_diag -c mesh-veth-acinfo</code>	Show mesh veth ac info, and mesh ether type.
<code>cw_diag -c mesh-veth-vap</code>	Show mesh veth vap.
<code>cw_diag -c mesh-veth-host</code>	Show mesh veth host.
<code>cw_diag -c mesh-ap</code>	Show mesh ap candidates.
<code>cw_diag -c scan-clr-all</code>	Flush all scanned AP/STA/ARPs.
<code>cw_diag -c ap-suppress</code>	Show suppressed APs.
<code>cw_diag -c sta-deauth</code>	De-authenticate an STA.

Link aggregation can also be set in the CLI. Link aggregation is used to combine multiple network connections in parallel in order to increase throughput beyond what a single connection could sustain.

- FortiAP 320B and 320C models are supported.
 - FortiAP 112B and 112D models **cannot** support link aggregation.
 - NPI FAP-S3xxCR and "wave2" FAP/FAP-S models will have link aggregation feature via synchronization with regular FortiAP trunk build.
-

Chapter 10 - Hardening your FortiGate

This guide describes some of the techniques used to harden (improve the security of) FortiGate devices and FortiOS.

This document contains the following sections:

- [Building security into FortiOS](#)
- [FortiOS ports and protocols](#)
- [Security best practices](#)

Building security into FortiOS

The FortiOS operating system, FortiGate hardware devices, and FortiOS virtual machines (VMs) are built with security in mind, so many security features are built into the hardware and software. Fortinet maintains an ISO:9001 certified software and hardware development processes to ensure that FortiOS and FortiGate products are developed in a secure manner.

Boot PROM and BIOS security

The boot PROM and BIOS in FortiGate hardware devices use Fortinet's own FortiBootLoader that is designed and controlled by Fortinet. FortiBootLoader is a secure, proprietary BIOS for all FortiGate appliances. FortiGate physical devices always boot from FortiBootLoader.

FortiOS kernel and user processes

FortiOS is a multi-process operating system with kernel and user processes. The FortiOS kernel runs in a privileged hardware mode while higher-level applications run in user mode. FortiOS is a closed system that does not allow the loading or execution of third-party code in the FortiOS user space. All non-essential services, packages, and applications are removed.

FortiGate appliances with SD drives are encrypted to prevent unauthorized access to data.

Administration access security

This section describes FortiOS and FortiGate administration access security features.

Admin administrator account

All FortiGate firewalls ship with a default administrator account called admin. By default, this account does not have a password. FortiOS allows administrators to add a password for this account or to remove the account and create new custom super_admin administrator accounts.

For more information, see [Rename the admin administrator account on page 1234](#).

Secure password storage

User and administrator passwords are stored securely on the system in an encrypted format. The encryption hash used for admin account passwords is SHA256/SHA1. The value that is seen in the configuration file is the Base64 encoded hash value. For example:

```
config system admin
  edit "admin"
    set accprofile "super_admin"
    set vdom "root"
    set password ENC SH2nlSm9QL9tapcHPXIqAXvX7vBJuuqu22hpa0JX0sBuKIo7z2g0Kz/+0KyH4E=
  next
end
```

Pre-shared keys in IPSec phase-1 configurations are stored in plain text. In the configuration file these pre-shared keys are encoded. The encoding consists of encrypting the password with a fixed key using DES (AES in FIPS mode) and then Base64 encoding the result.

Maintainer account

Administrators with physical access to a FortiGate appliance can use a console cable and a special administrator account called maintainer to log into the CLI. When enabled, the maintainer account can be used to log in from the console after a hard reboot. The password for the maintainer account is bcpb followed by the FortiGate serial number. An administrator has 60-seconds to complete this login. See [Resetting a lost Admin password](#) on the Fortinet Cookbook for details.

The only action the maintainer account has permissions to perform is to reset the passwords of super_admin accounts. Logging in with the maintainer account requires rebooting the FortiGate. FortiOS generates event log messages when you login with the maintainer account and for each password reset.

The maintainer account is enabled by default; however, there is an option to disable this feature. The maintainer account can be disabled using the following command:

```
config system global
  set admin-maintainer disable
end
```

If you disable this feature and lose your administrator passwords you will no longer be able to log into your FortiGate.

Administrative access security

Secure administrative access features:

- SSH, Telnet, and SNMP are disabled by default. If required, these admin services must be explicitly enabled on each interface from the GUI or CLI.
- SSHv1 is disabled by default. SSHv2 is the default version.
- SSLv3 and TLS1.0 are disabled by default. TLSv1.1 and TLSv1.2 are the SSL versions enabled by default for HTTPS admin access.
- HTTP is disabled by default, except on dedicated MGMT, DMZ, and predefined LAN interfaces. HTTP redirect to HTTPS is enabled by default.
- The `strong-crypto` global setting is enabled by default and configures FortiOS to use strong ciphers (AES, 3DES) and digest (SHA1) for HTTPS/SSH/TLS/SSL functions.
- SCP is disabled by default. Enabling SCP allows downloading the configuration file from the FortiGate as an alternative method of backing up the configuration file. To enable SCP:

```
config system global
  set admin-scp enable
end
```

- DHCP is enabled by default on the dedicated MGMT interface and on the predefined LAN port (defined on some FortiGate models).
- The default management access configuration for FortiGate models with dedicated MGMT, DMZ, WAN, and LAN interfaces is shown below. Outside of the interfaces listed below, management access must be explicitly enabled on interfaces – management services are enabled on specific interfaces and not globally.
 - Dedicated management interface
 - Ping
 - FMG-Access (fgfm)
 - CAPWAP

- HTTPS
- HTTP
- Dedicated WAN1/WAN2 interface
 - Ping
 - FMG-Access (fgfm)
- Dedicated DMZ interface
 - Ping
 - FMG-Access (fgfm)
 - CAPWAP
 - HTTPS
 - HTTP
- Dedicated LAN interface
 - Ping
 - FMG-Access (fgfm)
 - CAPWAP
 - HTTPS
 - HTTP

Network security

This section describes FortiOS and FortiGate network security features.

Network interfaces

The following are disabled by default on each FortiGate interface:

- Broadcast forwarding
- STP forwarding
- VLAN forwarding
- L2 forwarding
- Netbios forwarding
- Ident accept

For more information, see [Disable unused protocols on interfaces on page 1237](#).

TCP sequence checking

FortiOS uses TCP sequence checking to ensure a packet is part of a TCP session. By default, anti-replay protection is strict, which means that if a packet is received with sequence numbers that fall out of the expected range, FortiOS drops the packet. Strict anti-replay checking performs packet sequence checking and ICMP anti-replay checking with the following criteria:

- The SYN, FIN, and RST bit cannot appear in the same packet.
- FortiOS does not allow more than 1 ICMP error packet to go through before it receives a normal TCP or UDP packet.
- If FortiOS receives an RST packet, FortiOS checks to determine if its sequence number in the RST is within the un-ACKed data and drops the packet if the sequence number is incorrect.
- For each new session, FortiOS checks to determine if the TCP sequence number in a SYN packet has been calculated correctly and started from the correct value.

Reverse path forwarding

FortiOS implements a mechanism called Reverse Path Forwarding (RPF), or Anti Spoofing, to block an IP packet from being forwarded if its source IP does not:

- belong to a locally attached subnet (local interface), or
- be in the routing domain of the FortiGate from another source (static route, RIP, OSPF, BGP).

If those conditions are not met, FortiOS silently drops the packet.

FIPS and Common Criteria

FortiOS has received NDPP, EAL2+, and EAL4+ based FIPS and Common Criteria certifications. Common Criteria evaluations involve formal rigorous analysis and testing to examine security aspects of a product or system. Extensive testing activities involve a comprehensive and formally repeatable process, confirming that the security product functions as claimed by the manufacturer. Security weaknesses and potential vulnerabilities are specifically examined during an evaluation.

To see Fortinet's complete history of FIPS/CC certifications go to the following URL and add Fortinet to the Vendor field:

<https://csrc.nist.gov/projects/cryptographic-module-validation-program/validated-modules/search>

PSIRT advisories

The FortiGuard Labs Product Security Incident Response Team (PSIRT) continually tests and gathers information about Fortinet hardware and software products, looking for vulnerabilities and weaknesses. Any such findings are fed back to Fortinet's development teams and serious issues are described along with protective solutions. The PSIRT regulatory releases PSIRT advisories when issues are found and corrected. Advisories are listed at <https://www.fortiguard.com/psirt>.

FortiOS ports and protocols

Communication to and from FortiOS is strictly controlled and only selected ports are opened for supported functionality such as administrator logins and communication with other Fortinet products or services.

Accessing FortiOS using an open port is protected by authentication, identification, and encryption requirements. As well, ports are only open if the feature using them is enabled.

FortiOS open ports

The following diagram and tables shows the incoming and outgoing ports that are potentially opened by FortiOS. For more details about open ports and the communication protocols that FortiOS uses, see the document [Fortinet Communication Ports and Protocols](#).

(missing or bad snippet)

Closing open ports

You can close open ports by disabling the feature that opens them. For example, if FortiOS is not managing a FortiAP then the CAPWAP feature for managing FortiAPs can be disabled, closing the CAPWAP port.

The following sections of this document described a number of options for closing open ports:

- [Use local-in policies to close open ports or restrict access on page 1238](#)
- [Disable unused protocols on interfaces on page 1237](#)

Security best practices

This chapter describes some techniques and best practices that you can use to improve FortiOS security.

Install the FortiGate unit in a physically secure location

A good place to start with is physical security. Install your FortiGate in a secure location, such as a locked room or one with restricted access. A restricted location prevents unauthorized users from getting physical access to the device.

If unauthorized users have physical access, they can disrupt your entire network by disconnecting your FortiGate (either by accident or on purpose). They could also connect a console cable and attempt to log into the CLI. Also, when a FortiGate unit reboots, a person with physical access can interrupt the boot process and install different firmware.

Register your product with Fortinet Support

You need to register your Fortinet product with Fortinet Support to receive customer services, such as firmware updates and customer support. You must also register your product for FortiGuard services, such as up-to-date antivirus and IPS signatures. To register your product the [Fortinet Support](#) website.

Keep your FortiOS firmware up to date

Always keep FortiOS up to date. The most recent version is the most stable and has the most bugs fixed and vulnerabilities removed. Fortinet periodically updates the FortiGate firmware to include new features and resolve important issues.

After you register your FortiGate, you can receive notifications on FortiGate GUI about firmware updates. You can update the firmware directly from the GUI or by downloading firmware updates from the [Fortinet Support](#) website.

Before you install any new firmware, be sure to follow these steps:

- Review the release notes for the latest firmware release.
- Review the [Supported Upgrade Paths](#) guide to determine the best path to take from your current version of FortiOS to the latest version.
- Back up the current configuration.

Only FortiGate administrators who have read and write privileges can upgrade the FortiOS firmware.

System administrator best practices

This section describes a collection of changes you can implement to make administrative access to the GUI and CLI more secure.

Disable administrative access to the external (Internet-facing) interface

When possible, don't allow administration access on the external (Internet-facing) interface.

To disable administrative access, go to **Network > Interfaces**, edit the external interface and disable HTTPS, PING, HTTP, SSH, and TELNET under **Administrative Access**.

From the CLI:

```
config system interface
  edit <external-interface-name>
    unset allowaccess
  end
```

Allow only HTTPS access to the GUI and SSH access to the CLI

For greater security never allow HTTP or Telnet administrative access to a FortiGate interface, only allow HTTPS and SSH access. You can change these settings for individual interfaces by going to **Network > Interfaces** and adjusting the administrative access to each interface.

From the CLI:

```
config system interface
  edit <interface-name>
    set allowaccess https ssh
  end
```

Require TLS 1.2 for HTTPS administrator access

Use the following command to require TLS 1.2 for HTTPS administrator access to the GUI:

```
config system global
  set admin-https-ssl-versions tlsv1-2
end
```

TLS 1.2 is currently the most secure SSL/TLS supported version for SSL-encrypted administrator access.

Re-direct HTTP GUI logins to HTTPS

Go to **System > Settings > Administrator Settings** and enable **Redirect to HTTPS** to make sure that all attempted HTTP login connections are redirected to HTTPS.

From the CLI:

```
config system global
  set admin-https-redirect enable
end
```

Change the HTTPS and SSH admin access ports to non-standard ports

Go to **System > Settings > Administrator Settings** and change the HTTPS and SSH ports.

You can change the default port configurations for HTTPS and SSH administrative access for added security. To connect to a non-standard port, the new port number must be included in the collection request. For example:

- If you change the HTTPS port to 7734, you would browse to `https://<ip-address>:7734`.
- If you change the SSH port to 2345, you would connect to `ssh admin@<ip-address>:2345`

To change the HTTPS and SSH login ports from the CLI:

```
config system global
  set admin-sport 7734
  set admin-ssh-port 2345
end
```

If you change to the HTTPS or SSH port numbers, make sure your changes do not conflict with ports used for other services.

Maintain short login timeouts

Set the idle timeout to a short time to avoid the possibility of an administrator walking away from their management computer and leaving it exposed to unauthorized personnel.

To set the administrator idle timeout, go to **System > Settings** and enter the amount of time for the **Idle timeout**. A best practice is to keep the default time of 5 minutes.

To set the administrator idle timeout from the CLI:

```
config system global
    set admintimeout 5
end
```

You can use the following command to adjust the grace time permitted between making an SSH connection and authenticating. The range can be between 10 and 3600 seconds, the default is 120 seconds (minutes). By shortening this time, you can decrease the chances of someone attempting a brute force attack from being successful. For example, you could set the time to 30 seconds.

```
config system global
    set admin-ssh-grace-time 30
end
```

Restrict logins from trusted hosts

Setting up trusted hosts for an administrator limits the addresses from where they can log into FortiOS. The trusted hosts configuration applies to most forms of administrative access including HTTPS, SSH, and SNMP. When you identify a trusted host for an administrator account, FortiOS accepts that administrator's login only from one of the trusted hosts. A login, even with proper credentials, from a non-trusted host is dropped.

Even if you have configured trusted hosts, if you have enabled ping administrative access on a FortiGate interface, it will respond to ping requests from any IP address.

To identify trusted hosts, go to **System > Administrators**, edit the administrator account, enable **Restrict login to trusted hosts**, and add up to ten trusted host IP addresses.

To add two trusted hosts from the CLI:

```
config system admin
    edit <administrator-name>
        set trustedhost1 172.25.176.23 255.255.255.255
        set trustedhost2 172.25.177.0 255.255.255.0
    end
```

Trusted host IP addresses can identify individual hosts or subnets. Just like firewall policies, FortiOS searches through the list of trusted hosts in order and acts on the first match it finds. When you configure trusted hosts, start by adding specific addresses at the top of the list. Follow with more general IP addresses. You don't have to add addresses to all of the trusted hosts as long as all specific addresses are above all of the 0.0.0.0 0.0.0.0 addresses.

Set up two-factor authentication for administrators

FortiOS supports FortiToken and FortiToken Mobile 2-factor authentication. FortiToken Mobile is available for iOS and Android devices from their respective application stores.

Every registered FortiGate unit includes two trial tokens for free. You can purchase additional tokens from your reseller or from Fortinet.

To assign a token to an administrator, go to **System > Administrators** and select **Enable Two-factor Authentication** for each administrator.

Create multiple administrator accounts

Rather than allowing all administrators to access FortiOS with the same administrator account, you can create accounts for each person or each role that requires administrative access. This configuration allows you to track the activities of each administrator or administrative role.

If you want administrators to have different functions you can add different administrator profiles. Go to **System > Admin Profiles** and select **Create New**.

Modify administrator account lockout duration and threshold values

By default, the FortiGate sets the number of password retries at three, allowing the administrator a maximum of three attempts to log into their account before locking the account for a set amount of time.

Both the number of attempts (`admin-lockout-threshold`) and the wait time before the administrator can try to enter a password again (`admin-lockout-duration`) can be configured within the CLI.

To configure the lockout options:

```
config system global
  set admin-lockout-threshold <failed_attempts>
  set admin-lockout-duration <seconds>
end
```

The default value of `admin-lockout-threshold` is 3 and the range of values is between 1 and 10. The `admin-lockout-duration` is set to 60 seconds by default and the range of values is between 1 and 4294967295 seconds.

Keep in mind that the higher the lockout threshold, the higher the risk that someone may be able to break into the FortiGate.

Example:

To set the `admin-lockout-threshold` to one attempt and the `admin-lockout-duration` to a five minute duration before the administrator can try to log in again, enter the commands:

```
config system global
  set admin-lockout-threshold 1
  set admin-lockout-duration 300
end
```

If the time span between the first failed login attempt and the `admin-lockout-threshold` failed login attempt is less than `admin-lockout-duration`, the lockout will be triggered.

Rename the admin administrator account

You can improve security by renaming the admin account. To do this, create a new administrator account with the `super_admin` admin profile and log in as that administrator. Then go to **System > Administrators** and edit the admin administrator and change the **User Name**. Renaming the admin account makes it more difficult for an attacker to log into FortiOS.

Add administrator disclaimers

FortiOS can display a disclaimer before or after logging into the GUI or CLI (or both). In either case the administrator must read and accept the disclaimer before they can proceed.

Use the following command to display a disclaimer before logging in:

```
config system global
  set pre-login-banner enable
end
```

Use the following command to display a disclaimer after logging in:

```
config system global
  set post-login-banner enable
end
```

You can customize the replacement messages for these disclaimers by going to **System > Replacement Messages**. Select **Extended View** to view and edit the **Administrator** replacement messages.

From the CLI:

```
config system replacemsg admin pre_admin-disclaimer-text
config system replacemsg admin post_admin-disclaimer-text
```

Global commands for stronger and more secure encryption

This section describes some best practices for employing stronger and more secure encryption.

Turn on global strong encryption

Enter the following command to configure FortiOS to use only strong encryption and allow only strong ciphers (AES, 3DES) and digest (SHA1) for HTTPS, SSH, TLS, and SSL functions.

```
config sys global
  set strong-crypto enable
end
```

Disable MD5 and CBC for SSH

In some cases, you may not be able to enable strong encryption. For example, your FortiGate may be communicating with a system that does not support strong encryption. With `strong-crypto` disabled you can use the following options to prevent SSH sessions with the FortiGate from using less secure MD5 and CBC algorithms:

```
config sys global
  set ssh-hmac-md5 disable
  set ssh-cbc-cipher disable
end
```

Disable static keys for TLS

You can use the following command to prevent TLS sessions from using static keys (AES128-SHA, AES256-SHA, AES128-SHA256, AES256-SHA256):

```
config sys global
    set ssl-static-key-ciphers disable
end
```

Require larger values for Diffie-Hellman exchanges

Larger Diffie-Hellman values result in stronger encryption. Use the following command to force Diffie-Hellman exchanges to use 8192 bit values (the highest configurable DH value).

```
config sys global
    set dh-params 8192
end
```

Disable sending malware statistics to FortiGuard

By default FortiOS periodically sends encrypted malware statistics to FortiGuard. The malware statistics record Antivirus, IPS, or Application Control events. This data is used to improved FortiGuard services. The malware statistics that FortiOS sends do not include any personal or sensitive customer data. The information is not shared with any external parties and is used in accordance with Fortinet's [Privacy Policy](#).

To disable sending malware statistics to FortiGuard, enter the following command:

```
config system global
    set fds-statistics disable
end
```

Disable sending Security Rating statistics to FortiGuard

Security Rating is a Fortinet Security Fabric feature that allows customers to audit their Security Fabric and find and fix security problems. As part of the feature, FortiOS sends your security rating to FortiGuard every time a security rating test runs.

You can opt out of submitting Security Rating scores to FortiGuard. If you opt out you won't be able to see how your organization's scores compare with the scores of other organizations. Instead, an absolute score is shown. Use the following command to disable FortiGuard Security Rating result submission:

```
config system global
    set fortiguard-audit-result-submission disable
end
```

Disable auto USB installation

If USB installation is enabled, an attacker with physical access to a FortiGate could load a new configuration or firmware on the FortiGate using the USB port. You can disable USB installation by entering the following from the CLI:

```
config system auto-install
    set auto-install-config disable
    set auto-install-image disable
end
```

Set system time by synchronizing with an NTP server

For accurate time, use an NTP server to set system time. Synchronized time facilitates auditing and consistency between expiry dates used in expiration of certificates and security protocols.

From the GUI go to **System > Settings > System Time** and select **Synchronize with NTP Server**. By default, this causes FortiOS to synchronize with Fortinet's FortiGuard secure NTP server.

From the CLI you can use one or more different NTP servers:

```
config system ntp
  set type custom
  set ntpsync enable
  config ntpserver
    edit 1
      set server <ntp-server-ip>
    next
    edit 2
      set server <other-ntp-server-ip>
  end
```

Disable the maintainer admin account

Administrators with physical access to a FortiGate appliance can use a console cable and a special administrator account called maintainer to log into the CLI without a password. This feature allows you to log into a FortiGate if you have lost all administrator passwords. See [Resetting a lost Admin password](#) on the Fortinet Cookbook for details.

The maintainer account can be disabled using the following command:

```
config system global
  set admin-maintainer disable
end
```

If you disable this feature and lose your administrator passwords you will no longer be able to log into your FortiGate.

Enable password policies

Go to **System > Settings > Password Policy**, to create a password policy that all administrators must follow. Using the available options you can define the required length of the password, what it must contain (numbers, upper and lower case, and so on) and an expiry time.

Use the password policy feature to make sure all administrators use secure passwords that meet your organization's requirements.

Configure auditing and logging

For optimum security go to **Log & Report > Log Settings** enable **Event Logging**. For best results send log messages to FortiAnalyzer or FortiCloud.

From FortiAnalyzer or FortiCloud, you can view reports or system event log messages to look for system events that may indicate potential problems. You can also view system events by going to **FortiView > System Events**.

Establish an auditing schedule to routinely inspect logs for signs of intrusion and probing.

Encrypt logs sent to FortiAnalyzer/FortiManager

To keep information in log messages sent to FortiAnalyzer private, go to **Log & Report > Log Settings** and when you configure Remote Logging to FortiAnalyzer/FortiManager select **Encrypt log transmission**.

From the CLI.

```
config log {fortianalyzer | fortianalyzer2 | fortianalyzer3} setting
  set enc-algorithm high
end
```

Disable unused interfaces

To disable an interface from the GUI, go to **Network > Interfaces**. Edit the interface to be disabled and set **Interface State** to **Disabled**.

From the CLI, to disable the port21 interface:

```
config system interface
  edit port21
    set status down
  end
```

Disable unused protocols on interfaces

You can use the `config system interface` command to disable unused protocols that attackers may attempt to use to gather information about a FortiGate unit. Many of these protocols are disabled by default. Using the `config system interface` command you can see the current configuration of each of these options for the selected interface and then choose to disable them if required.

```
config system interface
  edit <interface-name>
    set dhcp-relay-service disable
    set pptp-client disable
    set arpforward disable
    set broadcast-forward disable
    set l2forward disable
    set icmp-redirect disable
    set vlanforward disable
    set stpforward disable
    set ident-accept disable
    set ipmac disable
    set netbios-forward disable
    set security-mode none
    set device-identification disable
    set lldp-transmission disable
  end
```

Option	Description
dhcp-relay-service	Disable the DHCP relay service.
pptp-client	Disable operating the interface as a PPTP client.
arpforward	Disable ARP forwarding.
broadcast-forward	Disable forwarding broadcast packets.
l2forward	Disable layer 2 forwarding.
icmp-redirect	Disable ICMP redirect.
vlanforward	Disable VLAN forwarding.
stpforward	Disable STP forwarding.
ident-accept	Disable authentication for this interface. The interface will not respond to a connection with an authentication prompt.
ipmac	Disable IP/MAC binding.
netbios-forward	Disable NETBIOS forwarding.
security-mode	Set to <code>none</code> to disable captive portal authentication. The interface will not respond to a connection with a captive portal.
device-identification	Disable device identification.
lldp-transmission	Disable link layer discovery (LLDP).

Use local-in policies to close open ports or restrict access

You can also use local-in policies to close open ports or otherwise restrict access to FortiOS.

Close ICMP ports

Use the following command to close all ICMP ports on the WAN1 interface. The following example blocks traffic that matches the ICMP_ANY firewall service.

```
config firewall local-in-policy
  edit 1
    set intf wan1
    set srcaddr all
    set dstaddr all
    set action deny
    set service ICMP_ANY
    set schedule always
  end
```

Close the BGP port

Use the following command to close the BGP port on the wan1 interface. The following example blocks traffic that matches the BGP firewall service.

```
config firewall local-in-policy
  edit 1
    set intf wan1
    set srcaddr all
    set dstaddr all
    set action deny
    set service BGP
    set schedule always
  end
```

Chapter 11 - Hardware Acceleration

This FortiOS Handbook chapter contains the following sections:

[Hardware acceleration overview](#) describes the capabilities of FortiGate content processors (CPs), security processors (SPs) and network processors (NPs). This chapter also describes how to determine the hardware acceleration components installed in your FortiGate unit and contains some configuration details and examples.

[NP6 and NP6lite acceleration](#) describes the FortiGate NP6 network processor.

[FortiGate NP6 architectures](#) contains details about the network processing architectures of FortiGate units that contain NP6 processors.

[FortiGate NP6lite architectures on page 1326](#) contains details about the network processing architectures of FortiGate units that contain NP6Lite processors.

[NP4 and NP4Lite acceleration](#) describes the FortiGate NP4 network processor.

[FortiGate NP4 architectures](#) contains details about the network processing architectures of FortiGate units that contain NP4 processors.

What's new in FortiOS 6.0.2

The following list contains new Hardware Acceleration features added in FortiOS 6.0.2. Click on a link to navigate to that section for further information.

- Per-session accounting for NP6Lite processors, see [Enabling per-session accounting for offloaded NP6 and NP6lite sessions on page 1271](#).

What's new in FortiOS 6.0

The following list contains new Hardware Acceleration features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- New options for optimizing FortiGate-3960E and 3980E IPsec VPN performance, see [Optimizing FortiGate-3960E and 3980E IPsec VPN performance on page 1275](#).

Hardware acceleration overview

Most FortiGate models have specialized acceleration hardware, (called Security Processing Units (SPUs)) that can offload resource intensive processing from main processing (CPU) resources. Most FortiGate units include specialized content processors (CPs) that accelerate a wide range of important security processes such as virus scanning, attack detection, encryption and decryption. (Only selected entry-level FortiGate models do not include a CP processor.) Many FortiGate models also contain security processors (SPs) that accelerate processing for specific security features such as IPS and network processors (NPs) that offload processing of high volume network traffic.

Content processors (CP4, CP5, CP6, CP8, and CP9)

Most FortiGate models contain Security Processing Unit (SPU) Content Processors (CPs) that accelerate many common resource intensive security related processes. CPs work at the system level with tasks being offloaded to them as determined by the main CPU. Capabilities of the CPs vary by model. Newer FortiGate units include CP8 and CP9 processors. Older CP versions still in use in currently operating FortiGate models include the CP4, CP5, and CP6.

CP9 capabilities

The CP9 content processor provides the following services:

- Flow-based inspection (IPS, application control etc.) pattern matching acceleration with over 10Gbps throughput
 - IPS pre-scan
 - IPS signature correlation
 - Full match processors
- High performance VPN bulk data engine
 - IPsec and SSL/TLS protocol processor
 - DES/3DES/AES128/192/256 in accordance with FIPS46-3/FIPS81/FIPS197
 - MD5/SHA-1/SHA256/384/512-96/128/192/256 with RFC1321 and FIPS180
 - HMAC in accordance with RFC2104/2403/2404 and FIPS198
 - ESN mode
 - GCM support for NSA "Suite B" (RFC6379/RFC6460) including GCM-128/256; GMAC-128/256
- Key Exchange Processor that supports high performance IKE and RSA computation
 - Public key exponentiation engine with hardware CRT support
 - Primary checking for RSA key generation
 - Handshake accelerator with automatic key material generation
 - True Random Number generator
 - Elliptic Curve support for NSA "Suite B"
 - Sub public key engine (PKCE) to support up to 4096 bit operation directly (4k for DH and 8k for RSA with CRT)
- DLP fingerprint support
 - TTTD (Two-Thresholds-Two-Divisors) content chunking
 - Two thresholds and two divisors are configurable

CP8 capabilities

The CP8 content processor provides the following services:

- Flow-based inspection (IPS, application control etc.) pattern matching acceleration
- High performance VPN bulk data engine
 - IPsec and SSL/TLS protocol processor
 - DES/3DES/AES in accordance with FIPS46-3/FIPS81/FIPS197
 - ARC4 in compliance with RC4
 - MD5/SHA-1/SHA256 with RFC1321 and FIPS180
 - HMAC in accordance with RFC2104/2403/2404 and FIPS198
- Key Exchange Processor support high performance IKE and RSA computation
 - Public key exponentiation engine with hardware CRT support
 - Primarily checking for RSA key generation
 - Handshake accelerator with automatic key material generation
 - Random Number generator compliance with ANSI X9.31
 - Sub public key engine (PKCE) to support up to 4096 bit operation directly
- Message authentication module offers high performance cryptographic engine for calculating SHA256/SHA1/MD5 of data up to 4G bytes (used by many applications)
- PCI express Gen 2 four lanes interface
- Cascade Interface for chip expansion

CP6 capabilities

- Dual content processors
- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC with RFC1321 and FIPS180
- HMAC in accordance with RFC2104/2403/2404 and FIPS198
- IPsec protocol processor
- High performance IPsec engine
- Random Number generator compliance with ANSI X9.31
- Key exchange processor for high performance IKE and RSA computation
- Script Processor
- SSL/TLS protocol processor for SSL content scanning and SSL acceleration

CP5 capabilities

- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC with RFC1321/2104/2403/2404 and FIPS180/FIPS198
- IPsec protocol processor
- High performance IPsec Engine
- Random Number generator compliant with ANSI X9.31
- Public Key Crypto Engine supports high performance IKE and RSA computation
- Script Processor

CP4 capabilities

- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC
- IPsec protocol processor
- Random Number generator
- Public Key Crypto Engine
- Content processing engine
- ANSI X9.31 and PKCS#1 certificate support

Determining the content processor in your FortiGate unit

Use the `get hardware status` CLI command to determine which content processor your FortiGate unit contains. The output looks like this:

```
get hardware status
Model name: FortiGate-100D
ASIC version: CP8
ASIC SRAM: 64M
CPU: Intel(R) Atom(TM) CPU D525 @ 1.80GHz
Number of CPUs: 4
RAM: 1977 MB
Compact Flash: 15331 MB /dev/sda
Hard disk: 15272 MB /dev/sda
USB Flash: not available
Network Card chipset: Intel(R) PRO/1000 Network Connection (rev.0000)
Network Card chipset: bcm-sw Ethernet driver 1.0 (rev.)
```

The ASIC version line lists the content processor model number.

Viewing SSL acceleration status

You can view the status of SSL acceleration using the following command:

```
get vpn status ssl hw-acceleration-status
Acceleration hardware detected: kxp=on cipher=on
```

Where kxp means key exchange acceleration.

Disabling CP offloading for firewall policies

If you want to completely disable offloading to CP processors for test purposes or other reasons, you can do so in security policies. Here are some examples:

For IPv4 security policies.

```
config firewall policy
edit 1
set auto-asic-offload disable
end
```

For IPv6 security policies.

```
config firewall policy6
edit 1
set auto-asic-offload disable
end
```

For multicast security policies.

```
config firewall multicast-policy
edit 1
set auto-asic-offload disable
end
```

Disabling `auto-asic-offload` also disables NP offloading.

Security processors (SPs)

FortiGate Security Processing (SP) modules, such as the SP3 but also including the XLP, XG2, XE2, FE8, and CE4, work at both the interface and system level to increase overall system performance by accelerating specialized security processing. You can configure the SP to favor IPS over firewall processing in hostile high-traffic environments.

SP processors include their own IPS engine which is similar to the FortiOS IPS engine but with the following limitations:

- The SP IPS engine does not support SSL deep inspection. When you have SSL deep inspection enabled for a security policy that includes flow-based inspection or IPS, offloading to the SP is disabled and traffic is processed by the FortiGate CPU and CP processors.
- The SP IPS engine does not support FortiGuard Web Filtering. When you enable flow-based FortiGuard Web Filtering on a FortiGate unit with an SP processor, the SP processor cannot perform FortiGuard lookups and web pages fail to load.

The following security processors are available:

- The SP3 (XLP) is built into the FortiGate-5101B and provides IPS acceleration. No special configuration is required. All IPS processing, including traffic accepted by IPv4 and IPv6 traffic policies and IPv4 and IPv6 DoS policies is accelerated by the built-in SP3 processors.
- The FMC-XG2 is an FMC module with two 10Gb/s SPF+ interfaces that can be used on FortiGate-3950B and FortiGate-3951B units.
- The FortiGate-3140B also contains a built-in XG2 using ports 19 and 20.
- The ADM-XE2 is a dual-width AMC module with two 10Gb/s interfaces that can be used on FortiGate-3810A and FortiGate-5001A-DW systems.
- The ADM-FE8 is a dual-width AMC module with eight 1Gb/s interfaces that can be used with the FortiGate-3810A.
- The ASM-CE4 is a single-width AMC module with four 10/100/1000 Mb/s interfaces that can be used on FortiGate-3016B and FortiGate-3810A units.

Traffic is blocked if you enable IPS for traffic passing over inter-VDOM links if that traffic is being offloaded by an SP processor. If you disable SP offloading, traffic will be allowed to flow. You can disable offloading in individual firewall policies by disabling `auto-asic-offload` for those policies. You can also use the following command to disable all IPS offloading:

```
config ips global
set np-accel-mode none
set cp-accel-mode none
end
```

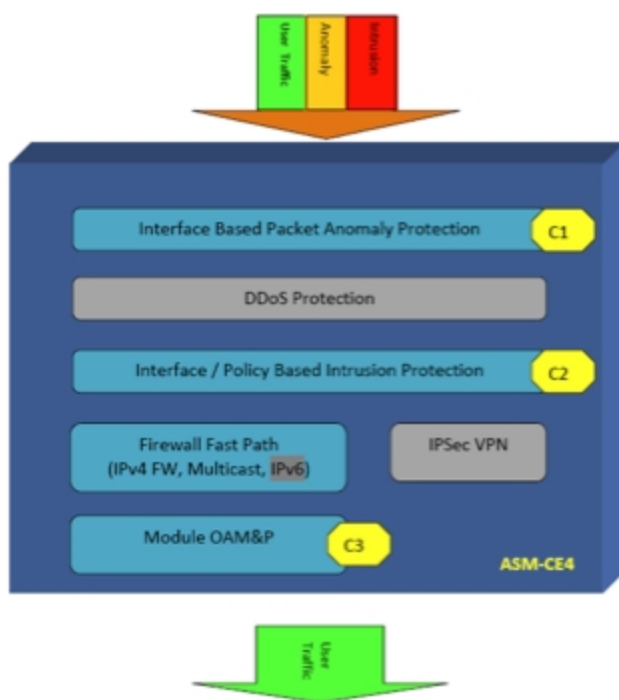

SP processing flow

SP processors provide an integrated high performance fast path multilayer solution for both intrusion protection and firewall functions. The multilayered protection starts from anomaly checking at packet level to ensure each packet is sound and reasonable. Immediately after that, a sophisticated set of interface based packet anomaly protection, DDoS protection, policy based intrusion protection, firewall fast path, and behavior based methods are employed to prevent DDoS attacks from the rest of system.

Then the packets enter an interface/policy based intrusion protection system,

where each packet is evaluated against a set of signatures. The end result is streams of user packets that are free of anomaly and attacks, entering the fast path system for unicast or multicast fast path forwarding.

SP processing flow

Displaying information about security processing modules

You can display information about installed SP modules using the CLI command

```
diagnose npu spm
```

For example, for the FortiGate-5101C:

```
FG-5101C # diagnose npu spm list
Available SP Modules:
```

ID	Model	Slot	Interface
0	xh0	built-in	port1, port2, port3, port4, base1, base2, fabric1, fabric2 eth10, eth11, eth12, eth13 eth14, eth15, eth16, eth17 eth18, eth19

You can also use this command to get more info about SP processing. This example shows how to display details about how the module is processing sessions using the syn proxy.

```
diagnose npu spm dos synproxy <sp_id>
```

This is a partial output of the command:

```
Number of proxied TCP connections : 0
Number of working proxied TCP connections : 0
Number of retired TCP connections : 0
Number of valid TCP connections : 0
Number of attacks, no ACK from client : 0
Number of no SYN-ACK from server : 0
Number of reset by server (service not supported): 0
Number of established session timeout : 0
Client timeout setting : 3 Seconds
Server timeout setting : 3 Seconds
```

Network processors (NP1, NP2, NP3, NP4, NP4Lite, NP6 and NP6Lite)

FortiASIC network processors work at the interface level to accelerate traffic by offloading traffic from the main CPU. Current models contain NP4, NP4Lite, NP6, and NP6lite network processors. Older FortiGate models include NP1 network processors (also known as FortiAccel, or FA2) and NP2 network processors.

The traffic that can be offloaded, maximum throughput, and number of network interfaces supported by each varies by processor model:

- NP6 supports offloading of most IPv4 and IPv6 traffic, IPsec VPN encryption, CAPWAP traffic, and multicast traffic. The NP6 has a maximum throughput of 40 Gbps using 4 x 10 Gbps XAUI or Quad Serial Gigabit Media Independent Interface (QSGMII) interfaces or 3 x 10 Gbps and 16 x 1 Gbps XAUI or QSGMII interfaces. For details about the NP6 processor, see [NP6 and NP6lite acceleration on page 1255](#) and for information about FortiGate models with NP6 processors, see [FortiGate NP6 architectures on page 1276](#).
- NP6lite is similar to the NP6 but with a lower throughput and some functional limitations (for example, the NP6lite does not offload CAPWAP traffic). The NP6lite has a maximum throughput of 10 Gbps using 2x QSGMII and 2x Reduced gigabit media-independent interface (RGMII) interfaces. For details about the NP6 processor, see [NP6Lite processors on page 1257](#) and for information about FortiGate models with NP6 processors, see [FortiGate NP6lite architectures on page 1326](#).
- NP4 supports offloading of most IPv4 firewall traffic and IPsec VPN encryption. The NP4 has a capacity of 20 Gbps through 2 x 10 Gbps interfaces. For details about NP4 processors, see [NP4 and NP4Lite acceleration on page 1328](#) and for information about FortiGate models with NP4 processors, see [FortiGate NP4 architectures on page 1339](#).
- NP4lite is similar to the NP4 but with a lower throughput (but with about half the performance) and some functional limitations.
- NP2 supports IPv4 firewall and IPsec VPN acceleration. The NP2 has a capacity of 2 Gbps through 2 x 10 Gbps interfaces or 4 x 1 Gbps interfaces.
- NP1 supports IPv4 firewall and IPsec VPN acceleration with 2 Gbps capacity. The NP1 has a capacity of 2 Gbps through 2 x 1 Gbps interfaces.
 - The NP1 does not support frames greater than 1500 bytes. If your network uses jumbo frames, you may need to adjust the MTU (Maximum Transmission Unit) of devices connected to NP1 ports. Maximum frame size for NP2, NP4, and NP6 processors is 9216 bytes.
 - For both NP1 and NP2 network processors, ports attached to a network processor cannot be used for firmware installation by TFTP.

Sessions that require proxy-based security features (for example, virus scanning, IPS, application control and so on) are not fast pathed and must be processed by the CPU. Sessions that require flow-based security features can be offloaded to NP4 or NP6 network processors if the FortiGate supports NTurbo.

Determining the network processors installed in your FortiGate

Use either of the following command to list the NP6 processors in your FortiGate unit:

```
get hardware npu np6 port-list
diagnose npu np6 port-list
```

Use either of the following command to list the NP6lite processors in your FortiGate unit:

```
get hardware npu np6lite port-list
diagnose npu np6lite port-list
```

To list other network processors on your FortiGate unit, use the following CLI command.

```
get hardware npu <model> list
<model> can be legacy, np1, np2 or np4.
```

The output lists the interfaces that have the specified processor. For example, for a FortiGate-5001B:

```
get hardware npu np4 list
ID      Model      Slot      Interface
0       On-board          port1 port2 port3 port4
        fabric1 base1 npu0-vlink0 npu0-vlink1
1       On-board          port5 port6 port7 port8
        fabric2 base2 npu1-vlink0 npu1-vlink1
```

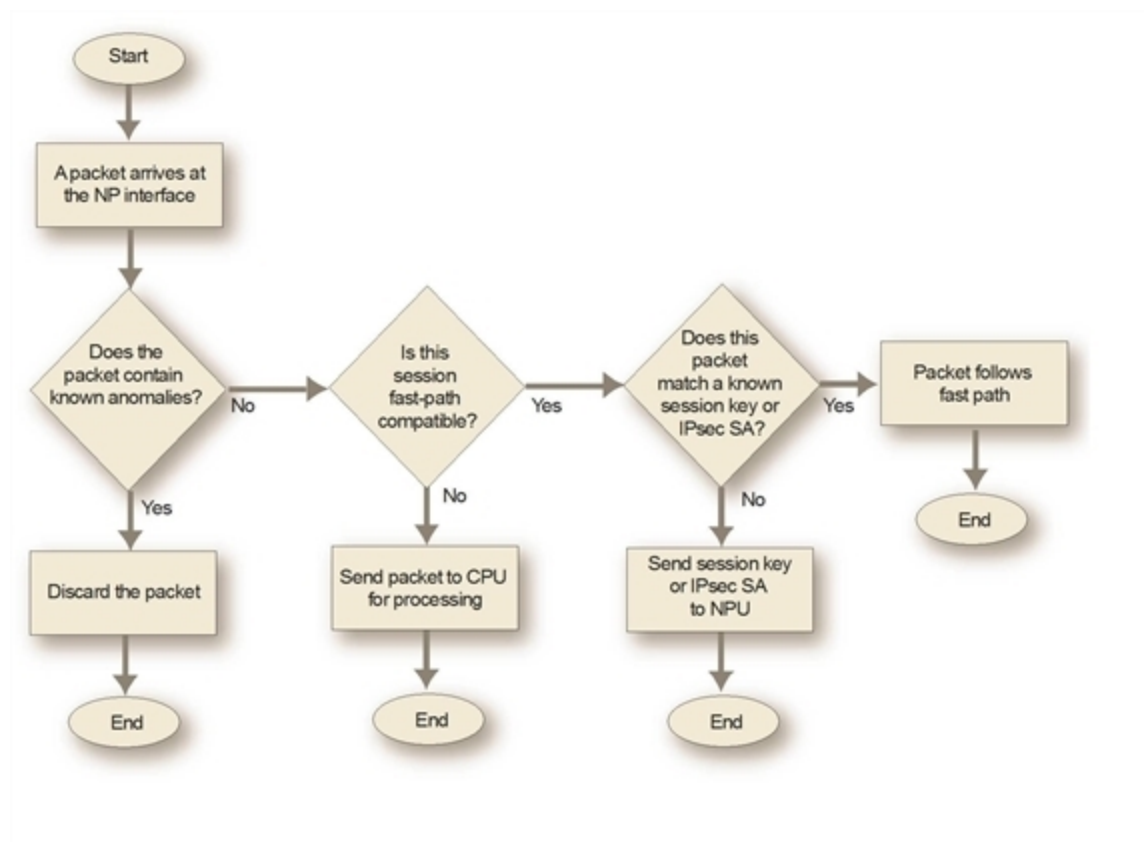

The npu0-vlink0, npu1-vlink1 etc interfaces are used for accelerating inter-VDOM links.

How NP hardware acceleration alters packet flow

NP hardware acceleration generally alters packet flow as follows:

1. Packets initiating a session pass to the FortiGate unit's main processing resources (CPU).
2. The FortiGate unit assesses whether the session matches fast path (offload) requirements. To be suitable for offloading, traffic must possess only characteristics that can be processed by the fast path. The list of requirements depends on the processor, see [NP6 session fast path requirements on page 1256](#) or [NP4 session fast path requirements on page 1329](#). If the session can be fast pathed, the FortiGate unit sends the session key or IPsec security association (SA) and configured firewall processing action to the appropriate network processor.
3. Network processors continuously match packets arriving on their attached ports against the session keys and SAs they have received.
 - If a network processor's network interface is configured to perform hardware accelerated anomaly checks, the network processor drops or accepts packets that match the configured anomaly patterns. These checks are separate from and in advance of anomaly checks performed by IPS, which is not compatible with network processor offloading. See [Offloading NP4 anomaly detection on page 1336](#).
 - The network processor next checks for a matching session key or SA. If a matching session key or SA is found, and if the packet meets packet requirements, the network processor processes the packet according to the configured action and then sends the resulting packet. This is the actual offloading step. Performing this processing on the NP processor improves overall performance because the NP processor is optimized for this task. As well, overall FortiGate performance is improved because the CPU has fewer sessions to process.

NP network processor packet flow

- If a matching session key or SA is not found, or if the packet does not meet packet requirements, the packet cannot be offloaded. The network processor sends the data to the FortiGate unit's CPU, which processes the packet.

Encryption and decryption of IPsec traffic originating from the FortiGate can utilize network processor encryption capabilities.

Packet forwarding rates vary by the percentage of offloadable processing and the type of network processing required by your configuration, but are independent of frame size. For optimal traffic types, network throughput can equal wire speed.

NP processors and traffic logging and monitoring

Except for the NP6, network processors do not count offloaded packets, and offloaded packets are not logged by traffic logging and are not included in traffic statistics and traffic log reports.

NP6 processors support per-session traffic and byte counters, Ethernet MIB matching, and reporting through messages resulting in traffic statistics and traffic log reporting.

Accelerated sessions on FortiView All Sessions page

When viewing sessions in the FortiView All Sessions console, NP4/ NP6 accelerated sessions are highlighted with an NP4 or NP6 icon. The tooltip for the icon includes the NP processor type and the total number of accelerated sessions.

You can also configure filtering to display FortiASIC sessions.

NP session offloading in HA active-active configuration

Network processors can improve network performance in active-active (load balancing) high availability (HA) configurations, even though traffic deviates from general offloading patterns, involving more than one network processor, each in a separate FortiGate unit. No additional offloading requirements apply.

Once the primary FortiGate unit's main processing resources send a session key to its network processor(s), network processor(s) on the primary unit can redirect any subsequent session traffic to other cluster members, reducing traffic redirection load on the primary unit's main processing resources.

As subordinate units receive redirected traffic, each network processor in the cluster assesses and processes session offloading independently from the primary unit. Session key states of each network processor are not part of synchronization traffic between HA members.

Configuring NP HMAC check offloading

Hash-based Message Authentication Code (HMAC) checks offloaded to network processors by default. You can enter the following command to disable this feature:

```
configure system global
    set ipsec-hmac-offload disable
end
```

Software switch interfaces and NP processors

FortiOS supports creating a software switch by grouping two or more FortiGate physical interfaces into a single virtual or software switch interface. All of the interfaces in this virtual switch act like interfaces in a hardware switch in that they all have the same IP address and can be connected to the same network. You create a software switch interface from the CLI using the command `config system switch-interface`.

The software switch is a bridge group of several interfaces, and the FortiGate CPU maintains the mac-port table for this bridge. As a result of this CPU involvement, traffic processed by a software switch interface is not offloaded to network processors.

Disabling NP acceleration for individual IPsec VPN phase 1s

Use the following command to disable NP offloading for an interface-based IPsec VPN phase 1:

```
config vpn ipsec phase1-interface
    edit phase-1-name
        set npu-offload disable
    end
```

Use the following command to disable NP offloading for a policy-based IPsec VPN phase 1:

```
config vpn ipsec phase1
    edit phase-1-name
        set npu-offload disable
    end
```

The `npu-offload` option is enabled by default.

Disabling NP offloading for unsupported IPsec encryption or authentication algorithms

In general, more recent IPsec VPN encryption and authentication algorithms may not be supported by older NP processors. For example, NP4 network processors do not support SHA-256, SHA-384, and SHA-512. IPsec traffic with unsupported algorithms is not offloaded and instead is processed by the FortiGate CPU. In addition, this

configuration may cause packet loss and other performance issues. If you experience packet loss or performance problems you should set the `npu-offload` option to `disable`. Future FortiOS versions should prevent selecting algorithms not supported by the hardware.

Disabling NP offloading for firewall policies

Use the following options to disable NP offloading for specific security policies:

For IPv4 security policies.

```
config firewall policy
  edit 1
    set auto-asic-offload disable
  end
```

For IPv6 security policies.

```
config firewall policy6
  edit 1
    set auto-asic-offload disable
  end
```

For multicast security policies.

```
config firewall multicast-policy
  edit 1
    set auto-asic-offload disable
  end
```

Enabling strict protocol header checking disables all hardware acceleration

You can use the following command to cause the FortiGate to apply strict header checking to verify that a packet is part of a session that should be processed. Strict header checking includes verifying the layer-4 protocol header length, the IP header length, the IP version, the IP checksum, IP options, and verifying that ESP packets have the correct sequence number, SPI, and data length. If the packet fails header checking it is dropped by the FortiGate unit.

```
config system global
  check-protocol-header strict
end
```

Enabling strict header checking disables all hardware acceleration. This includes NP, SP, and CP processing.

sFlow and NetFlow and hardware acceleration

NP6 offloading is supported when you configure NetFlow for interfaces connected to NP6 processors.

Configuring sFlow on any interface disables all NP4 and NP6 offloading for all traffic on that interface. As well, configuring NetFlow on any interface disables NP4 offloading for all traffic on that interface.

Checking that traffic is offloaded by NP processors

A number of diagnose commands can be used to verify that traffic is being offloaded.

Using the packet sniffer

Use the packet sniffer to verify that traffic is offloaded. Offloaded traffic is not picked up by the packet sniffer so if you are sending traffic through the FortiGate unit and it is not showing up on the packet sniffer you can conclude

that it is offloaded.

```
diag sniffer packet port1 <option>
```

If you want the packet sniffer to be able to see offloaded traffic you can temporarily disable offloading the traffic, run the packet sniffer to view it and then re-enable offloading. As an example, you may want to sniff the traffic that is accepted by a specific firewall policy. You can edit the policy and set the `auto-asic-offload` option to `disable` to disable offloading this traffic. You can also disable offloading for IPsec VPN traffic, see [Disabling NP acceleration for individual IPsec VPN phase 1s on page 1249](#).

Checking the firewall session offload tag

Use the `diagnose sys session list` command to display sessions. If the output for a session includes the `npu info` field you should see information about session being offloaded. If the output doesn't contain an `npu info` field then the session has not been offloaded.

```
diagnose sys session list
session info: proto=6 proto_state=01 duration=34 expire=3565 timeout=3600
              flags=00000000 sockflag=00000000 sockport=0 av_idx=0 use=3

```

Verifying IPsec VPN traffic offloading

The following commands can be used to verify IPsec VPN traffic offloading to NP processors.

```
diagnose vpn ipsec status
NP1/NP2/NP4_0/sp_0_0:
  null: 0 0
  des: 0 0
    3des: 4075 4074
  aes: 0 0
  aria: 0 0
  seed: 0 0
  null: 0 0
    md5: 4075 4074
  sha1: 0 0
  sha256: 0 0
  sha384: 0 0
  sha512: 0 0
```

```

Dedicated management CPU

The web-based manager and CLI of FortiGate units with NP6 and NP4 processors may become unresponsive when the system is under heavy processing load because NP6 or NP4 interrupts overload the CPUs preventing CPU cycles from being used for management tasks. You can resolve this issue by using the following command to dedicate CPU core 0 to management tasks.

```

config system npu
  set dedicated-management-cpu {enable | disable}
end

```

All management tasks are then processed by CPU 0 and NP6 or NP4 interrupts are handled by the remaining CPU cores.

Offloading flow-based content inspection with NTurbo and IPSA

You can use the following command to configure NTurbo and IPA Advanced (IPSA) offloading and acceleration of firewall sessions that have flow-based security profiles. This includes firewall sessions with IPS, application control, CASI, flow-based antivirus and flow-based web filtering.

```
config ips global
  set np-accel-mode {none | basic}
  set cp-accel-mode {none | basic | advanced}
end
```

NTurbo offloads firewall sessions with flow-based security profiles to NPx processors

NTurbo offloads firewall sessions that include flow-based security profiles to NP4 or NP6 network processors. Without NTurbo, or with NTurbo disabled, all firewall sessions that include flow-based security profiles are processed by the FortiGate CPU.

NTurbo can only offload firewall sessions containing flow-based security profiles if the session could otherwise have been offloaded except for the presence of the flow-based security profiles. If something else prevents the session from being offloaded, NTurbo will not offload that session.

Firewall sessions that include proxy-based security profiles are never offloaded to network processors and are always processed by the FortiGate CPU.

NTurbo creates a special data path to redirect traffic from the ingress interface to IPS, and from IPS to the egress interface. NTurbo allows firewall operations to be offloaded along this path, and still allows IPS to behave as a stage in the processing pipeline, reducing the workload on the FortiGate CPU and improving overall throughput.

NTurbo sessions still offload pattern matching and other processes to CP processors, just like normal flow-based sessions.

If NTurbo is supported by your FortiGate unit, you can use the following command to configure it:

```
config ips global
  set np-accel-mode {basic | none}
end
```

`basic` enables NTurbo and is the default setting for FortiGate models that support NTurbo. `none` disables NTurbo. If the `np-accel-mode` option is not available, then your FortiGate does not support NTurbo.

There are some special cases where sessions may not be offloaded by NTurbo, even when NTurbo is explicitly enabled. In these cases the sessions are handled by the FortiGate CPU.

- NP acceleration is disabled. For example, `auto-asic-offload` is disabled in the firewall policy configuration.
- The firewall policy includes proxy-based security profiles.
- The sessions require FortiOS session-helpers. For example, FTP sessions can not be offloaded to NP processors because FTP sessions use the FTP session helper.

- Interface policies or DoS policies have been added to the ingress or egress interface.
- Tunneling is enabled. Any traffic to or from a tunneled interface (IPSec, IPinIP, SSL VPN, GRE, CAPWAP, etc.) cannot be offloaded by NTurbo.

IPSA offloads flow-based advanced pattern matching to CPx processors

IPSA offloads advanced or enhanced pattern matching operations required for flow-based content processing to CP8 and CP9 Content Processors. IPSA offloads enhanced pattern matching for NTurbo firewall sessions and firewall sessions that are not offloaded to NP processors. When IPSA is turned on, flow-based pattern databases are compiled and downloaded to the content processors from the IPS engine and IPS database. Flow-based pattern matching requests are redirected to the CP hardware reducing the load on the FortiGate CPU and accelerating pattern matching.

IF IPSA is supported on your FortiGate unit, you can use the following command to configure it:

```
config ips global
    set cp-accel-mode {advanced | basic | none}
end
```

`basic` offloads basic pattern matching. `advanced` offloads more types of pattern matching resulting in higher throughput than basic mode. `advanced` is only available on FortiGate models with two or more CP8s or one or more CP9s. If the `cp-accel-mode` option is not available, then your FortiGate does not support IPSA.

On FortiGates with one CP8, the default `cp-accel-mode` is `basic`. Setting the mode to `advanced` does not change the types of pattern matching that are offloaded.

On FortiGates with two or more CP8s or one or more CP9s the default `cp-accel-mode` is `advanced`. You can set the mode to `basic` to offload fewer types of pattern matching.

Preventing packet ordering problems with NP4, NP6 and NP6lite FortiGates under heavy load

In some cases when FortiGate units with NP4, NP6, or NP6lite processors are under heavy load the packets used in the TCP 3-way handshake of some sessions may be transmitted by the FortiGate in the wrong order resulting in the TCP sessions failing.

If you notice TCP sessions failing when a FortiGate with NP4, NP6, or NP6lite processors is very busy you can enable `delay-tcp-npu-session` in the firewall policy receiving the traffic. This option resolves the problem by delaying the session to make sure that there is time for all of the handshake packets to reach the destination before the session begins transmitting data.

```
config firewall policy
    set delay-tcp-npu-session enable
end
```

NP6 and NP6lite acceleration

NP6 and NP6lite network processors provide fastpath acceleration by offloading communication sessions from the FortiGate CPU. When the first packet of a new session is received by an interface connected to an NP6 processor, just like any session connecting with any FortiGate interface, the session is forwarded to the FortiGate CPU where it is matched with a security policy. If the session is accepted by a security policy and if the session can be offloaded its session key is copied to the NP6 processor that received the packet. All of the rest of the packets in the session are intercepted by the NP6 processor and fast-pathed out of the FortiGate unit to their destination without ever passing through the FortiGate CPU. The result is enhanced network performance provided by the NP6 processor plus the network processing load is removed from the CPU. In addition the NP6 processor can handle some CPU intensive tasks, like IPsec VPN encryption/decryption.

NP6lite processors have the same architecture and function in the same way as NP6 processors. All of the descriptions of NP6 processors in this document can be applied to NP6lite processors except where noted.

Session keys (and IPsec SA keys) are stored in the memory of the NP6 processor that is connected to the interface that received the packet that started the session. All sessions are fast-pathed and accelerated, even if they exit the FortiGate unit through an interface connected to another NP6. There is no dependence on getting the right pair of interfaces since the offloading is done by the receiving NP6.

The key to making this possible is an Integrated Switch Fabric (ISF) that connects the NP6s and the FortiGate unit interfaces together. Many FortiGate units with NP6 processors also have an ISF. The ISF allows any port connectivity. All ports and NP6s can communicate with each other over the ISF. There are no special ingress and egress fast path requirements as long as traffic enters and exits on interfaces connected to the same ISF.

Some FortiGate units, such as the FortiGate-1000D include multiple NP6 processors that are not connected by an ISF. Because the ISF is not present fast path acceleration is supported only between interfaces connected to the same NP6 processor. Since the ISF introduces some latency, models with no ISF provide low-latency network acceleration between network interfaces connected to the same NP6 processor.

Each NP6 has a maximum throughput of 40 Gbps using 4 x 10 Gbps XAUI or Quad Serial Gigabit Media Independent Interface (QSGMII) interfaces or 3 x 10 Gbps and 16 x 1 Gbps XAUI or QSGMII interfaces.

There are at least two limitations to keep in mind:

- The capacity of each NP6 processor. An individual NP6 processor can support between 10 and 16 million sessions. This number is limited by the amount of memory the processor has. Once an NP6 processor hits its session limit, sessions that are over the limit are sent to the CPU. You can avoid this problem by as much as possible distributing incoming sessions evenly among the NP6 processors. To be able to do this you need to be aware of which interfaces connect to which NP6 processors and distribute incoming traffic accordingly.

- The NP6 processors in some FortiGate units employ NP direct technology that removes the ISF. The result is very low latency but no inter-processor connectivity requiring you to make sure that traffic to be offloaded enters and exits the FortiGate through interfaces connected to the same NP processor.

NP6 session fast path requirements

NP6 processors can offload the following traffic and services:

- IPv4 and IPv6 traffic and NAT64 and NAT46 traffic (as well as IPv4 and IPv6 versions of the following traffic types where appropriate).
- Link aggregation (LAG) (IEEE 802.3ad) traffic (see [Increasing NP6 offloading capacity using link aggregation groups \(LAGs\) on page 1261](#)).
- TCP, UDP, ICMP, SCTP, and RDP traffic.
- IPsec VPN traffic, and offloading of IPsec encryption/decryption (including SHA2-256 and SHA2-512)
- IPsec traffic that passes through a FortiGate without being unencrypted.
- Anomaly-based intrusion prevention, checksum offload and packet defragmentation.
- IPIP tunneling (also called IP in IP tunneling), SIT tunneling, and IPv6 tunneling sessions.
- Multicast traffic (including Multicast over IPsec).
- CAPWAP and wireless bridge traffic tunnel encapsulation to enable line rate wireless forwarding from FortiAP devices (not supported by the NP6lite).
- Traffic shaping and priority queuing for both shared and per IP traffic shaping.
- Syn proxying (not supported by the NP6lite).
- DNS session helper (not supported by the NP6lite)/
- Inter-VDOM link traffic.

Sessions that are offloaded must be fast path ready. For a session to be fast path ready it must meet the following criteria:

- Layer 2 type/length must be 0x0800 for IPv4 or 0x86dd for IPv6 (IEEE 802.1q VLAN specification is supported).
- Layer 3 protocol can be IPv4 or IPv6.
- Layer 4 protocol can be UDP, TCP, ICMP, or SCTP.
- In most cases, Layer 3 / Layer 4 header or content modification sessions that require a session helper can be offloaded.
- Local host traffic (originated by the FortiGate unit) can be offloaded.
- If the FortiGate supports, NTurbo sessions can be offloaded if they are accepted by firewall policies that include IPS, Application Control, CASI, flow-based antivirus, or flow-based web filtering.

Offloading Application layer content modification is not supported. This means that sessions are not offloaded if they are accepted by firewall policies that include proxy-based virus scanning, proxy-based web filtering, DNS filtering, DLP, Anti-Spam, VoIP, ICAP, Web Application Firewall, or Proxy options.

If you disable anomaly checks by Intrusion Prevention (IPS), you can still enable hardware accelerated anomaly checks using the `fp-anomaly` field of the `config system interface` CLI command. See [Configuring individual NP6 processors on page 1265](#).

If a session is not fast path ready, the FortiGate unit will not send the session key or IPsec SA key to the NP6 processor. Without the session key, all session key lookup by a network processor for incoming packets of that

session fails, causing all session packets to be sent to the FortiGate unit's main processing resources, and processed at normal speeds.

If a session is fast path ready, the FortiGate unit will send the session key or IPsec SA key to the network processor. Session key or IPsec SA key lookups then succeed for subsequent packets from the known session or IPsec SA.

Packet fast path requirements

Packets within the session must then also meet packet requirements.

- Incoming packets must not be fragmented.
- Outgoing packets must not require fragmentation to a size less than 385 bytes. Because of this requirement, the configured MTU (Maximum Transmission Unit) for a network processor's network interfaces must also meet or exceed the network processors' supported minimum MTU of 385 bytes.

Mixing fast path and non-fast path traffic

If packet requirements are not met, an individual packet will be processed by the FortiGate CPU regardless of whether other packets in the session are offloaded to the NP6.

Also, in some cases, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing. For example, VoIP control packets may not be offloaded but VoIP data packets (voice packets) may be offloaded.

NP6Lite processors

The NP6Lite works the same way as the NP6. Being a lighter version, the NP6Lite has a lower capacity than the NP6. The NP6lite max throughput is 10 Gbps using 2x QSGMII and 2x Reduced gigabit media-independent interface (RGMII) interfaces.

Also, the NP6lite does not offload the following types of sessions:

- CAPWAP
- Syn proxy
- DNS session helper

NP6 and NP6Lite processors and sFlow and NetFlow

NP6 and NP6Lite offloading is supported when you configure NetFlow for interfaces connected to NP6 or NP6Lite processors. Offloading of other sessions is not affected by configuring NetFlow.

Configuring sFlow on any interface disables all NP6 and NP6Lite offloading for all traffic on that interface.

NP6 processors and traffic shaping

NP6-offloaded sessions support most types of traffic shaping. However, in bandwidth and out bandwidth traffic shaping, set using the following command, is not supported:

```
config system interface
  edit port1
    set outbandwidth <value>
    set inbandwidth <value>
  end
```

Configuring in bandwidth traffic shaping has no effect. Configuring out bandwidth traffic shaping imposes more limiting than configured, potentially reducing throughput more than expected.

NP Direct

On FortiGates with more than one NP6 processor, removing the Internal Switch Fabric (ISF) for NP Direct architecture provides direct access to the NP6 processors for the lowest latency forwarding. Because the NP6 processors are not connected, care must be taken with network design to make sure that all traffic to be offloaded enters and exits the FortiGate through interfaces connected to the same NP6 processor. As well Link Aggregation (LAG) interfaces should only include interfaces all connected to the same NP6 processor.

Example NP direct hardware with more than one NP6 processor includes:

- Ports 25 to 32 of the FortiGate-3700D in low latency mode.
- FortiGate-2000E
- FortiGate-2500E

Viewing your FortiGate NP6 processor configuration

Use either of the following commands to view the NP6 processor hardware configuration of your FortiGate unit:

```
get hardware npu np6 port-list
diagnose npu np6 port-list
```

If your FortiGate has NP6lite processors, you can use either of the following commands:

```
get hardware npu np6lite port-list
diagnose npu np6lite port-list
```

For example, for the FortiGate-5001D the output would be:

```
get hardware npu np6 port-list
```

Chip	XAUI	Ports	Max Speed	Cross-chip offloading
np6_0	0	port3	10G	Yes
	1			
	2	base1	1G	Yes
	3			
	0-3	port1	40G	Yes
	0-3	fabric1	40G	Yes
	0-3	fabric3	40G	Yes
	0-3	fabric5	40G	Yes
np6_1	0			
	1	port4	10G	Yes
	2			
	3	base2	1G	Yes
	0-3	port2	40G	Yes
	0-3	fabric2	40G	Yes
	0-3	fabric4	40G	Yes

For more example output for different FortiGate models, see [FortiGate NP6 architectures on page 1276](#) and [FortiGate NP6lite architectures on page 1326](#).

You can also use the following command to view the offloading features enabled or disabled on each of the NP6 processors in your FortiGate unit:

```
diagnose npu npu-feature
```

	np_0	np_1
Fastpath	Enabled	Enabled
Low-latency-mode	Disabled	Disabled
Low-latency-cap	No	No
IPv4 firewall	Yes	Yes
IPv6 firewall	Yes	Yes
IPv4 IPSec	Yes	Yes
IPv6 IPSec	Yes	Yes
IPv4 tunnel	Yes	Yes
IPv6 tunnel	Yes	Yes
GRE tunnel	No	No
IPv4 Multicast	Yes	Yes
IPv6 Multicast	Yes	Yes
CAPWAP	Yes	Yes

Disabling NP6 and NP6lite hardware acceleration (fastpath)

You can use the following command to disable NP6 offloading for all traffic. This option disables NP6 offloading for all traffic for all NP6 and NP6lite processors.

```
config system npu
    set fastpath disable
end
```

Optimizing NP6 performance by distributing traffic to XAUI links

On most FortiGate units with NP6 processors, the FortiGate interfaces are switch ports that connect to the NP6 processors with XAUI links. Packets pass from the interfaces to the NP6 processor over the XAUI links. Each NP6 processor has a 40 Gigabit bandwidth capacity. The four XAUI links each have a 10 Gigabit capacity for a total of 40 Gigabits.

On many FortiGate units with NP6 processors, the NP6 processors and the XAUI links are over-subscribed. Since the NP6 processors are connected by an Integrated Switch Fabric, you do not have control over how traffic is distributed to them. In fact traffic is distributed evenly by the ISF.

However, you can control how traffic is distributed to the XAUI links and you can optimize performance by distributing traffic evenly among the XAUI links. For example, if you have a very high amount of traffic passing between two networks, you can connect each network to interfaces connected to different XAUI links to distribute the traffic for each network to a different XAUI link.

For example, on a FortiGate-3200D (See [FortiGate-3200D fast path architecture on page 1300](#)), there are 48 10-Gigabit interfaces that send and receive traffic for two NP6 processors over a total of eight 10-Gigabit XAUI links. Each XAUI link gets traffic from six 10-Gigabit FortiGate interfaces. The amount of traffic that the FortiGate-3200D can offload is limited by the number of NP6 processors and the number of XAUI links. You can optimize the amount of traffic that the FortiGate-3200D can process by distributing it evenly among the XAUI links and the NP6 processors.

You can see the Ethernet interface, XAUI link, and NP6 configuration by entering the `get hardware npu np6 port-list` command. For the FortiGate-3200D the output is:

```

get hardware npu np6 port-list
Chip    XAUI Ports    Max    Cross-chip
        ----- Speed offloading
np6_0   0    port1    10G    Yes
        0    port5    10G    Yes
        0    port10   10G    Yes
        0    port13   10G    Yes
        0    port17   10G    Yes
        0    port22   10G    Yes
        1    port2    10G    Yes
        1    port6    10G    Yes
        1    port9    10G    Yes
        1    port14   10G    Yes
        1    port18   10G    Yes
        1    port21   10G    Yes
        2    port3    10G    Yes
        2    port7    10G    Yes
        2    port12   10G    Yes
        2    port15   10G    Yes
        2    port19   10G    Yes
        2    port24   10G    Yes
        3    port4    10G    Yes
        3    port8    10G    Yes
        3    port11   10G    Yes
        3    port16   10G    Yes
        3    port20   10G    Yes
        3    port23   10G    Yes
np6_1   0    port26   10G    Yes
        0    port29   10G    Yes
        0    port33   10G    Yes
        0    port37   10G    Yes
        0    port41   10G    Yes
        0    port45   10G    Yes
        1    port25   10G    Yes
        1    port30   10G    Yes
        1    port34   10G    Yes
        1    port38   10G    Yes
        1    port42   10G    Yes
        1    port46   10G    Yes
        2    port28   10G    Yes
        2    port31   10G    Yes
        2    port35   10G    Yes
        2    port39   10G    Yes
        2    port43   10G    Yes
        2    port47   10G    Yes
        3    port27   10G    Yes
        3    port32   10G    Yes
        3    port36   10G    Yes
        3    port40   10G    Yes
        3    port44   10G    Yes

```

```

      3      port48  10G      Yes
-----

```

In this command output you can see that each NP6 has for four XAUI links (0 to 3) and that each XAUI link is connected to six 10-gigabit Ethernet interfaces. To optimize throughput you should keep the amount of traffic being processed by each XAUI port to under 10 Gbps. So for example, if you want to offload traffic from four 10-gigabit networks you can connect these networks to Ethernet interfaces 1, 2, 3 and 4. This distributes the traffic from each 10-Gigabit network to a different XAUI link. Also, if you wanted to offload traffic from four more 10-Gigabit networks you could connect them to Ethernet ports 26, 25, 28, and 27. As a result each 10-Gigabit network would be connected to a different XAUI link.

Enabling bandwidth control between the ISF and NP6 XAUI ports

In some cases, the Internal Switch Fabric (ISF) buffer size may be larger than the buffer size of an NP6 XAUI port that receives traffic from the ISF. If this happens, burst traffic from the ISF may exceed the capacity of an XAUI port and sessions may be dropped.

You can use the following command to configure bandwidth control between the ISF and XAUI ports. Enabling bandwidth control can smooth burst traffic and keep the XAUI ports from getting overwhelmed and dropping sessions.

Use the following command to enable bandwidth control:

```

config system npu
    set sw-np-bandwidth {0G | 2G | 4G | 5G | 6G}
end

```

The default setting is 0G which means no bandwidth control. The other options limit the bandwidth to 2Gbps, 4Gbps and so on.

Increasing NP6 offloading capacity using link aggregation groups (LAGs)

NP6 processors can offload sessions received by interfaces in link aggregation groups (LAGs) (IEEE 802.3ad). A 802.3ad Link Aggregation and its management protocol, Link Aggregation Control Protocol (LACP) LAG combines more than one physical interface into a group that functions like a single interface with a higher capacity than a single physical interface. For example, you could use a LAG if you want to offload sessions on a 30 Gbps link by adding three 10-Gbps interfaces to the same LAG.

All offloaded traffic types are supported by LAGs, including IPsec VPN traffic. Just like with normal interfaces, traffic accepted by a LAG is offloaded by the NP6 processor connected to the interfaces in the LAG that receive the traffic to be offloaded. If all interfaces in a LAG are connected to the same NP6 processor, traffic received by that LAG is offloaded by that NP6 processor. The amount of traffic that can be offloaded is limited by the capacity of the NP6 processor.

If a FortiGate has two or more NP6 processors connected by an integrated switch fabric (ISF), you can use LAGs to increase offloading by sharing the traffic load across multiple NP6 processors. You do this by adding physical interfaces connected to different NP6 processors to the same LAG.

Adding a second NP6 processor to a LAG effectively doubles the offloading capacity of the LAG. Adding a third further increases offloading. The actual increase in offloading capacity may not actually be doubled by adding a second NP6 or tripled by adding a third. Traffic and load conditions and other factors may limit the actual offloading result.

The increase in offloading capacity offered by LAGs and multiple NP6s is supported by the integrated switch fabric (ISF) that allows multiple NP6 processors to share session information. Most FortiGate units with multiple NP6 processors also have an ISF. However, the FortiGate-1000D does not have an ISF. On this model and others that have more than one NP6 and no ISF, if you attempt to add interfaces connected to different NP6 processors to a LAG the system displays an error message.

There are also a few limitations to LAG NP6 offloading support for IPsec VPN:

- IPsec VPN anti-replay protection cannot be used if IPsec is configured on a LAG that has interfaces connected to multiple NP6 processors.
- Because the encrypted traffic for one IPsec VPN tunnel has the same 5-tuple, the traffic from one tunnel can only be balanced to one interface in a LAG. This limits the maximum throughput for one IPsec VPN tunnel in an NP6 LAG group to 10Gbps.

Configuring inter-VDOM link acceleration with NP6 processors

FortiGate units with NP6 processors include inter-VDOM links that can be used to accelerate inter-VDOM link traffic.

- For a FortiGate unit with two NP6 processors there are two accelerated inter-VDOM links, each with two interfaces:
 - **npu0_vlink:**
npu0_vlink0
npu0_vlink1
 - **npu1_vlink:**
npu1_vlink0
npu1_vlink1

These interfaces are visible from the GUI and CLI. For a FortiGate unit with NP6 interfaces, enter the following CLI command to display the NP6-accelerated inter-VDOM links:

```
get system interface
...
== [ npu0_vlink0 ]
name: npu0_vlink0 mode: static ip: 0.0.0.0 0.0.0.0 status: down netbios-forward: disable
type: physical sflow-sampler: disable explicit-web-proxy: disable explicit-ftp-proxy:
disable mtu-override: disable wccp: disable drop-overlapped-fragment: disable drop-
fragment: disable

== [ npu0_vlink1 ]
name: npu0_vlink1 mode: static ip: 0.0.0.0 0.0.0.0 status: down netbios-forward: disable
type: physical sflow-sampler: disable explicit-web-proxy: disable explicit-ftp-proxy:
disable mtu-override: disable wccp: disable drop-overlapped-fragment: disable drop-
fragment: disable

== [ npu1_vlink0 ]
name: npu1_vlink0 mode: static ip: 0.0.0.0 0.0.0.0 status: down netbios-forward: disable
type: physical sflow-sampler: disable explicit-web-proxy: disable explicit-ftp-proxy:
disable mtu-override: disable wccp: disable drop-overlapped-fragment: disable drop-
fragment: disable

== [ npu1_vlink1 ]
name: npu1_vlink1 mode: static ip: 0.0.0.0 0.0.0.0 status: down netbios-forward: disable
type: physical sflow-sampler: disable explicit-web-proxy: disable explicit-ftp-proxy:
disable mtu-override: disable wccp: disable drop-overlapped-fragment: disable drop-
fragment: disable
...
```

By default the interfaces in each inter-VDOM link are assigned to the root VDOM. To use these interfaces to accelerate inter-VDOM link traffic, assign each interface in the pair to the VDOMs that you want to offload traffic between. For example, if you have added a VDOM named New-VDOM to a FortiGate unit with NP4 processors, you can go to **System > Network > Interfaces** and edit the **npu0-vlink1** interface and set the **Virtual Domain** to **New-VDOM**. This results in an accelerated inter-VDOM link between root and New-VDOM. You can also do this from the CLI:

```
config system interface
  edit npu0-vlink1
    set vdom New-VDOM
  end
```

Using VLANs to add more accelerated inter-VDOM links

You can add VLAN interfaces to the accelerated inter-VDOM links to create inter-VDOM links between more VDOMs. For the links to work, the VLAN interfaces must be added to the same inter-VDOM link, must be on the same subnet, and must have the same VLAN ID.

For example, to accelerate inter-VDOM link traffic between VDOMs named Marketing and Engineering using VLANs with VLAN ID 100 go to **System > Network > Interfaces** and select **Create New** to create the VLAN interface associated with the Marketing VDOM:

Name	Marketing-link
Type	VLAN
Interface	npu0_vlink0
VLAN ID	100
Virtual Domain	Marketing
IP/Network Mask	172.20.120.12/24

Create the inter-VDOM link associated with Engineering VDOM:

Name	Engineering-link
Type	VLAN
Interface	npu0_vlink1
VLAN ID	100
Virtual Domain	Engineering
IP/Network Mask	172.20.120.22/24

Or do the same from the CLI:

```
config system interface
  edit Marketing-link
    set vdom Marketing
```

```

set ip 172.20.120.12/24
set interface npu0_vlink0
set vlanid 100
next
edit Engineering-link
set vdom Engineering
set ip 172.20.120.22/24
set interface npu0_vlink1
set vlanid 100

```

Confirm that the traffic is accelerated

Use the following CLI commands to obtain the interface index and then correlate them with the session entries. In the following example traffic was flowing between new accelerated inter-VDOM links and physical ports port1 and port 2 also attached to the NP6 processor.

diagnose ip address list

```

IP=172.31.17.76->172.31.17.76/255.255.252.0 index=5 devname=port1
IP=10.74.1.76->10.74.1.76/255.255.252.0 index=6 devname=port2
IP=172.20.120.12->172.20.120.12/255.255.255.0 index=55 devname=IVL-VLAN1_ROOT
IP=172.20.120.22->172.20.120.22/255.255.255.0 index=56 devname=IVL-VLAN1_VDOM1

```

Disabling offloading IPsec Diffie-Hellman key exchange

You can use the following command to disable using ASIC offloading to accelerate IPsec Diffie-Hellman key exchange for IPsec ESP traffic. By default hardware offloading is used. For debugging purposes or other reasons you may want this function to be processed by software.

Use the following command to disable using ASIC offloading for IPsec Diffie-Hellman key exchange:

```

config system global
    set ipsec-asic-offload disable
end

```

Configuring individual NP6 processors

You can use the `config system np6` command to configure a wide range of settings for each of the NP6 processors in your FortiGate unit including enabling session accounting and adjusting session timeouts. As well you can set anomaly checking for IPv4 and IPv6 traffic.

You can also enable and adjust Host Protection Engine (HPE) to protect networks from DoS attacks by categorizing incoming packets based on packet rate and processing cost and applying packet shaping to packets that can cause DoS attacks.

The settings that you configure for an NP6 processor with the `config system np6` command apply to traffic processed by all interfaces connected to that NP6 processor. This includes the physical interfaces connected to the NP6 processor as well as all subinterfaces, VLAN interfaces, IPsec interfaces, LAGs and so on associated with the physical interfaces connected to the NP6 processor.

Some of the options for this command apply anomaly checking for NP6 sessions in the same way as the command described in [Offloading NP4 anomaly detection on page 1336](#) applies anomaly checking for NP4 sessions.

```

config system np6
    edit <np6-processor-name>
        set low-latency-mode {disable | enable}
        set per-session-accounting {all-enable | disable | enable-by-log}
        set session-timeout-random-range <range>
        set garbage-session-collector {disable | enable}
        set session-collector-interval <range>
        set session-timeout-interval <range>
        set session-timeout-random-range <range>
        set session-timeout-fixed {disable | enable}
        config hpe
            set tcpsyn-max <packets-per-second>
            set tcp-max <packets-per-second>
            set udp-max <packets-per-second>
            set icmp-max <packets-per-second>

end

```

Command syntax

Command	Description	Default
low-latency-mode {disable enable}	Enable low-latency mode. In low latency mode the integrated switch fabric is bypassed. Low latency mode requires that packet enter and exit using the same NP6 processor. This option is only available for NP6 processors that can operate in low-latency mode, currently only np6_0 and np6_1 on the FortiGate-3700D and DX.	disable

Command	Description	Default
<code>per-session-accounting</code> {all-enable disable enable-by-log}	Disable NP6 per-session accounting or enable it and control how it works. If set to <code>enable-by-log</code> (the default) NP6 per-session accounting is only enabled if firewall policies accepting offloaded traffic have traffic logging enabled. If set to <code>all-enable</code> , NP6 per-session accounting is always enabled for all traffic offloaded by the NP6 processor. Enabling per-session accounting can affect performance.	enable-by-log
<code>garbage-session-collector</code> {disable enable}	Enable deleting expired or garbage sessions.	disable
<code>session-collector-interval</code> <range>	Set the expired or garbage session collector time interval in seconds. The range is 1 to 100 seconds.	64
<code>session-timeout-interval</code> <range>	Set the timeout for checking for and removing inactive NP6 sessions. The range is 0 to 1000 seconds.	40
<code>session-timeout-random-range</code> <range>	Set the random timeout for checking and removing inactive NP6 sessions. The range is 0 to 1000 seconds.	8
<code>session-timeout-fixed</code> {disable enable}	Enable to force checking for and removing inactive NP6 sessions at the <code>session-timeout-interval</code> time interval. Set to <code>disable</code> (the default) to check for and remove inactive NP6 sessions at random time intervals.	disable
config hpe		
<code>hpe</code>	Use the following options to use HPE to apply DDoS protection at the NP6 processor by limiting the number packets per second received for various packet types by each NP6 processor. This rate limiting is applied very efficiently because it is done in hardware by the NP6 processor.	
<code>enable-shaper</code> {disable enable}	Enable or disable HPE DDoS protection.	disable
<code>tcpsyn-max</code>	Limit the maximum number of TCP SYN packets received per second. The range is 10,000 to 4,000,000,000 pps. The default limits the number of packets per second to 5,000,000 pps.	5000000

Command	Description	Default
<code>tcp-max</code>	Limit the maximum number of TCP packets received per second. The range is 10,000 to 4,000,000,000 pps. The default limits the number of packets per second to 5,000,000 pps.	5000000
<code>udp-max</code>	Limit the maximum number of UDP packets received per second. The range is 10,000 to 4,000,000,000 pps. The default limits the number of packets per second to 5,000,000 pps.	5000000
<code>icmp-max</code>	Limit the maximum number of ICMP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
<code>sctp-max</code>	Limit the maximum number of SCTP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
<code>esp-max</code>	Limit the maximum number of ESP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
<code>ip-frag-max</code>	Limit the maximum number of fragmented IP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
<code>ip-others-max</code>	Limit the maximum number of other types of IP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
<code>arp-max</code>	Limit the maximum number of ARP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
<code>l2-others-max</code>	Limit the maximum number of other layer-2 packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
config fp-anomaly		
<code>fp-anomaly-v4</code>	Configure how the NP6 processor does traffic anomaly protection. In most cases you can configure the NP6 processor to allow or drop the packets associated with an attack or forward the packets that are associated with the attack to FortiOS (called <code>trap-to-host</code>). Selecting <code>trap-to-host</code> turns off NP6 anomaly protection for that anomaly. If you require anomaly protection but don't want to use the NP6 processor, you can select <code>trap-to-host</code> and enable anomaly protection with a DoS policy.	

Command	Description	Default
<code>tcp-syn-fin {allow drop trap-to-host}</code>	Detects TCP SYN flood SYN/FIN flag set anomalies.	allow
<code>tcp_fin_noack {allow drop trap-to-host}</code>	Detects TCP SYN flood with FIN flag set without ACK setting anomalies.	trap-to-host
<code>tcp_fin_only {allow drop trap-to-host}</code>	Detects TCP SYN flood with only FIN flag set anomalies.	trap-to-host
<code>tcp_no_flag {allow drop trap-to-host}</code>	Detects TCP SYN flood with no flag set anomalies.	allow
<code>tcp_syn_data {allow drop trap-to-host}</code>	Detects TCP SYN flood packets with data anomalies.	allow
<code>tcp-winnuke {allow drop trap-to-host}</code>	Detects TCP WinNuke anomalies.	trap-to-host
<code>tcp-land {allow drop trap-to-host}</code>	Detects TCP land anomalies.	trap-to-host
<code>udp-land {allow drop trap-to-host}</code>	Detects UDP land anomalies.	trap-to-host
<code>icmp-land {allow drop trap-to-host}</code>	Detects ICMP land anomalies.	trap-to-host
<code>icmp-frag {allow drop trap-to-host}</code>	Detects Layer 3 fragmented packets that could be part of a layer 4 ICMP anomalies.	allow
<code>ipv4-land {allow drop trap-to-host}</code>	Detects IPv4 land anomalies.	trap-to-host
<code>ipv4-proto-err {allow drop trap-to-host}</code>	Detects invalid layer 4 protocol anomalies.	trap-to-host
<code>ipv4-unknopt {allow drop trap-to-host}</code>	Detects unknown option anomalies.	trap-to-host
<code>ipv4-optrr {allow drop trap-to-host}</code>	Detects IPv4 with record route option anomalies.	trap-to-host
<code>ipv4-optssrr {allow drop trap-to-host}</code>	Detects IPv4 with strict source record route option anomalies.	trap-to-host
<code>ipv4-optlsrr {allow drop trap-to-host}</code>	Detects IPv4 with loose source record route option anomalies.	trap-to-host

Command	Description	Default
ipv4-optstream {allow drop trap-to-host}	Detects stream option anomalies.	trap-to-host
ipv4-optsecurity {allow drop trap-to-host}	Detects security option anomalies.	trap-to-host
ipv4-opttimestamp {allow drop trap-to-host}	Detects timestamp option anomalies.	trap-to-host
ipv4-csum-err {drop trap-to-host}	Detects IPv4 checksum errors.	drop
tcp-csum-err {drop trap-to-host}	Detects TCP checksum errors.	drop
udp-csum-err {drop trap-to-host}	Detects UDP checksum errors.	drop
icmp-csum-err {drop trap-to-host}	Detects ICMP checksum errors.	drop
ipv6-land {allow drop trap-to-host}	Detects IPv6 land anomalies	trap-to-host
ipv6-unknopt {allow drop trap-to-host}	Detects unknown option anomalies.	trap-to-host
ipv6-saddr-err {allow drop trap-to-host}	Detects source address as multicast anomalies.	trap-to-host
ipv6-daddr_err {allow drop trap-to-host}	Detects destination address as unspecified or loopback address anomalies.	trap-to-host
ipv6-optralert {allow drop trap-to-host}	Detects router alert option anomalies.	trap-to-host
ipv6-optjumbo {allow drop trap-to-host}	Detects jumbo options anomalies.	trap-to-host
ipv6-opttunnel {allow drop trap-to-host}	Detects tunnel encapsulation limit option anomalies.	trap-to-host
ipv6-opthomeaddr {allow drop trap-to-host}	Detects home address option anomalies.	trap-to-host
ipv6-optnsap {allow drop trap-to-host}	Detects network service access point address option anomalies.	trap-to-host

Command	Description	Default
<code>ipv6-optendpid {allow drop trap-to-host}</code>	Detects end point identification anomalies.	trap-to-host
<code>ipv6-optinvld {allow drop trap-to-host}</code>	Detects invalid option anomalies.	trap-to-host

Enabling per-session accounting for offloaded NP6 and NP6lite sessions

Per-session accounting is a logging feature that allows the FortiGate to report the correct bytes/pkt numbers per session for sessions offloaded to an NP6 or NP6lite processor. This information appears in traffic log messages as well as in FortiView. The following example shows the Sessions dashboard widget tracking SPU and nTurbo sessions.

You can hover over the SPU icon to see some information about the offloaded sessions.

You configure per-session accounting for each NP6 processor. For example, use the following command to enable per-session accounting for NP6_0 and NP6_1:

```
config system np6
  edit np6_0
    set per-session-accounting enable-by-log
  next
  edit np6_1
    set per-session-accounting enable-by-log
  end
```

If your FortiGate has NP6lite processors, you can use the following command to enable per-session accounting for all of the NP6lite processors in the FortiGate unit:

```
config system npu
  set per-session-accounting enable-by-log
end
```

The option, `enable-by-log` enables per-session accounting for offloaded sessions with traffic logging enabled and `all-enable` enables per-session accounting for all offloaded sessions.

By default, `per-session-accounting` is set to `enable-by-log`, which results in per-session accounting being turned on when you enable traffic logging in a policy.

Per-session accounting can affect offloading performance. So you should only enable per-session accounting if you need the accounting information.

Enabling per-session accounting does not provide traffic flow data for sFlow or NetFlow.

Configuring NP6 session timeouts

For NP6 traffic, FortiOS refreshes an NP6 session's lifetime when it receives a session update message from the NP6 processor. To avoid session update message congestion, these NP6 session checks are performed all at once after a random time interval and all of the update messages are sent from the NP6 processor to FortiOS at once. This can result in fewer messages being sent because they are only sent at random time intervals instead of every time a session times out.

In fact, if your NP6 processor is processing a lot of short lived sessions, it is recommended that you use the default setting of random checking every 8 seconds to avoid very bursty session updates. If the time between session updates is very long and very many sessions have been expired between updates a large number of updates will need to be done all at once.

You can use the following command to set the random time range.

```
config system np6
  edit <np6-processor-name>
    set session-timeout-fixed disable
    set session-timeout-random-range 8
  end
```

This is the default configuration. The random timeout range is 1 to 1000 seconds and the default range is 8. So, by default, NP6 sessions are checked at random time intervals of between 1 and 8 seconds. So sessions can be inactive for up to 8 seconds before they are removed from the FortiOS session table.

If you want to reduce the amount of checking you can increase the `session-timeout-random-range`. This could result in inactive sessions being kept in the session table longer. But if most of your NP6 sessions are relatively long this shouldn't be a problem.

You can also change this session checking to a fixed time interval and set a fixed timeout:

```
config system np6
  edit <np6-processor-name>
    set session-timeout-fixed enable
    set session-timeout-fixed 40
  end
```

The fixed timeout default is every 40 seconds and the range is 1 to 1000 seconds. Using a fixed interval further reduces the amount of checking that occurs.

You can select random or fixed updates and adjust the time intervals to minimize the refreshing that occurs while still making sure inactive sessions are deleted regularly. For example, if an NP6 processor is processing sessions with long lifetimes you can reduce checking by setting a relatively long fixed timeout.

Configure the number of IPsec engines NP6 processors use

NP6 processors use multiple IPsec engines to accelerate IPsec encryption and decryption. In some cases out of order ESP packets can cause problems if multiple IPsec engines are running. To resolve this problem you can configure all of the NP6 processors to use fewer IPsec engines.

Use the following command to change the number of IPsec engines used for decryption (`ipsec-dec-subengine-mask`) and encryption (`ipsec-enc-subengine-mask`). These settings are applied to all of the NP6 processors in the FortiGate unit.

```
config system npu
    set ipsec-dec-subengine-mask <engine-mask>
    set ipsec-enc-subengine-mask <engine-mask>
end
```

<engine-mask> is a hexadecimal number in the range 0x01 to 0xff where each bit represents one IPsec engine. The default <engine-mask> for both options is 0xff which means all IPsec engines are used. Add a lower <engine-mask> to use fewer engines. You can configure different engine masks for encryption and decryption.

Stripping clear text padding and IPsec session ESP padding

In some situations, when clear text or ESP packets in IPsec sessions may have large amounts of layer 2 padding, the NP6 IPsec engine may not be able to process them and the session may be blocked.

If you notice dropped IPsec sessions, you could try using the following CLI options to cause the NP6 processor to strip clear text padding and ESP padding before send the packets to the IPsec engine. With padding stripped, the session can be processed normally by the IPsec engine.

Use the following command to strip ESP padding:

```
config system npu
    set strip-esp-padding enable
    set strip-clear-text-padding enable
end
```

Stripping clear text and ESP padding are both disabled by default.

Disable NP6 CAPWAP offloading

By default and where possible, managed FortiAP and FortiLink CAPWAP sessions are offloaded to NP6 processors. You can use the following command to disable CAPWAP session offloading:

```
config system npu
    set capwap-offload disable
end
```

Optionally disable NP6 offloading of traffic passing between 10Gbps and 1Gbps interfaces

Due to NP6 internal packet buffer limitations, some offloaded packets received at a 10Gbps interface and destined for a 1Gbps interface can be dropped, reducing performance for TCP and IP tunnel traffic. If you experience this performance reduction, you can use the following command to disable offloading sessions passing from 10Gbps interfaces to 1Gbps interfaces:

```
config system npu
    set host-shortcut-mode host-shortcut
end
```

Select `host-shortcut` to stop offloading TCP and IP tunnel packets passing from 10Gbps interfaces to 1Gbps interfaces. TCP and IP tunnel packets passing from 1Gbps interfaces to 10Gbps interfaces are still offloaded as normal.

If `host-shortcut` is set to the default `bi-directional` setting, packets in both directions are offloaded.

This option is only available if your FortiGate has 10G and 1G interfaces accelerated by NP6 processors.

Offloading RDP traffic

FortiOS supports NP6 offloading of Reliable Data Protocol (RDP) traffic. RDP is a network transport protocol that optimizes remote loading, debugging, and bulk transfer of images and data. RDP traffic uses Assigned Internet Protocol number 27 and is defined in [RFC 908](#) and updated in [RFC 1151](#). If your network is processing a lot of RDP traffic, offloading it can improve overall network performance.

You can use the following command to enable or disable NP6 RDP offloading. RDP offloading is enabled by default.

```
config system npu
    set rdp-offload {disable | enable}
end
```

NP6 session drift

In some cases, sessions processed by NP6 processors may fail to be deleted leading to a large number of idle sessions. This is called session drift. You can use SNMP to be alerted when the number of idle sessions becomes high. SNMP also allows you to see which NP6 processor has the abnormal number of idle sessions and you can use a diagnose command to delete them.

The following MIB fields allow you to use SNMP to monitor session table information for NP6 processors including drift for each NP6 processor:

```
FORTINET-FORTIGATE-MIB::fgNPUNumber.0 = INTEGER: 2
FORTINET-FORTIGATE-MIB::fgNPUName.0 = STRING: NP6
FORTINET-FORTIGATE-MIB::fgNPUDrvDriftSum.0 = INTEGER: 0
FORTINET-FORTIGATE-MIB::fgNPUIndex.0 = INTEGER: 0
FORTINET-FORTIGATE-MIB::fgNPUIndex.1 = INTEGER: 1
FORTINET-FORTIGATE-MIB::fgNPUSessionTblSize.0 = Gauge32: 33554432
FORTINET-FORTIGATE-MIB::fgNPUSessionTblSize.1 = Gauge32: 33554432
FORTINET-FORTIGATE-MIB::fgNPUSessionCount.0 = Gauge32: 0
FORTINET-FORTIGATE-MIB::fgNPUSessionCount.1 = Gauge32: 0
FORTINET-FORTIGATE-MIB::fgNPUDrvDrift.0 = INTEGER: 0
FORTINET-FORTIGATE-MIB::fgNPUDrvDrift.1 = INTEGER: 0
```

You can also use the following diagnose command to determine if drift is occurring:

```
diagnose npu np6 sse-drift-summary
NPU    drv-drift
-----
np6_0  0
np6_1  0
-----
Sum    0
-----
```

The command output shows a drift summary for all the NP6 processors in the system, and shows the total drift. Normally the sum is 0. The previous command output, from a FortiGate-1500D, shows that the 1500D's two NP6 processors are not experiencing any drift.

If the sum is not zero, then extra idle sessions may be accumulating. You can use the following command to delete those sessions:

```
diagnose npu np6 sse-purge-drift <np6_id> [<time>]
```

Where `<np6_id>` is the number (starting with NP6_0 with a `np6_id` of 0) of the NP6 processor for which to delete idle sessions in. `<time>` is the age in seconds of the idle sessions to be deleted. All idle sessions this age and older are deleted. The default time is 300 seconds.

The `diagnose npu np6 sse-stats <np6_id>` command output also includes a `drv-drift` field that shows the total drift for one NP6 processor.

Optimizing FortiGate-3960E and 3980E IPsec VPN performance

You can use the following command to configure outbound hashing to improve IPsec VPN performance for the FortiGate-3960E and 3980E. If you change these settings, to make sure they take affect, you should reboot your device.

```
config system np6
  edit np6_0
    set ipsec-outbound-hash {disable | enable}
    set ipsec-ob-hash-function {switch-group-hash | global- hash | global-hash-weighted
                              | round-robin-switch-group | round-robin-global}
  end
```

Where:

`ipsec-outbound-hash` is disabled by default. If you enable it you can set `ipsec-ob-hash-function` as follows:

`switch-group-hash` (the default) distribute outbound IPsec Security Association (SA) traffic to NP6 processors connected to the same switch as the interfaces that received the incoming traffic. This option, keeps all traffic on one switch and the NP6 processors connected to that switch, to improve performance.

`global-hash` distribute outbound IPsec SA traffic among all NP6 processors.

`global-hash-weighted` distribute outbound IPsec SA traffic from switch 1 among all NP6 processors with more sessions going to the NP6s connected to switch 0. This options is only recommended for the FortiGate-3980E because it is designed to weigh switch 0 hider to send more sessions to switch 0 which on the FortiGate-3980E has more NP6 processors connected to it. On the FortiGate-3960E both switches have the same number of NP6s so for best performance one switch shouldn't have a higher weight.

`round-robin-switch-group` round-robin distribution of outbound IPsec SA traffic among the NP6 processors connected to the same switch.

`round-robin-global` round-robin distribution of outbound IPsec SA traffic among all NP6 processors.

Recalculating packet checksums if the `iph.reserved` bit is set to 0

NP6 and the NP6lite processors clear the `iph.flags.reserved` bit. This results in the packet checksum becoming incorrect because by default the packet is changed but the checksum is not recalculated. Since the checksum is incorrect these packets may be dropped by the network stack. You can enable this option to cause the system to re-calculate the checksum. Enabling this option may cause a minor performance reduction. This option is disabled by default.

To enabled checksum recalculation for packets with the `iph.flags.reserved` header:

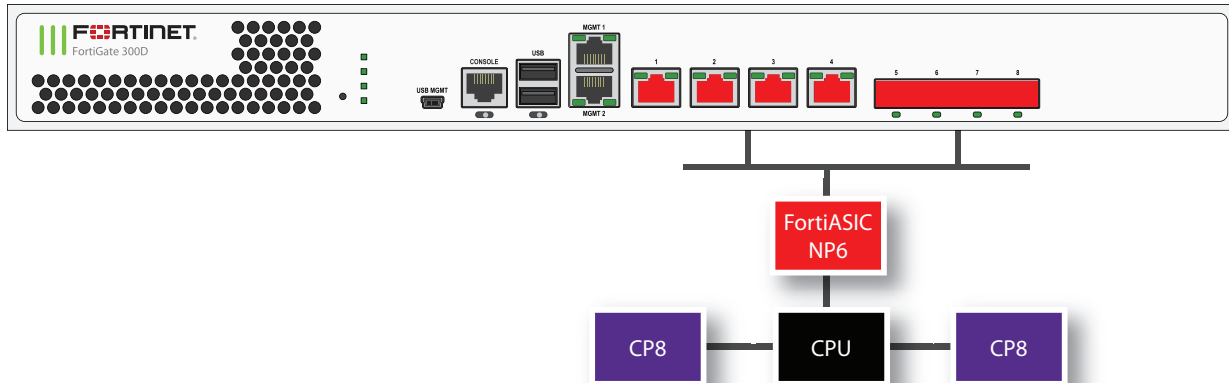

```
config system npu
  set iph-rsvd-re-cksum enable
end
```

FortiGate NP6 architectures

This chapter shows the NP6 architecture for the all FortiGate models that include NP6 processors.

FortiGate-300D fast path architecture

The FortiGate-300D includes one NP6 processor connected to four 1Gb RJ-45 Ethernet ports (port1-4) and four 1Gb SFP interfaces (port5-port8).

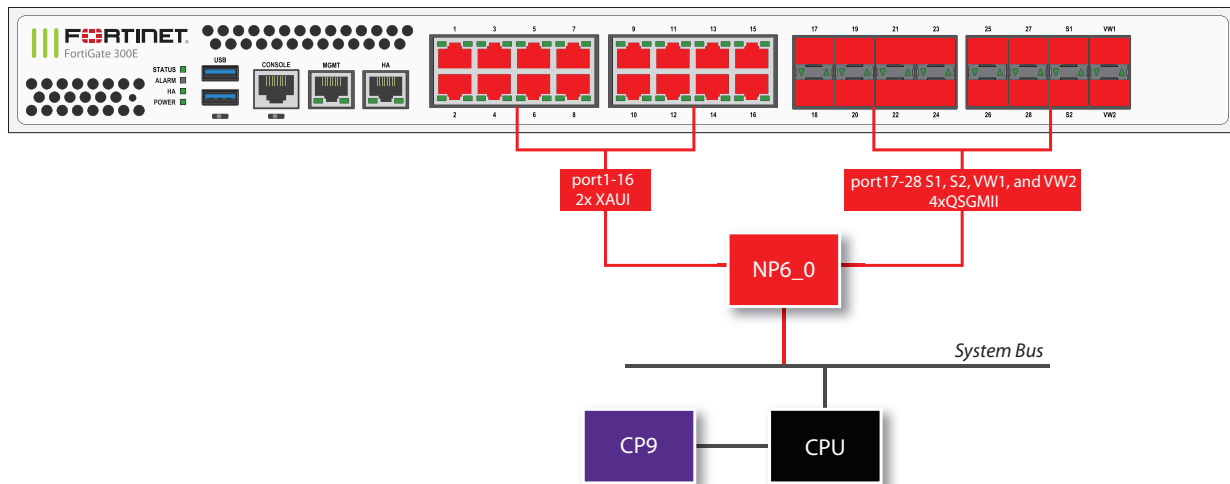

You can use the following get command to display the FortiGate-300D NP6 configuration. The command output shows one NP6 named NP6_0 and the interfaces (ports) connected to it. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
Chip  XAUI Ports  Max  Cross-chip
      Speed offloading
-----
np6_0  0
      1  port5   1G   Yes
      1  port7   1G   Yes
      1  port8   1G   Yes
      1  port6   1G   Yes
      1  port3   1G   Yes
      1  port4   1G   Yes
      1  port1   1G   Yes
      1  port2   1G   Yes
      2
      3
-----
```

FortiGate-300E and 301E fast path architecture

The FortiGate-300E and 301E each include one NP6 processor. All front panel data interfaces (port1 to 28, S1, S2, VW1, and VW2) connect to the NP6 processor. So all supported traffic passing between any two data interfaces can be offloaded.

The following diagram also shows the XAUI and QSGMII port connections between the NP6 processor and the front panel interfaces.

You can use the following `get` command to display the FortiGate-300E or 301E NP6 configuration. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

Chip	XAUI	Ports	Max Speed	Cross-chip offloading
np6_0	0	port1	1G	Yes
	0	port2	1G	Yes
	0	port3	1G	Yes
	0	port4	1G	Yes
	0	port5	1G	Yes
	0	port6	1G	Yes

	3	port28	1G	Yes
	3	s1	1G	Yes
	3	s2	1G	Yes

3	vw1	1G	Yes
3	vw2	1G	Yes

FortiGate-400D fast path architecture

The FortiGate-400D includes one NP6 processor connected to eight 1Gb SFP interfaces (port1-port8) and eight 1Gb RJ-45 Ethernet ports (port9-16).

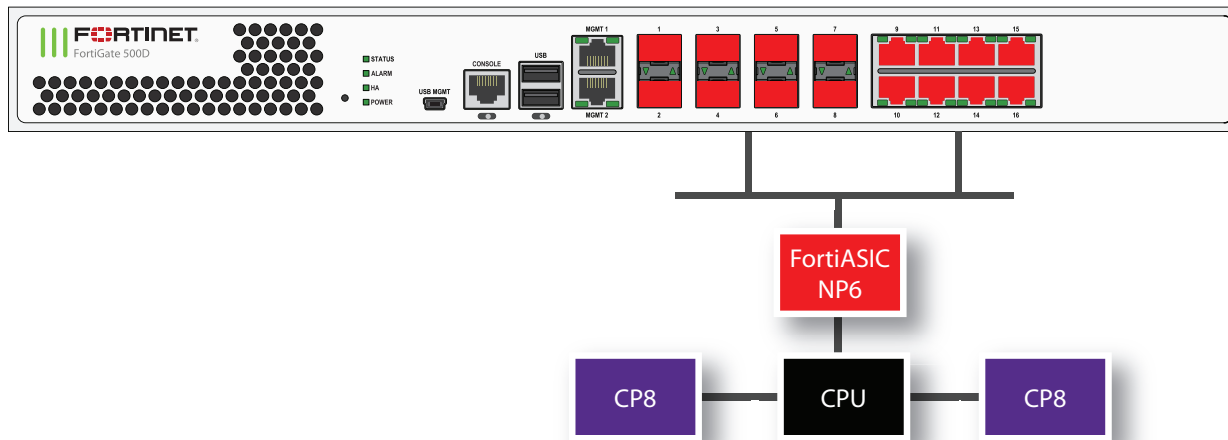

You can use the following get command to display the FortiGate-400D NP6 configuration. The command output shows one NP6 named NP6_0 and the interfaces (ports) connected to it. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list

-----
```

FortiGate-800D fast path architecture

The FortiGate-800D includes one NP6 processor connected through an integrated switch fabric to all of the FortiGate-800D network interfaces. This hardware configuration supports NP6-accelerated fast path offloading for sessions between any of the FortiGate-800D interfaces.

You can use the following `get` command to display the FortiGate-800D NP6 configuration. The command output shows one NP6 named NP6_0. The output also shows all of the FortiGate-800D interfaces (ports) connected to NP6_0. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

	3	port32	10G	Yes

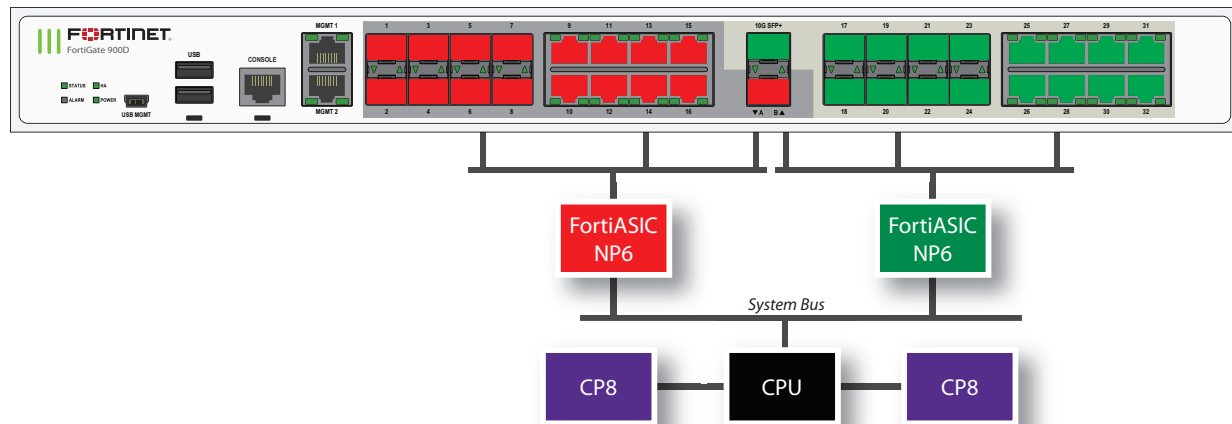

FortiGate-900D fast path architecture

The FortiGate-900D includes two NP6 processors that are not connected by an integrated switch fabric (ISF). Without an ISF, traffic through a FortiGate-900D could experience lower latency than traffic through similar hardware with an ISF. The NP6 processors are connected to network interfaces as follows:

Because the FortiGate-900D does not have an ISF you cannot create Link Aggregation Groups (LAGs) that include interfaces connected to both NP6 processors.

- Eight 1Gb SFP interfaces (port17-port24), eight 1Gb RJ-45 Ethernet interfaces (port25-32) and one 10Gb SFP+ interface (portB) share connections to the first NP6 processor.
- Eight 1Gb SFP interfaces (port1-port8), eight RJ-45 Ethernet interfaces (port9-16) and one 10Gb SFP+ interface (portA) share connections to the second NP6 processor.

You can use the following get command to display the FortiGate-900D NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```

FortiGate-1200D fast path architecture

The FortiGate-1200D features two NP6 processors both connected to an integrated switch fabric.

- Eight SFP 1Gb interfaces (port1-port8), eight RJ-45 Ethernet ports (port17-24) and two SFP+ 10Gb interfaces (port33 and port34) share connections to the first NP6 processor.
- Eight SFP 1Gb interfaces (port9-port16), eight RJ-45 Ethernet ports (port25-32) and two SFP+ 10Gb interfaces (port35-port36) share connections to the second NP6 processor.

You can use the following `get` command to display the FortiGate-1200D NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```

get hardware npu np6 port-list

FortiGate-1500DT fast path architecture

The FortiGate-1500DT features two NP6 processors both connected to an integrated switch fabric. The FortiGate-1500DT has the same hardware configuration as the FortiGate-1500D, but with the addition of newer CPUs.

The FortiGate-1500DT includes the following interfaces and NP6 processors:

- Eight SFP 1Gb interfaces (port1-port8), eight RJ-45 1Gb Ethernet interfaces (port17-24) and four RJ-45 10Gb Ethernet interfaces (port33-port36) share connections to the first NP6 processor.
- Eight SFP 1Gb interfaces (port9-port16), eight RJ-45 1Gb Ethernet interfaces (port25-32) and four SFP+ 10Gb interfaces (port37-port40) share connections to the second NP6 processor.

You can use the following get command to display the FortiGate-1500DT NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

FortiGate-2000E fast path architecture

The FortiGate-2000E includes three NP6 processors in an NP Direct configuration. The NP6 processors connected to the 10GigE ports are also in a low latency NP Direct configuration. Because of NP Direct, you cannot create Link Aggregation Groups (LAGs) between interfaces connected to different NP6s. As well, traffic will only be offloaded if it enters and exits the FortiGate on interfaces connected to the same NP6.

The NP6s are connected to network interfaces as follows:

- NP6_0 is connected to four 10GigE SFP+ interfaces (port33 to port36) in a low latency configuration.
- NP6_1 is connected to thirty-two 10/100/1000BASE-T interfaces (port1 to port32).
- NP6_2 is connected to two 10GigE SFP+ (port37 and port38) in a low latency configuration.

The following diagram also shows the XAUI and QSGMII port connections between the NP6 processors and the front panel interfaces and the aggregate switch for the thirty-two 10/100/1000BASE-T interfaces.

You can use the following get command to display the FortiGate-2000E NP6 configuration. You can also use the `diagnose npu np6 port-list` command to display this information.

```

get hardware npu np6 port-list
Chip      XAUI  Ports      Max      Cross-chip
          XAUI  Ports      Speed    offloading

FortiGate-2500E fast path architecture

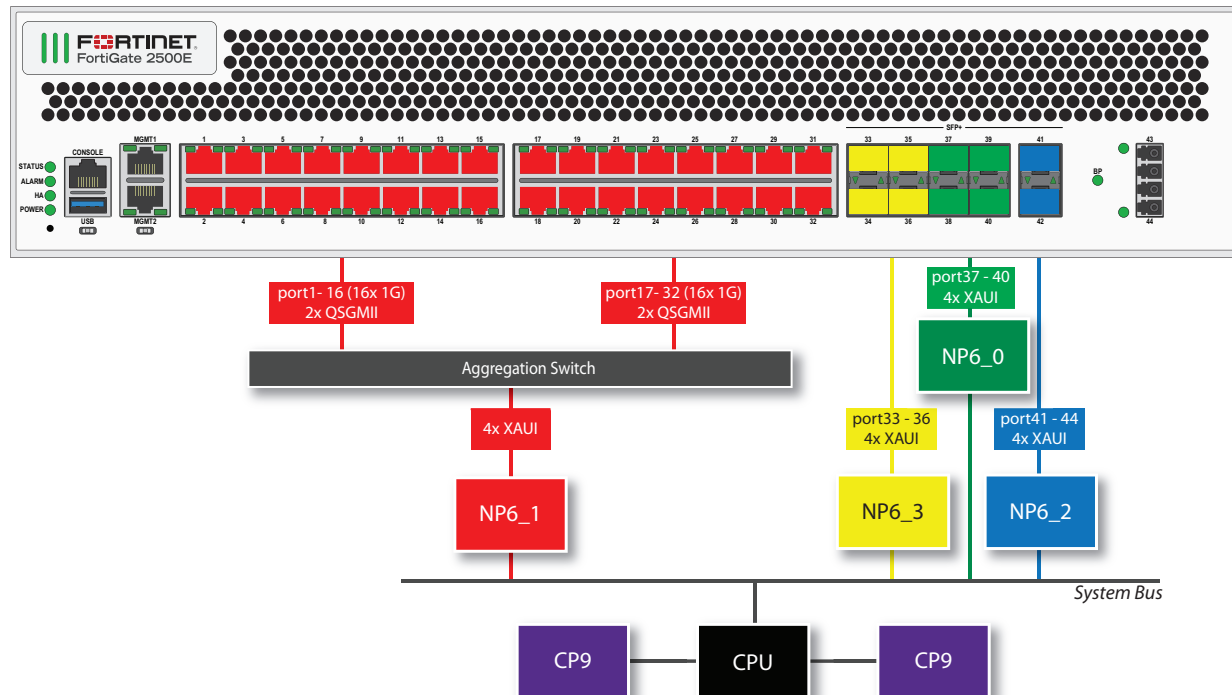

The FortiGate-2500E includes four NP6 processors in an NP Direct configuration. The NP6 processors connected to the 10GigE ports are also in a low latency NP Direct configuration. Because of NP Direct, you cannot create

Link Aggregation Groups (LAGs) between interfaces connected to different NP6s. As well, traffic will only be offloaded if it enters and exits the FortiGate on interfaces connected to the same NP6.

The NP6s are connected to network interfaces as follows:

- NP6_0 is connected to four 10GigE SFP+ interfaces (port37 to port40) in a low latency configuration.
- NP6_1 is connected to thirty-two 10/100/1000BASE-T interfaces (port1 to port32).
- NP6_2 is connected to two 10GigE SFP+ interfaces (port41 and port42) and two 10 Gig fiber bypass interfaces (port43 and port44) in a low latency configuration.
- NP6_3 is connected to four 10GigE SFP+ interfaces (port33 to port36) in a low latency configuration.

The following diagram also shows the XAUI and QSGMII port connections between the NP6 processors and the front panel interfaces and the aggregate switch for the thirty-two 10/100/1000BASE-T interfaces.

You can use the following get command to display the FortiGate-2500E NP6 configuration. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

FortiGate-3700D fast path architecture

The FortiGate-3700D features four NP6 processors. The first two NP6 processors (np6_0 and np6_1) can be configured for low latency operation. The low latency configuration changes the FortiGate-3700D fast path architecture.

FortiGate-3700D low latency fast path architecture

Ports 25 to 32 can be used for low latency offloading. As long as traffic enters and exits the FortiGate-3700D through ports connected to the same NP6 processor and using these low latency ports the traffic will be offloaded and have lower latency than other NP6 offloaded traffic. Latency is reduced by bypassing the integrated switch fabric (ISF).

You can use the following command to turn on low latency mode for np6_0 and np6_1:

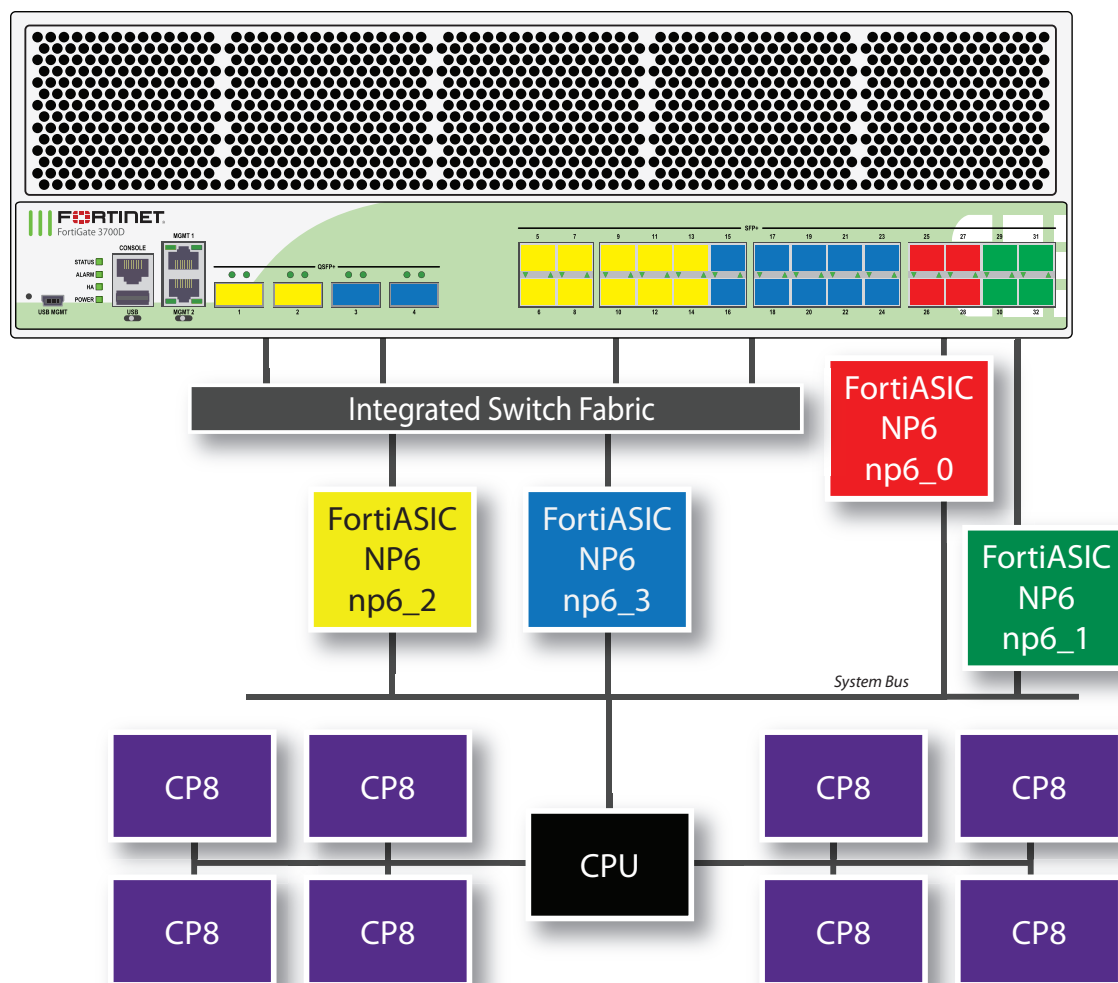

```
config system np6
  edit np6_0
    set low-latency-mode enable
  next
  edit np6_1
    set low-latency-mode enable
end
```

You do not have to turn on low latency to both np6_0 and np6_1. If you turn on low latency for just one NP6, the other NP6 will still be mapped according to the normal latency configuration.

With low latency enabled for both np6_0 and np6_1 the FortiGate-3700D has the following fastpath architecture:

- Four SFP+ 10Gb interfaces, port25 to port28, share connections to the first NP6 processor (np6_0) so sessions entering one of these ports and exiting through another will experience low latency
- Four SFP+ 10Gb interfaces, port29 to port32, share connections to the second NP6 processor (np6_1) so sessions entering one of these ports and exiting through another will experience low latency
- Ten SFP+ 10Gb interfaces, port5 to port14, and two 40Gb QSFP interfaces, port1 and port2, share connections to the third NP6 processor (np6_2).
- Ten SFP+ 10Gb interfaces, port15 to port24, and two 40Gb QSFP interfaces, port3 and port4, share connections to the fourth NP6 processor (np6_3).

You can use the following get command to display the FortiGate-3700D NP6 configuration. In this output example, the first two NP6s (np6_0 and np6_1) are configured for low latency. The command output shows four NP6s named NP6_0, NP6_1, NP6_2, and NP6_3 and the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

Chip	XAUI Ports	Max Speed	Cross-chip offloading
np6_2	0 port5	10G	Yes
	0 port9	10G	Yes
	0 port13	10G	Yes
	1 port6	10G	Yes
	1 port10	10G	Yes
	1 port14	10G	Yes
	2 port7	10G	Yes
	2 port11	10G	Yes
	3 port8	10G	Yes
	3 port12	10G	Yes
	0-3 port1	40G	Yes

	0-3	port2	40G	Yes

np6_3	0	port15	10G	Yes
	0	port19	10G	Yes
	0	port23	10G	Yes
	1	port16	10G	Yes
	1	port20	10G	Yes
	1	port24	10G	Yes
	2	port17	10G	Yes
	2	port21	10G	Yes
	3	port18	10G	Yes
	3	port22	10G	Yes
	0-3	port3	40G	Yes
	0-3	port4	40G	Yes

np6_0	0	port26	10G	No
	1	port25	10G	No
	2	port28	10G	No
	3	port27	10G	No

np6_1	0	port30	10G	No
	1	port29	10G	No
	2	port32	10G	No
	3	port31	10G	No

FortiGate-3700D normal latency fast path architecture

You can use the following command to turn off low latency mode for np6_0 and np6_1:

```
config system np6
  edit np6_0
    set low-latency-mode disable
  next
  edit np6_1
    set low-latency-mode disable
end
```

You do not have to turn off low latency to both np6_0 and np6_1. If you turn off low latency to just one NP6, the other NP6 will still be mapped according to the normal configuration.

In addition to turning off low latency, entering these commands also changes how ports are mapped to NP6s. Port1 is now mapped to np6_0 and port 3 is not mapped to np6_1. The FortiGate-3700D has the following fastpath architecture:

- One 40Gb QSFP interface, port1, and four SFP+ 10Gb interfaces, port25 to port28 share connections to the first NP6 processor (np6_0).
- One 40Gb QSFP interface, port3, and four SFP+ 10Gb interfaces, port29 to port32 share connections to the second NP6 processor (np6_1).
- One 40Gb QSFP interface, port2 and ten SFP+ 10Gb interfaces, port5 to port14 share connections to the third NP6 processor (np6_2).

- One 40Gb QSFP interface, port4, and ten SFP+ 10Gb interfaces, port15 to port24 share connections to the fourth NP6 processor (np6_3).

You can use the following get command to display the FortiGate-3700D NP6 configuration with low latency turned off for np6_0 and np6_1. The command output shows four NP6s named NP6_0, NP6_1, NP6_2, and NP6_3 and the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

Chip	XAUI	Ports	Max Speed	Cross-chip offloading

FortiGate-3700DX fast path architecture

The FortiGate-3700DX features four NP6 processors. The first two NP6 processors (np6_0 and np6_1) can be configured for low latency operation. The low latency configuration changes the FortiGate-3700D fast path architecture. The FortiGate-3700DX also includes two TP2 cards that offload GTPu sessions.

FortiGate-3700DX low latency fast path architecture

Ports 25 to 32 can be used for low latency offloading. As long as traffic enters and exits the FortiGate-3700D through ports connected to the same NP6 processor and using these low latency ports the traffic will be offloaded and have lower latency than other NP6 offloaded traffic. Latency is reduced by bypassing the integrated switch fabric (ISF).

You can use the following command to turn on low latency mode for np6_0 and np6_1:

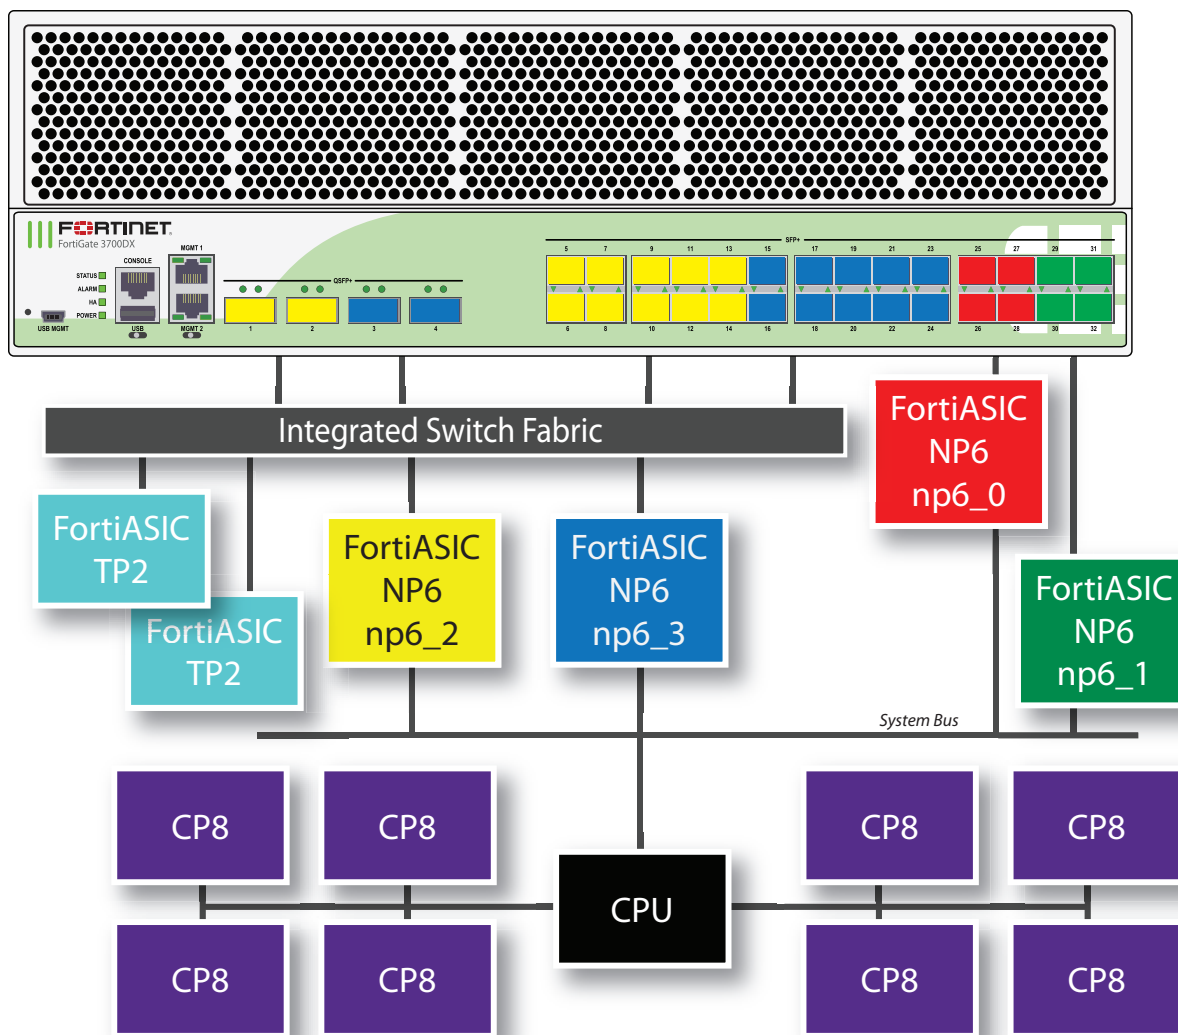

```
config system np6
  edit np6_0
    set low-latency-mode enable
  next
  edit np6_1
    set low-latency-mode enable
end
```

You do not have to turn on low latency to both np6_0 and np6_1. If you turn on low latency for just one NP6, the other NP6 will still be mapped according to the normal latency configuration.

With low latency enabled for both np6_0 and np6_1 the FortiGate-3700D has the following fastpath architecture:

- Four SFP+ 10Gb interfaces, port25 to port28, share connections to the first NP6 processor (np6_0) so sessions entering one of these ports and exiting through another will experience low latency
- Four SFP+ 10Gb interfaces, port29 to port32, share connections to the second NP6 processor (np6_1) so sessions entering one of these ports and exiting through another will experience low latency
- Ten SFP+ 10Gb interfaces, port5 to port14, and two 40Gb QSFP interfaces, port1 and port2, share connections to the third NP6 processor (np6_2).
- Ten SFP+ 10Gb interfaces, port15 to port24, and two 40Gb QSFP interfaces, port3 and port4, share connections to the fourth NP6 processor (np6_3).

You can use the following get command to display the FortiGate-3700D NP6 configuration. In this output example, the first two NP6s (np6_0 and np6_1) are configured for low latency. The command output shows four

NP6s named NP6_0, NP6_1, NP6_2, and NP6_3 and the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

Chip	XAUI	Ports	Max Speed	Cross-chip offloading

np6_2	0	port5	10G	Yes
	0	port9	10G	Yes
	0	port13	10G	Yes
	1	port6	10G	Yes
	1	port10	10G	Yes
	1	port14	10G	Yes
	2	port7	10G	Yes
	2	port11	10G	Yes
	3	port8	10G	Yes
	3	port12	10G	Yes
	0-3	port1	40G	Yes
	0-3	port2	40G	Yes

np6_3	0	port15	10G	Yes
	0	port19	10G	Yes
	0	port23	10G	Yes
	1	port16	10G	Yes
	1	port20	10G	Yes
	1	port24	10G	Yes
	2	port17	10G	Yes
	2	port21	10G	Yes
	3	port18	10G	Yes
	3	port22	10G	Yes
	0-3	port3	40G	Yes
	0-3	port4	40G	Yes

np6_0	0	port26	10G	No
	1	port25	10G	No
	2	port28	10G	No
	3	port27	10G	No

np6_1	0	port30	10G	No
	1	port29	10G	No
	2	port32	10G	No
	3	port31	10G	No

FortiGate-3700D normal latency fast path architecture

You can use the following command to turn off low latency mode for np6_0 and np6_1:

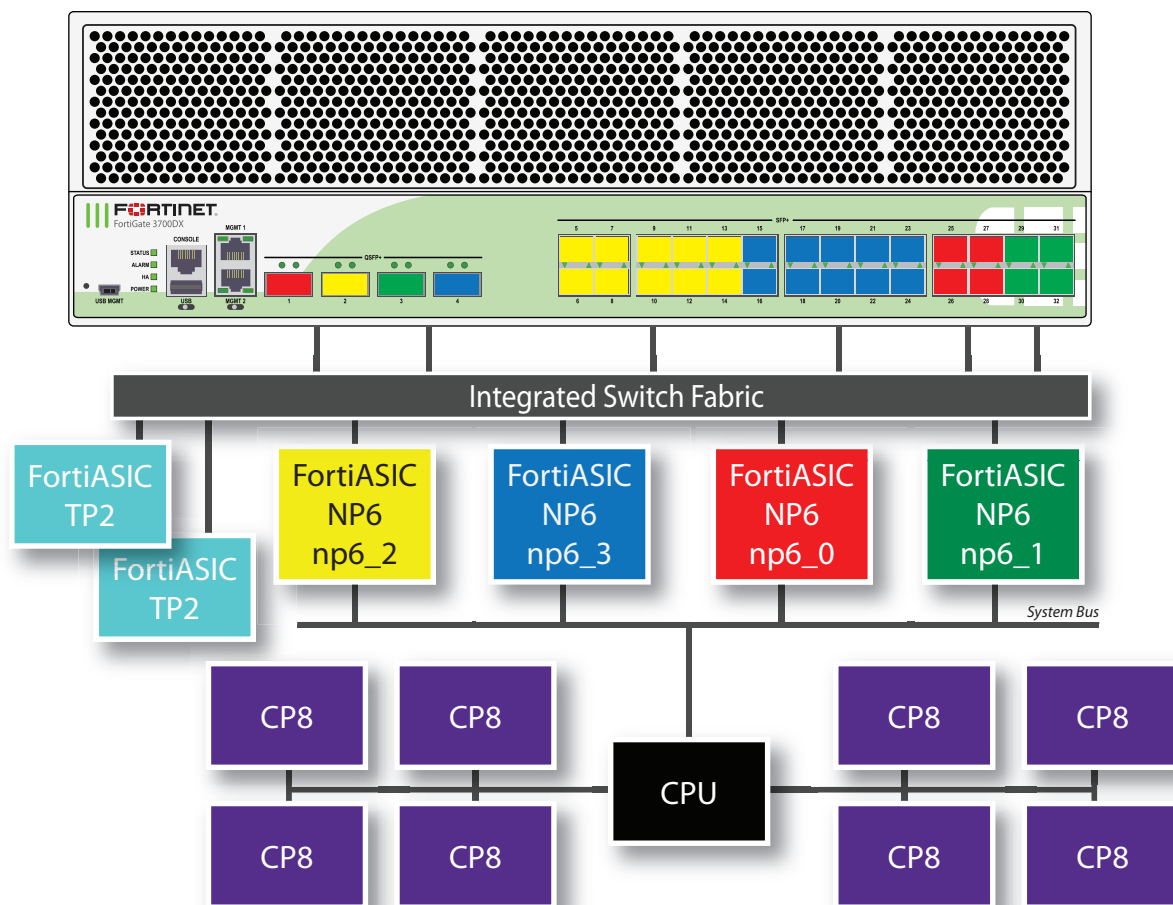

```
config system np6
  edit np6_0
    set low-latency-mode disable
  next
  edit np6_1
    set low-latency-mode disable
end
```

You do not have to turn off low latency to both np6_0 and np6_1. If you turn off low latency to just one NP6, the other NP6 will still be mapped according to the normal configuration.

In addition to turning off low latency, entering these commands also changes how ports are mapped to NP6s. Port1 is now mapped to np6_0 and port 3 is not mapped to np6_1. The FortiGate-3700D has the following fastpath architecture:

- One 40Gb QSFP interface, port1, and four SFP+ 10Gb interfaces, port25 to port28 share connections to the first NP6 processor (np6_0).
- One 40Gb QSFP interface, port3, and four SFP+ 10Gb interfaces, port29 to port32 share connections to the second NP6 processor (np6_1).
- One 40Gb QSFP interface, port2 and ten SFP+ 10Gb interfaces, port5 to port14 share connections to the third NP6 processor (np6_2).
- One 40Gb QSFP interface, port4, and ten SFP+ 10Gb interfaces, port15 to port24 share connections to the fourth NP6 processor (np6_3).

You can use the following get command to display the FortiGate-3700D NP6 configuration with low latency turned off for np6_0 and np6_1. The command output shows four NP6s named NP6_0, NP6_1, NP6_2, and NP6_3 and the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

NP6 interface mapping with split ports

If you use the following CLI command to split port1:

```
config system global
    set split-port port1
end
```

The new split ports (port1/1 to port 1/4) are mapped to the same NP6 as the port1 interface:

```
diagnose npu np6 port-list
```

FortiGate-5001E and 5001E1 fast path architecture

The FortiGate-5001E and 5001E1 features two NP6 processors and an integrated switch fabric. The integrated switch fabric allows you to configure aggregate interfaces between interfaces connected to different NP6s and supports offloading between for traffic entering and exiting from any interfaces.

The NP6s are connected to network interfaces as follows:

- NP6_0 is connected to port1, port3, fabric1, and base1.
- NP6_1 is connected to port2, port4, fabric2, and base2.

The following diagram also shows the XAUI port connections between the NP6 processors and the front panel interfaces and the integrated switch fabric.

NP6 default interface mapping

You can use the following get command to display the FortiGate-5001E NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6.

You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

FortiController-5902D fast path architecture

The FortiController-5902D NP6 network processors and integrated switch fabric (ISF) provide hardware acceleration by offloading load balancing from the primary FortiController-5902D CPU. Network processors are especially useful for accelerating load balancing of TCP and UDP sessions.

The first packet of every new session is received by the primary FortiController-5902D and the primary FortiController-5902D uses its load balancing schedule to select the worker that will process the new session. This information is passed back to an NP6 network processor and all subsequent packets of the same sessions are offloaded to an NP6 network processor which sends the packet directly to a subordinate unit. Load balancing is effectively offloaded from the primary unit to the NP6 network processors resulting in a faster and more stable active-active cluster.

Traffic accepted by the FortiController-5902D F1 to F4 interfaces is that is processed by the primary FortiController-5902D is also be offloaded to the NP6 processors.

Individual FortiController-5902D interfaces are not mapped to NP6 processors. Instead an Aggregator connects the all fabric interfaces to the ISF and no special mapping is required for fastpath offloading.

NP6 content clustering mode interface mapping

FortiController-5902Ds run in content clustering mode and load balance sessions to FortiGate-5001D workers. Use the following command to enable content clustering:

```

config system elbc
    set mode content-cluster
    set inter-chassis-support enable
end

```

You can use the following get command to display the content clustering FortiController-5902D NP6 configuration. The output shows that all ports are mapped to all NP6 processors. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

FortiGate NP6lite architectures

This chapter shows the NP6lite architecture for the all FortiGate models that include NP6lite processors.

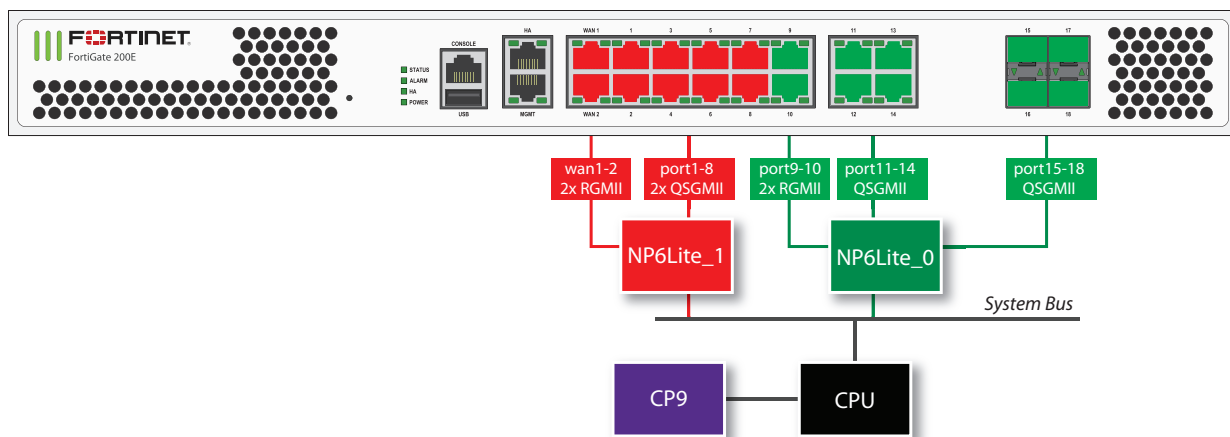

FortiGate-200E and 201E fast path architecture

The FortiGate-200E and 201E include two NP6lite processors. Because of this model does not include a switch fabric, you cannot create Link Aggregation Groups (LAGs) between interfaces connected to different NP6lites. As well traffic will only be offloaded if it enters and exits the FortiGate on interfaces connected to the same NP6lite.

The NP6lites are connected to network interfaces as follows:

- NP6lite_0 is connected to six 1GE RJ-45 interfaces (port9-port14) and four 1GE SFP interfaces (port15-18).
- NP6lite_1 is connected to ten 1GE RJ45 interfaces (wan1, wan2, port1-port8).

The following diagram also shows the RGMII and QSGMII port connections between the NP6lite processors and the front panel interfaces. Both RGMII and QSGMII interfaces operate at 1000Mbps. However, QSGMII interfaces can also negotiate to operate at lower speeds: 10, 100, and 1000Mbps. To connect the FortiGate-200E to networks with speeds lower than 1000Mbps use the QSGMII interfaces (port1-8 and port11-18).

You can use the following get command to display the FortiGate-200E or 201E NP6lite configuration. You can also use the `diagnose npu np6lite port-list` command to display this information.

```

get hardware npu np6lite port-list
Chip    XAUI Ports          Max    Cross-chip
        -----          Speed offloading

```

NP4 and NP4Lite acceleration

NP4 network processors provide fastpath acceleration by offloading communication sessions from the FortiGate CPU. When the first packet of a new session is received by an interface connected to an NP4 processor, just like any session connecting with any FortiGate interface, the session is forwarded to the FortiGate CPU where it is matched with a security policy. If the session is accepted by a security policy and if the session can be offloaded its session key is copied to the NP4 processor that received the packet. All of the rest of the packets in the session are intercepted by the NP4 processor and fast-pathed out of the FortiGate unit to their destination without ever passing through the FortiGate CPU. The result is enhanced network performance provided by the NP4 processor plus the network processing load is removed from the CPU. In addition, the NP4 processor can handle some CPU intensive tasks, like IPsec VPN encryption/decryption.

NP4lite processors have the same architecture and function in the same way as NP4 processors. All of the descriptions of NP4 processors in this document can be applied to NP4lite processors except where noted.

Session keys (and IPsec SA keys) are stored in the memory of the NP4 processor that is connected to the interface that received the packet that started the session. All sessions are fast-pathed and accelerated, even if they exit the FortiGate unit through an interface connected to another NP4. The key to making this possible is the Integrated Switch Fabric (ISF) that connects the NP4s and the FortiGate unit interfaces together. The ISF allows any port connectivity. All ports and NP4s can communicate with each other over the ISF.

There are no special ingress and egress fast path requirements because traffic enters and exits on interfaces connected to the same ISF. Most FortiGate models with multiple NP4 processors connect all interfaces and NP4 processors to the same ISF (except management interfaces) so this should not ever be a problem.

There is one limitation to keep in mind; the capacity of each NP4 processor. An individual NP4 processor has a capacity of 20 Gbps (10 Gbps ingress and 10 Gbps egress). Once an NP4 processor hits its limit, sessions that are over the limit are sent to the CPU. You can avoid this problem by as much as possible distributing incoming sessions evenly among the NP4 processors. To be able to do this you need to be aware of which interfaces connect to which NP4 processors and distribute incoming traffic accordingly.

Some FortiGate units contain one NP4 processor with all interfaces connected to it and to the ISF. As a result, offloading is supported for traffic between any pair of interfaces.

Some FortiGate units include NP4Lite processors. These network processors have the same functionality and limitations as NP4 processors but with about half the performance. NP4lite processors can be found in mid-range FortiGate models such as the FortiGate-200D and 240D.

Viewing your FortiGate NP4 processor configuration

To list the NP4 network processors on your FortiGate unit, use the following CLI command.

```
get hardware npu np4 list
```

The output lists the interfaces that have NP4 processors. For example, for a FortiGate-5001C:

```
get hardware npu np4 list
ID      Model      Slot      Interface
0       On-board
        port1 port2 port3 port4
        fabric1 base1 npu0-vlink0 npu0-vlink1
```

```
1      On-board                port5 port6 port7 port8
                                fabric2 base2 npu1-vlink0 npu1-vlink1
```

NP4lite CLI commands (disabling NP4Lite offloading)

If your FortiGate unit includes an NP4Lite processor the following commands will be available:

- Use the following command to disable or enable NP4Lite offloading. By default NP4lite offloading is enabled. If you want to disable NP4Lite offloading to diagnose a problem enter:

```
diagnose npu nplite fastpath disable
```

This command disables NP4Lite offloading until your FortiGate reboots. You can also re-enable offloading by entering the following command:

```
diagnose npu nplite fastpath enable
```

- NP4lite debug command. Use the following command to debug NP4Lite operation:

```
diagnose npl npl_debug {<parameters>}
```

NP4Lite option to disable offloading ICMP traffic in IPsec tunnels

In some cases ICMP traffic in IPsec VPN tunnels may be dropped by the NP4Lite processor due to a bug with the NP4Lite firmware. You can use the following command to avoid this problem by preventing the NP4Lite processor from offloading ICMP sessions in IPsec VPN tunnels. This command is only available on FortiGate models with NP4Lite processors, such as the FortiGate/FortiWiFi-60D.

```
config system npu
    set process-icmp-by-host {disable | enable}
end
```

The option is disabled by default and all ICMP traffic in IPsec VPN tunnels is offloaded where possible. If you are noticing that ICMP packets in IPsec VPN tunnels are being dropped you can disable this option and have all ICMP traffic processed by the CPU and not offloaded to the NP4Lite.

NP4 and NP4Lite processors and sFlow and NetFlow

Configuring sFlow or NetFlow on any interface disables all NP4 or NP4Lite offloading for all traffic on that interface.

Configuring NP4 traffic offloading

Offloading traffic to a network processor requires that the FortiGate unit configuration and the traffic itself is suited to hardware acceleration. There are requirements for path the sessions and the individual packets.

NP4 session fast path requirements

Sessions must be fast path ready. Fast path ready session characteristics are:

- Layer 2 type/length must be 0x0800 (IEEE 802.1q VLAN specification is supported)
- Layer 3 protocol must be IPv4
- Layer 4 protocol must be UDP, TCP or ICMP
- Layer 3 / Layer 4 header or content modification must not require a session helper (for example, SNAT, DNAT, and TTL reduction are supported, but application layer content modification is not supported)

- Firewall policies must not include proxy-based security features (proxy-based virus scanning, proxy-based web filtering, DNS filtering, DLP, Anti-Spam, VoIP, ICAP, Web Application Firewall, or Proxy options).
- If the FortiGate supports NTurbo, firewall policies can include flow-based security features (IPS, Application Control CASI, flow-based antivirus, or flow-based web filtering) .
- Origin must not be local host (the FortiGate unit)

If you disable anomaly checks by Intrusion Prevention (IPS), you can still enable NP4 hardware accelerated anomaly checks using the `fp-anomaly` field of the `config system interface` CLI command. See [Offloading NP4 anomaly detection on page 1336](#)

If a session is not fast path ready, the FortiGate unit will not send the session key to the network processor(s). Without the session key, all session key lookup by a network processor for incoming packets of that session fails, causing all session packets to be sent to the FortiGate unit's main processing resources, and processed at normal speeds.

If a session is fast path ready, the FortiGate unit will send the session key to the network processor(s). Session key lookup then succeeds for subsequent packets from the known session.

Packet fast path requirements

Packets within the session must then also meet packet requirements.

- Incoming packets must not be fragmented.
- Outgoing packets must not require fragmentation to a size less than 385 bytes. Because of this requirement, the configured MTU (Maximum Transmission Unit) for network processors' network interfaces must also meet or exceed the network processors' supported minimum MTU of 385 bytes.

If packet requirements are not met, an individual packet will use FortiGate unit main processing resources, regardless of whether other packets in the session are offloaded to the specialized network processor(s).

In some cases, due to these requirements, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing.

For example, FTP uses two connections: a control connection and a data connection. The control connection requires a session helper, and cannot be offloaded, but the data connection does not require a session helper, and can be offloaded. Within the offloadable data session, fragmented packets will not be offloaded, but other packets will be offloaded.

Some traffic types differ from general offloading requirements, but still utilize some of the network processors' encryption and other capabilities. Exceptions include IPsec traffic and active-active high availability (HA) load balanced traffic.

Mixing fast path and non-fast path traffic

If packet requirements are not met, an individual packet will be processed by the FortiGate CPU regardless of whether other packets in the session are offloaded to the NP4.

Also, in some cases, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing. For example, VoIP control packets may not be offloaded but VoIP data packets (voice packets) may be offloaded.

Disabling NP4 and NP4lite hardware acceleration (fastpath)

You can use the following command to disable NP4 offloading for all traffic. This option disables NP4 offloading for all traffic for all NP4 and NP4lite processors.

```
config system npu
    set fastpath disable
end
```

Increasing NP4 offloading capacity using link aggregation groups (LAGs)

NP4 processors can offload sessions received by interfaces in link aggregation groups (LAGs) (IEEE 802.3ad). A LAG combines more than one physical interface into a group that functions like a single interface with a higher capacity than a single physical interface. For example, you could use a LAG if you want to offload sessions on a 3 Gbps link by adding three 1Gbps interfaces to the same LAG.

All offloaded traffic types are supported by LAGs, including IPsec VPN traffic. Just like with normal interfaces, traffic accepted by a LAG is offloaded by the NP4 processor connected to the interfaces in the LAG that receive the traffic to be offloaded. If all interfaces in a LAG are connected to the same NP4 processor, traffic received by that LAG is offloaded by that NP4 processor. The amount of traffic that can be offloaded is limited by the capacity of the NP4 processor.

If a FortiGate has two or more NP4 processors connected by an integrated switch fabric (ISF), you can use LAGs to increase offloading by sharing the traffic load across multiple NP4 processors. You do this by adding physical interfaces connected to different NP4 processors to the same LAG.

Adding a second NP4 processor to a LAG effectively doubles the offloading capacity of the LAG. Adding a third further increases offloading. The actual increase in offloading capacity may not actually be doubled by adding a second NP4 or tripled by adding a third. Traffic and load conditions and other factors may limit the actual offloading result.

The increase in offloading capacity offered by LAGs and multiple NP4s is supported by the ISF that allows multiple NP4 processors to share session information. On models that have more than one NP4 and no ISF, if you attempt to add interfaces connected to different NP4 processors to a LAG the system displays an error message.

There are also a few limitations to LAG NP4 offloading support for IPsec VPN:

- IPsec VPN anti-replay protection cannot be used if IPsec is configured on a LAG that has interfaces connected to multiple NP4 processors.
- Using a LAG connected to multiple NP4 processors for decrypting incoming IPsec VPN traffic may cause some of the incoming traffic to be decrypted by the CPU. So this configuration is not recommended since not all decryption is offloaded. (Using a LAG connected to multiple NP4 processors for encrypting outgoing IPsec VPN traffic is supported with no limitations.)
- Because the encrypted traffic for one IPsec VPN tunnel has the same 5-tuple, the traffic from one tunnel can only can be balanced to one interface in a LAG. This limits the maximum throughput for one IPsec VPN tunnel in an NP4 LAG group to 1Gbps.

NP4 traffic shaping offloading

Accelerated Traffic shaping is supported with the following limitations.

- NP4 processors support policy-based traffic shaping. However, fast path traffic and traffic handled by the FortiGate CPU (slow path) are controlled separately, which means the policy setting on fast path does not consider the traffic on the slow path.
- The port based traffic policing as defined by the inbandwidth and outbandwidth CLI commands is not supported.
- DSCP configurations are supported.
- Per-IP traffic shaping is supported.
- QoS in general is not supported.

You can also use the traffic shaping features of the FortiGate unit's main processing resources by disabling NP4 offloading. See [Disabling NP offloading for firewall policies on page 1250](#).

NP4 IPsec VPN offloading

NP4 processors improve IPsec tunnel performance by offloading IPsec encryption and decryption.

Requirements for hardware accelerated IPsec encryption or decryption are a modification of general offloading requirements. Differing characteristics are:

- Origin can be local host (the FortiGate unit)
- In Phase 1 configuration, Local Gateway IP must be specified as an IP address of a network interface for a port attached to a network processor
- SA must have been received by the network processor
- in Phase 2 configuration:
 - encryption algorithm must be DES, 3DES, AES-128, AES-192, AES-256, or null
 - authentication must be MD5, SHA1, or null
 - if encryption is null, authentication must not also be null

To apply hardware accelerated encryption and decryption, the FortiGate unit's main processing resources must first perform Phase 1 negotiations to establish the security association (SA). The SA includes cryptographic processing instructions required by the network processor, such as which encryption algorithms must be applied to the tunnel. After ISAKMP negotiations, the FortiGate unit's main processing resources send the SA to the network processor, enabling the network processor to apply the negotiated hardware accelerated encryption or decryption to tunnel traffic.

Possible accelerated cryptographic paths are:

- IPsec decryption offload
 - Ingress ESP packet > Offloaded decryption > Decrypted packet egress (fast path)
 - Ingress ESP packet > Offloaded decryption > Decrypted packet to FortiGate unit's main processing resources
- IPsec encryption offload
 - Ingress packet > Offloaded encryption > Encrypted (ESP) packet egress (fast path)
 - Packet from FortiGate unit's main processing resources > Offloaded encryption > Encrypted (ESP) packet egress

Configuring inter-VDOM link acceleration with NP4 processors

FortiGate units with NP4 processors include inter-VDOM links that can be used to accelerate inter-VDOM link traffic.

Traffic is blocked if you enable IPS for traffic passing over inter-VDOM links if that traffic is being offloaded by an NP4 processor. If you disable NP4 offloading traffic will be allowed to flow. You can disable offloading in individual firewall policies by disabling `auto-asic-offload` for those policies. You can also use the following command to disable all IPS offloading

```
config ips global
    set np-accel-mode none
    set cp-accel-mode none
end
```

- For a FortiGate unit with two NP4 processors there are also two inter-VDOM links, each with two interfaces:

- **npu0-vlink:**

npu0-vlink0
npu0-vlink1

- **npu1-vlink:**

npu1-vlink0
npu1-vlink1

These interfaces are visible from the GUI and CLI. For a FortiGate unit with NP4 interfaces, enter the following CLI command (output shown for a FortiGate-5001B):

```
get hardware npu np4 list
ID      Model      Slot      Interface
0       On-board
        port1 port2 port3 port4
        fabric1 base1 npu0-vlink0 npu0-vlink1
1       On-board
        port5 port6 port7 port8
        fabric2 base2 npu1-vlink0 npu1-vlink1
```

By default the interfaces in each inter-VDOM link are assigned to the root VDOM. To use these interfaces to accelerate inter-VDOM link traffic, assign each interface in a pair to the VDOMs that you want to offload traffic between. For example, if you have added a VDOM named New-VDOM to a FortiGate unit with NP4 processors, you can go to **System > Network > Interfaces** and edit the **npu0-vlink1** interface and set the **Virtual Domain** to **New-VDOM**.

This results in an inter-VDOM link between root and New-VDOM. You can also do this from the CLI:

```
config system interface
  edit npu0-vlink1
    set vdom New-VDOM
  end
```

Using VLANs to add more accelerated inter-VDOM links

You can add VLAN interfaces to the accelerated inter-VDOM links to create inter-VDOM links between more VDOMs. For the links to work, the VLAN interfaces must be added to the same inter-VDOM link, must be on the same subnet, and must have the same VLAN ID.

For example, to accelerate inter-VDOM link traffic between VDOMs named Marketing and Engineering using VLANs with VLAN ID 100 go to **System > Network > Interfaces** and select **Create New** to create the VLAN interface associated with the Marketing VDOM:

Name	Marketing-link
Type	VLAN
Interface	npu0-vlink0
VLAN ID	100
Virtual Domain	Marketing
IP/Network Mask	172.20.120.12/24

Create the inter-VDOM link associated with Engineering VDOM:

Name	Engineering-link
Type	VLAN
Interface	npu0-vlink1
VLAN ID	100
Virtual Domain	Engineering
IP/Network Mask	172.20.120.22/24

Or do the same from the CLI:

```

config system interface
  edit Marketing-link
    set vdom Marketing
    set ip 172.20.120.12/24
    set interface npu0-vlink0
    set vlanid 100
  next
  edit Engineering-link
    set vdom Engineering
    set ip 172.20.120.22/24
    set interface npu0-vlink1
    set vlanid 100

```

Confirm that the traffic is accelerated

Use the following CLI commands to obtain the interface index and then correlate them with the session entries. In the following example traffic was flowing between new accelerated inter-VDOM links and physical ports port1 and port 2 also attached to the NP4 processor.

diagnose ip address list

```

IP=172.31.17.76->172.31.17.76/255.255.252.0 index=5 devname=port1
IP=10.74.1.76->10.74.1.76/255.255.252.0 index=6 devname=port2
IP=172.20.120.12->172.20.120.12/255.255.255.0 index=55 devname=IVL-VLAN1_ROOT
IP=172.20.120.22->172.20.120.22/255.255.255.0 index=56 devname=IVL-VLAN1_VDOM1

```

diagnose sys session list

```

session info: proto=1 proto_state=00 duration=282 expire=24 timeout=0 session info:

```

Offloading NP4 anomaly detection

Network interfaces associated with a port attached to an NP4 processor can be configured to offload anomaly checking to the NP4 processor. This anomaly checking happens before other offloading and separately from DoS policy anomaly checking. Using the following command, each FortiGate interface can have a different anomaly checking configuration even if they are connected to the same NP4 processor.

The options available for this command apply anomaly checking for NP4 sessions in the same way as the command described in [Configuring individual NP6 processors on page 1265](#) applies anomaly checking for NP6 sessions.

```
config system interface
  edit <port-name>
    set fp-anomaly <anomalies>
  end
```

where <anomalies> can be one, more than one or all of the following:

Anomaly	Description
drop_icmp_frag	Drop ICMP fragments to pass.
drop_icmpland	Drop ICMP Land.
drop_ipland	Drop IP Land.
drop_iplsrr	Drop IP with Loose Source Record Route option.
drop_iprr	Drop IP with Record Route option.
drop_ipsecurity	Drop IP with Security option.
drop_ipssrr	Drop IP with Strict Source Record Route option.
drop_ipstream	Drop IP with Stream option.
drop_iptimestamp	Drop IP with Timestamp option.

Anomaly	Description
drop_ipunknown_option	Drop IP with malformed option.
drop_ipunknown_prot	Drop IP with Unknown protocol.
drop_tcp_fin_noack	Drop TCP FIN with no ACK flag set to pass.
drop_tcp_no_flag	Drop TCP with no flag set to pass.
drop_tcpland	Drop TCP Land.
drop_udpland	Drop UDP Land.
drop_winnuke	Drop TCP WinNuke.
pass_icmp_frag	Allow ICMP fragments to pass.
pass_icmpland	Allow ICMP Land to pass.
pass_ipland	Allow IP land to pass.
pass_iplsrr	Allow IP with Loose Source Record Route option to pass.
pass_iprr	Allow IP with Record Route option to pass.
pass_ipsecurity	Allow IP with Security option to pass.
pass_ipssrr	Allow IP with Strict Source Record Route option to pass.
pass_ipstream	Allow IP with Stream option to pass.
pass_iptimestamp	Allow IP with Timestamp option to pass.
pass_ipunknown_option	Allow IP with malformed option to pass.
pass_ipunknown_prot	Allow IP with Unknown protocol to pass.

Anomaly	Description
pass_tcp_fin_noack	Allow TCP FIN with no ACT flag set to pass.
pass_tcp_no_flag	Allow TCP with no flag set to pass.
pass_tcpland	Allow TCP Land to pass.
pass_udpland	Allow UDP Land to pass.
pass_winnuke	Allow TCP WinNuke to pass.

Example

You might configure an NP4 to drop packets with TCP WinNuke or unknown IP protocol anomalies, but to pass packets with an IP time stamp, using hardware acceleration provided by the network processor.

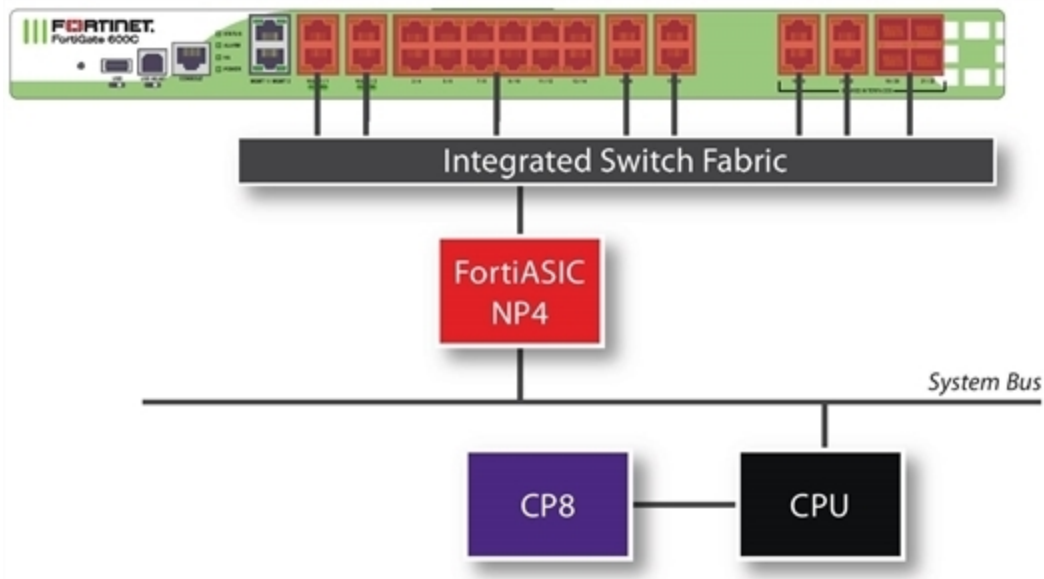

```
config system interface
  edit port1
    set fp-anomaly drop_winnuke drop_ipunknown_prot pass_iptimestamp
  end
```

FortiGate NP4 architectures

This chapter shows the NP4 architecture for the all FortiGate models that include NP4 processors.

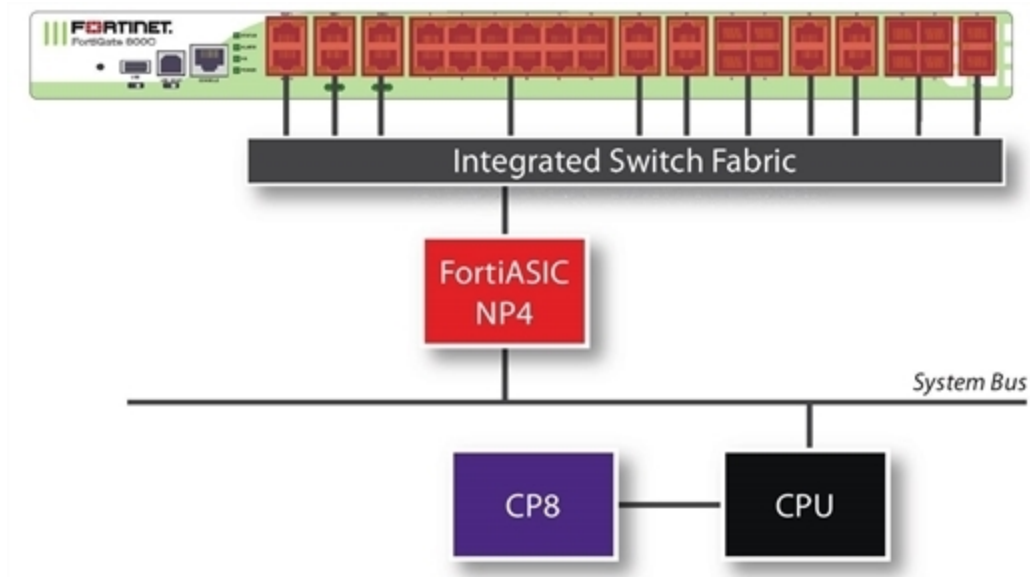

FortiGate-600C

The FortiGate-600C features one NP4 processor. All the ports are connected to this NP4 over the Integrated Switch Fabric. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are four 1Gb SFP interface ports duplicating the port19-port22 connections.

FortiGate-800C

The FortiGate-800C features one NP4 processor. All the ports are connected to this NP4. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 Ethernet ports, and there are eight 1Gb SFP interface ports duplicating the port15-18 and port19-port22 connections. There are also two 10Gb SFP+ ports, port23 and port24.

FortiGate-1000C

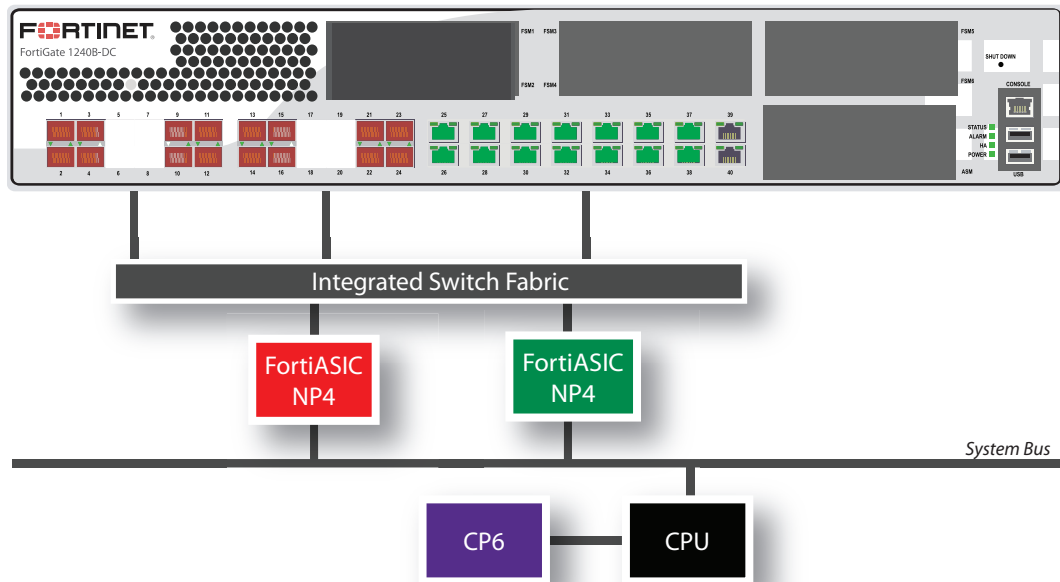

The FortiGate-1000C features one NP4 processor. All the ports are connected to this NP4. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are eight 1Gb SFP interface ports duplicating the port15-18 and port19-port22 connections. There are also two 10Gb SFP+ ports, port23 and port24.

FortiGate-1240B

The FortiGate-1240B features two NP4 processors:

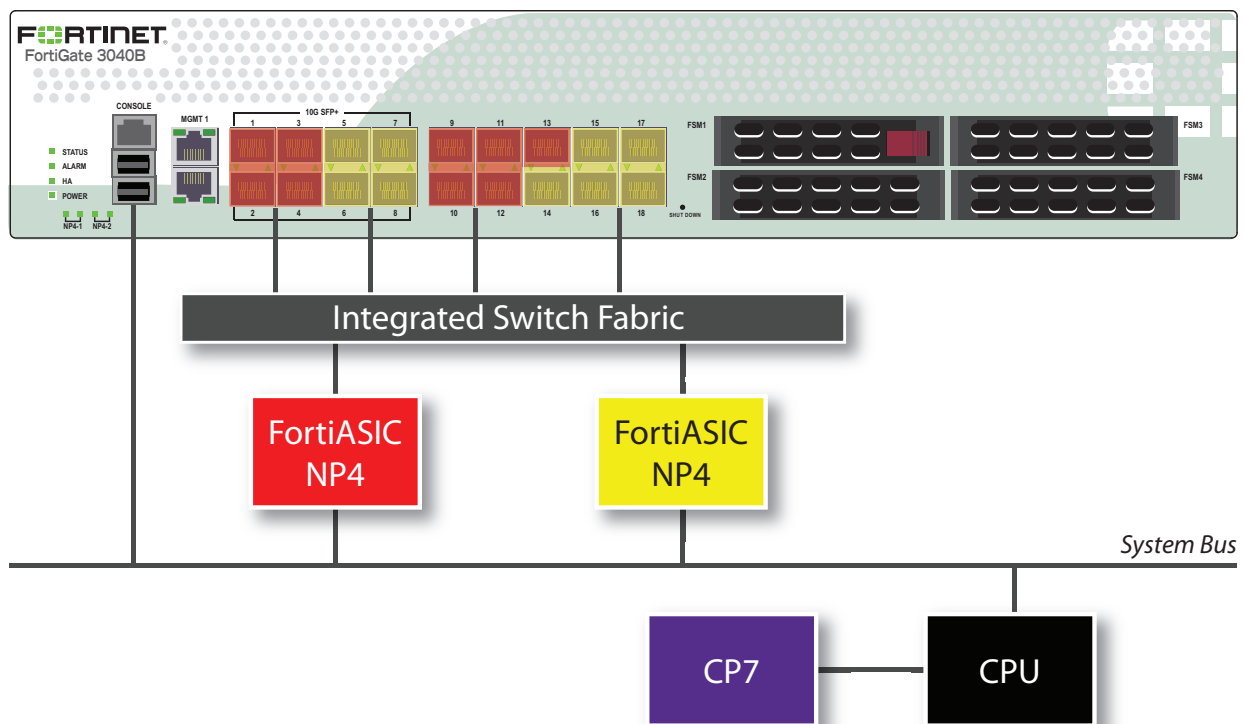

- Port1 to port24 are 1Gb SFP interfaces connected to one NP4 processor.
- Port25 to port38 are RJ-45 ethernet ports, connected to the other NP4 processor.
- Port39 and port40 are not connected to an NP4 processor.

FortiGate-3040B

The FortiGate-3040B features two NP4 processors:

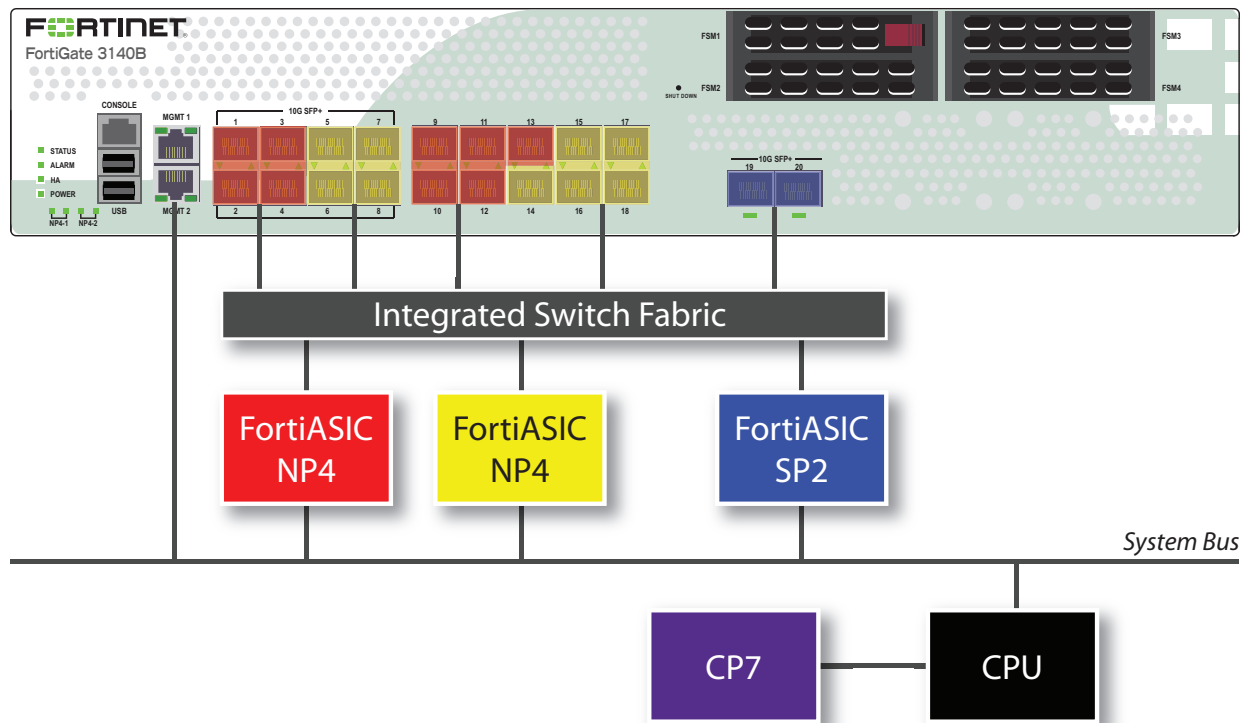

- The 10Gb interfaces, port1, port2, port3, port4, and the 1Gb interfaces, port9, port10, port11, port12, port13, share connections to one NP4 processor.
- The 10Gb interfaces, port5, port6, port7, port8, and the 1Gb interfaces, port14, port15, port16, port17, port18, share connections to the other NP4 processor.

FortiGate-3140B

The FortiGate-3140B features two NP4 processors and one SP2 processor:

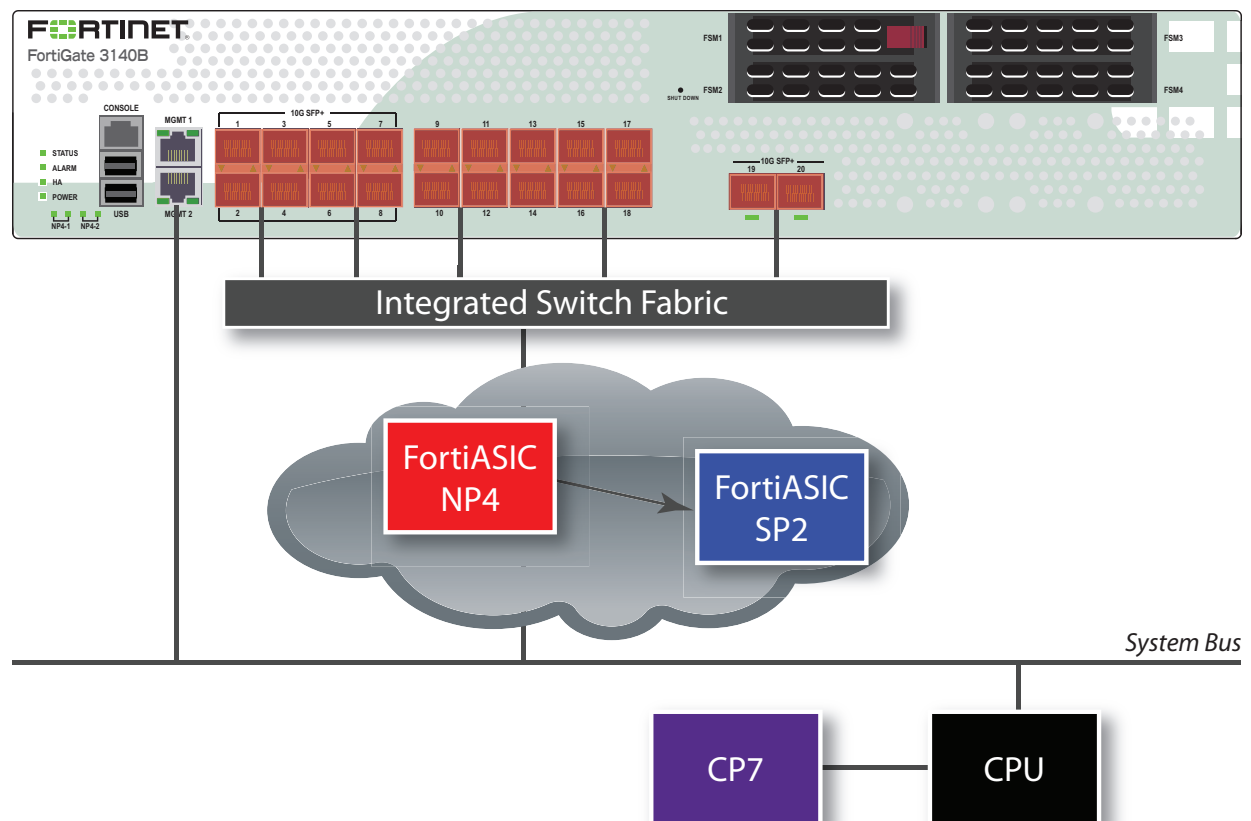

- The 10Gb interfaces, port1, port2, port3, port4, and the 1Gb interfaces, port9, port10, port11, port12, port13, share connections to one NP4 processor.
- The 10Gb interfaces, port5, port6, port7, port8, and the 1Gb interfaces, port14, port15, port16, port17, port18, share connections to the other NP4 processor.
- The 10Gb interfaces, port19 and port20, share connections to the SP2 processor.

FortiGate-3140B — load balance mode

The FortiGate-3140B load balance mode allows you increased flexibility in how you use the interfaces on the FortiGate unit. When enabled, traffic between any two interfaces (excluding management and console) is accelerated. Traffic is not limited to entering and leaving the FortiGate unit in specific interface groupings to benefit from NP4 and SP2 acceleration. You can use any pair of interfaces.

Security acceleration in this mode is limited, however. Only IPS scanning is accelerated in load balance mode.

To enable this feature, issue this CLI command.

```
config system global
    set sp-load-balance enable
end
```

The FortiGate unit will then restart.

To return to the default mode, issue this CLI command.

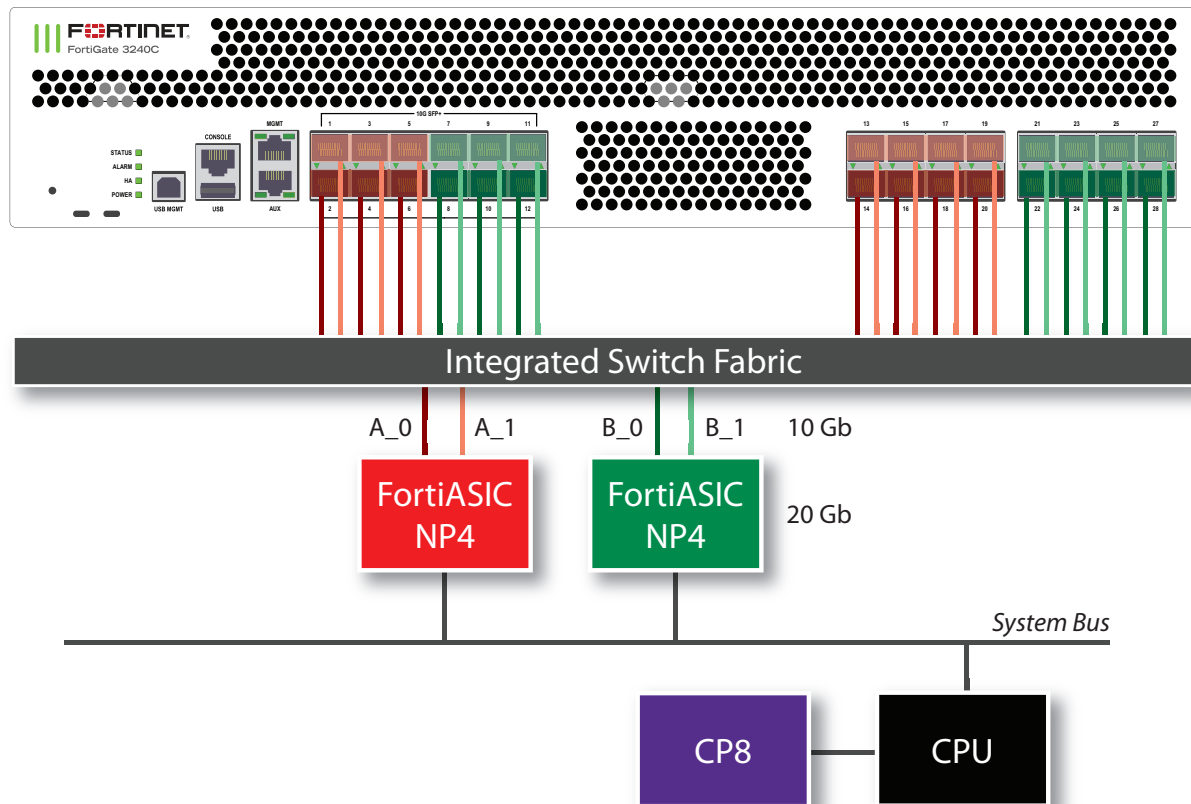

```
config system global
    set sp-load-balance disable
end
```

FortiGate-3240C

The FortiGate-3240C features two NP4 processors:

- The 10Gb interfaces, port1 through port6, and the 1Gb interfaces, port13 through port20, share connections to one NP4 processor.
- The 10Gb interfaces, port7 through port12, and the 1Gb interfaces, port21 through port28, share connections to the other NP4 processor.

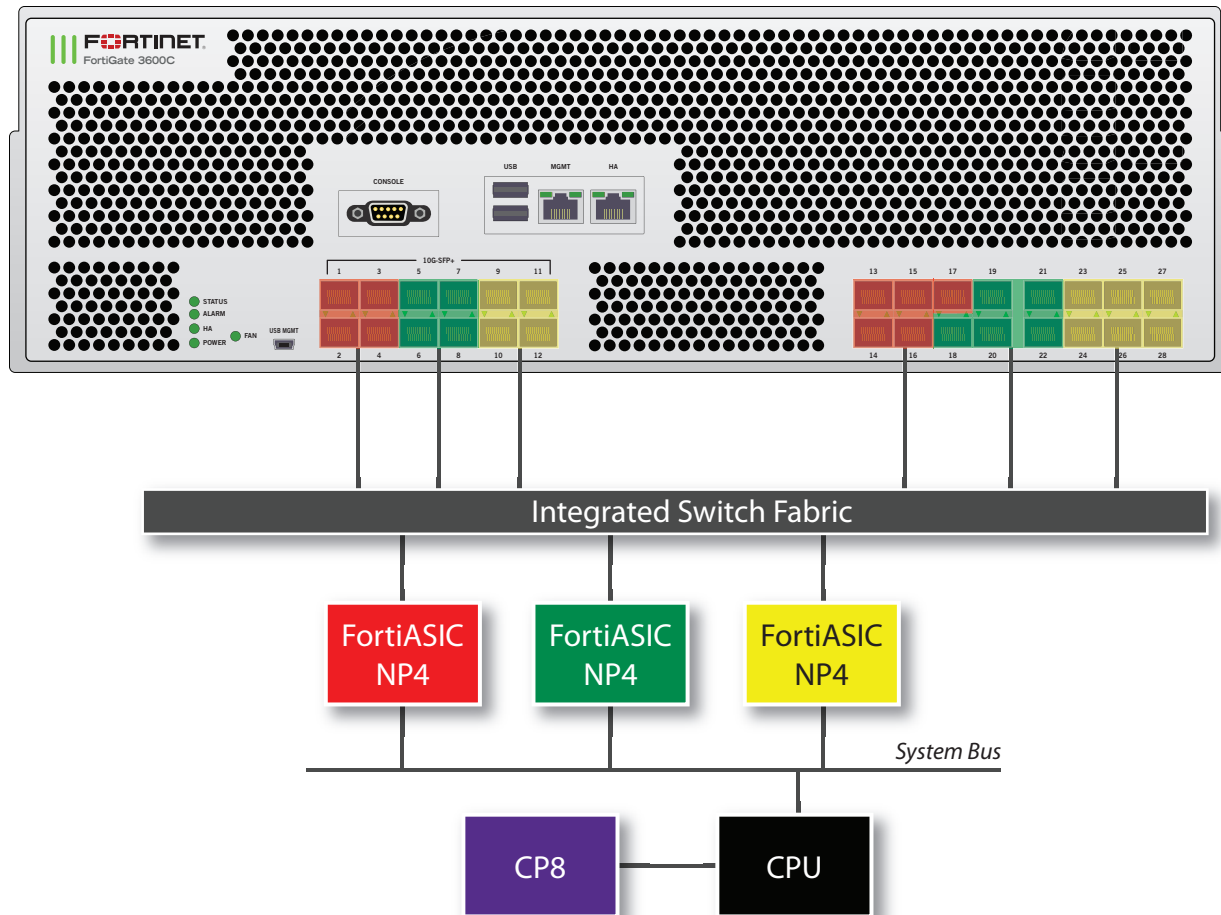

In addition to the ports being divided between the two NP4 processors, they are further divided between the two connections to each processor. Each NP4 can process 20 Gb of network traffic per second and each of two connections to each NP4 can move 10Gb of data to the processor per second, so the ideal configuration would have no more than 10 Gb of network traffic to each connection of each NP4 at any time.

FortiGate-3600C

The FortiGate-3600C features three NP4 processors:

- The 10Gb interfaces, port1-port4, and the 1Gb interfaces, port13-port17, share connections to one NP4 processor.
- The 10Gb interfaces, port5-port8, and the 1Gb interfaces, port18-port22 share connections to the second NP4 processor.
- The 10Gb interfaces, port9-port12, and the 1Gb interfaces, port23-port28 share connections to the third NP4 processor.

FortiGate-3600C XAUI links

The FortiGate-3600C uses XAUI links for communication between physical Ethernet ports and the integrated switch fabric.

Each XAUI link has a maximum bandwidth of 10-Gigabits. The reason you may need to know about the XAUI link in NP4 configurations is because of this 10-Gigabit limit. Because of this limitation, the total amount of data processed by all Ethernet interfaces connected to an XAUI link cannot exceed 10 gigabits. In some cases this may limit the amount of bandwidth that the FortiGate can process.

Each NP4 processor connects to the integrated switch fabric through two XAUI links: XAUI0 and XAUI1. All of the odd numbered Ethernet interfaces use XAUI0 and all of the even numbered interfaces use XAUI1:

NPU1

XAUI0 = port1, port3, port13, port15, port17

XAUI1 = port2, port4, port14, port16

NPU2

XAUI0 = port5, port7, port18, port20, port22

XAUI1 = port6, port8, port19, port21

NPU3

XAUI0 = port9, port11, port23, port25, port27

XAUI1 = port10, port12, port24, port26, port28

Usually you do not have to be concerned about XAUI link mapping. However, if a FortiGate-3600C NP4 interface is processing a very high amount of traffic you should distribute that traffic among both of the XAUI links connected to it. So if you have a very high volume of traffic flowing between two networks you should connect both networks to the same NP4 processor but to different XAUI links. For example, you could connect one network to Ethernet port5 and the other network to Ethernet port6. In this configuration, the second NP4 processor would handle traffic acceleration and both XAUI links would be processing traffic.

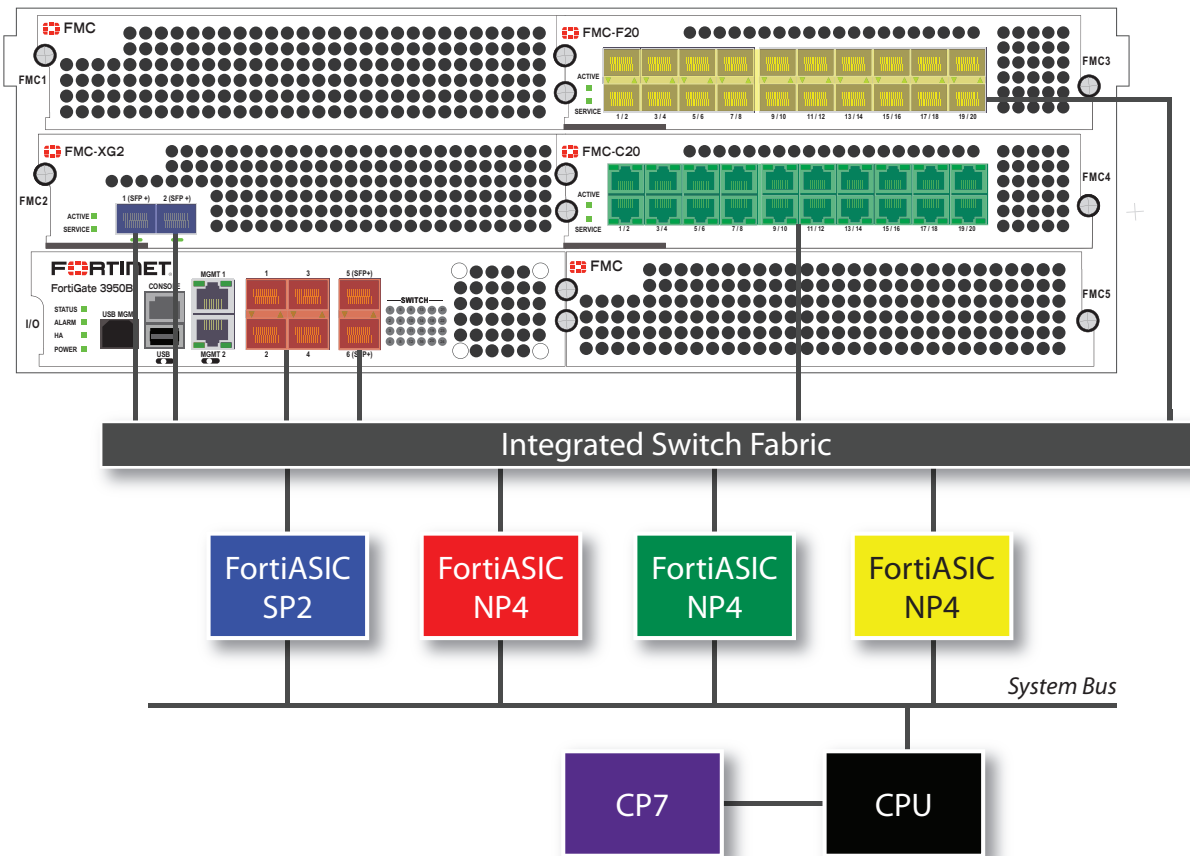

FortiGate-3950B and FortiGate-3951B

The FortiGate-3950B features one NP4 processor. The 1Gb SPF interfaces, port1, port2, port3, port4, and the 10Gb SPF+ interfaces, port5, port6, share connections to one NP4 processor. The FortiGate-3951B is similar to the FortiGate-3950B, except it trades one FMC slot for four FSM slots. The network interfaces available on each model are identical.

You can add additional FMC interface modules. The diagram below shows a FortiGate-3950B with three modules installed: an FMC-XG2, an FMC-F20, and an FMC-C20.

- The FMC-XG2 has one SP2 processor. The 10Gb SPF+ interfaces, port1 and port2, share connections to the processor.
- The FMC-F20 has one NP4 processor and the twenty 1Gb SPF interfaces, port1 through port20, share connections to the NP4 processor.

- The FMC-C20 has one NP4 processor and the twenty 10/100/1000 interfaces, port1 through port20, share connections to the NP4 processor.

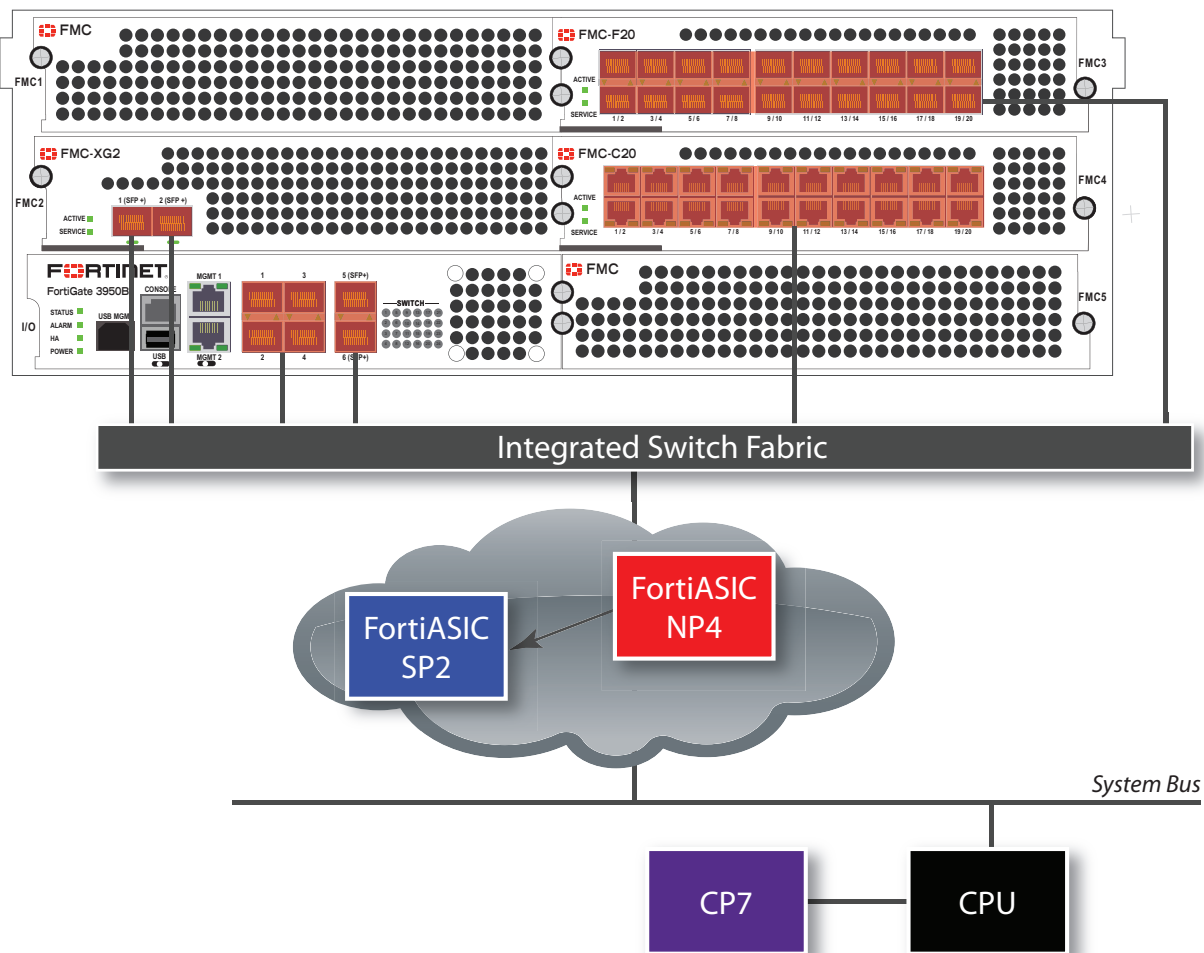

FortiGate-3950B and FortiGate-3951B — load balance mode

Adding one or more FMC-XG2 modules to your FortiGate-3950B allows you to enable load balance mode. This feature allows you increased flexibility in how you use the interfaces on the FortiGate unit. The FortiGate-3951B is similar to the FortiGate-3950B, except it trades one FMC slot for four FSM slots. The network interfaces available on each model are identical.

When enabled, traffic between any two interfaces (excluding management and console) is accelerated whether they are the six interfaces on the FortiGate-3950B itself, or on any installed FMC modules. Traffic is not limited to entering and leaving the FortiGate unit in specific interface groupings to benefit from NP4 and SP2 acceleration. You can use any pair of interfaces.

Security acceleration in this mode is limited, however. Only IPS scanning is accelerated in load balance mode.

The FortiGate-3950B in load balance mode

To enable this feature, issue this CLI command.

```
config system global
    set sp-load-balance enable
end
```

The FortiGate unit will then restart.

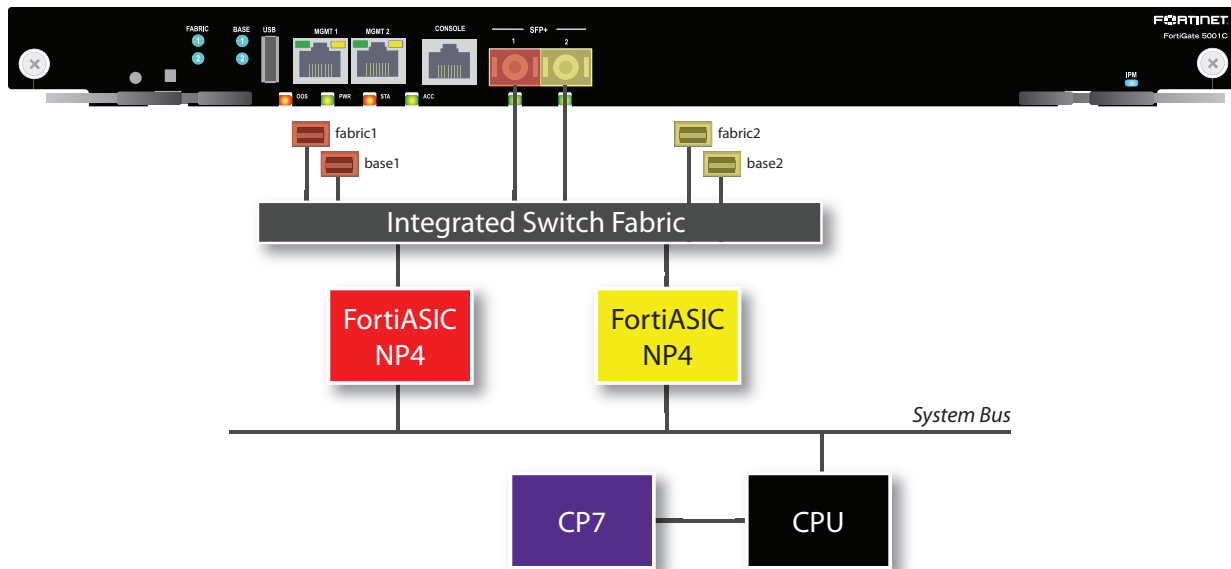

To return to the default mode, issue this CLI command.

```
config system global
    set sp-load-balance disable
end
```

FortiGate-5001C

The FortiGate-5001C board includes two NP4 processors connected to an integrated switch fabric:

- The port1, fabric1, and base1 interfaces are connected to one NP4 processor.
- The port2, fabric2, and base2 interfaces are connected to the other NP4 processor.

FortiGate-5001B

The FortiGate-5001B board includes two NP4 connected to an integrated switch fabric.

- The port1, port2, port3, port4, fabric1 and base1 interfaces are connected to one NP4 processor.
- The port5, port6, port7, port8, fabric2 and base2 interfaces are connected to the other NP4 processor.

Setting switch-mode mapping on the ADM-XD4

The ADM-XD4 SP has four 10Gb/s ports, but the NP4 processor it contains has only two 10Gb/s ports. The external ports you use are important to optimize the SP for your application.

ADM-XD4 mapping mode

Ports 1 and 3 share one NP4 processor and ports 2 and 4 share the other. Performance ports sharing the same NP4 processor is far better than when forcing network data to move between NP4 processors by using one port from each, for example ports 1 and 2 or ports 3 and 4.

Hardware acceleration get and diagnose commands

This section describes some `get` and `diagnose` commands you can use to display useful information about the NP6 processors sessions processed by NP6 processors.

get hardware npu np6

You can use the `get hardware npu np6` command to display information about the NP6 processors in your FortiGate and the sessions they are processing. This command contains a subset of the options available from the `diagnose npu np6` command. The command syntax is:

```
get hardware npu np6 {dce <np6-id> | ipsec-stats | port-list | session-stats <np6-id> |  
sse-stats <np6-id> | synproxy-stats}
```

`<np6-id>` identifies the NP6 processor. 0 is `np6_0`, 1 is `np6_1` and so on.

`dce` show NP6 non-zero sub-engine drop counters for the selected NP6.

`ipsec-stats` show overall NP6 IPsec offloading statistics.

`port-list` show the mapping between the FortiGate physical interfaces and NP6 processors.

`session-stats` show NP6 session offloading statistics counters for the selected NP6.

`sse-stats` show hardware session statistics counters.

`synproxy-stats` show overall NP6 synproxy statistics for TCP connections identified as being syn proxy DoS attacks.

diagnose npu np6

The `diagnose npu np6` command displays extensive information about NP6 processors and the sessions that they are processing. Some of the information displayed can be useful for understanding the NP6 configuration, seeing how sessions are being processed and diagnosing problems. Some of the commands may only be useful for Fortinet software developers. The command syntax is:

```
diagnose npu np6 {options}
```

The following options are available:

`fastpath {disable | enable} <np6-od>` enable or disable fastpath processing for a selected NP6.

`dce` shows NP6 non-zero sub-engine drop counters for the selected NP6.

`dce-all` show all subengine drop counters.

`anomaly-drop` show non-zero L3/L4 anomaly check drop counters.

`anomaly-drop-all` show all L3/L4 anomaly check drop counters.

`hrx-drop` show non-zero host interface drop counters.

`hrx-drop-all` show all host interface drop counters.

`session-stats` show session offloading statistics counters.

`session-stats-clear` clear session offloading statistics counters.

`sse-stats` show hardware session statistics counters.

`sse-stats-clear` show hardware session statistics counters.

`pdq` show packet buffer queue counters.

`xgmac-stats` show XGMAC MIBs counters.

`xgmac-stats-clear` clear XGMAC MIBS counters.

`port-list` show port list.

`ipsec-stats` show IPsec offloading statistics.

`ipsec-stats-clear` clear IPsec offloading statistics.

`EEPROM-read` read NP6 EEPROM.

`npu-feature` show NPU feature and status.

`register` show NP6 registers.

`fortilink` configure managed FortiSwitch.

`synproxy-stats` show synproxy statistics.

Using diagnose npu np6 npu-feature to verify enabled NP6 features

You can use the `diagnose npu np6 npu-feature` command to see what NP6 features are enabled and which are not. The following command output shows the normal default NP6 configuration for most FortiGates. In this output all features are enabled except low latency features and GRE offloading. Low latency is only available on the FortiGate-3700D and DX models and GRE offloading will become available in a future FortiOS release. The following output is from a FortiGate-1500D

```
diagnose npu np6 npu-feature
-----
```

	np_0	np_1
Fastpath	Enabled	Enabled
Low-latency-mode	Disabled	Disabled
Low-latency-cap	No	No
IPv4 firewall	Yes	Yes
IPv6 firewall	Yes	Yes
IPv4 IPsec	Yes	Yes
IPv6 IPsec	Yes	Yes
IPv4 tunnel	Yes	Yes
IPv6 tunnel	Yes	Yes
GRE tunnel	No	No
IPv4 Multicast	Yes	Yes
IPv6 Multicast	Yes	Yes
CAPWAP	Yes	Yes

If you use the following command to disable fastpath for np_0:

```
config system np6
  edit np6_0
    set fastpath disable
  end
```

The `npu-feature` command output show this configuration change:

```
diagnose npu np6 npu-feature
-----
np_0      np_1
-----
Fastpath      Disabled  Enabled
Low-latency-mode Disabled  Disabled
Low-latency-cap No        No
IPv4 firewall Yes       Yes
IPv6 firewall Yes       Yes
IPv4 IPsec    Yes       Yes
IPv6 IPsec    Yes       Yes
IPv4 tunnel   Yes       Yes
IPv6 tunnel   Yes       Yes
GRE tunnel    No        No
IPv4 Multicast Yes       Yes
IPv6 Multicast Yes       Yes
CAPWAP        Yes       Yes
```

Using the diagnose sys session/session6 list command

The `diagnose sys session list` and `diagnose sys session6 list` commands list all of the current IPv4 or IPv6 sessions being processed by the FortiGate. For each session the command output includes an `npu info` line that displays NPx offloading information for the session. If a session is not offloaded the command output includes a `no_ofld_reason` line that indicates why the session was not offloaded.

Displaying NP6 offloading information for a session

The `npu info` line of the `diagnose sys session list` command includes information about the offloaded session that indicates the type of processor and whether its IPsec or regular traffic:

- `offload=1/1` for NP1(FA1) sessions.
- `offload=2/2` for NP1(FA2) sessions.
- `offload=3/3` for NP2 sessions.
- `offload=4/4` for NP4 sessions.
- `offload=5/5` for XLR sessions.
- `offload=6/6` for NPlite/NP4lite sessions.
- `offload=7/7` for XLP sessions.
- `offload=8/8` for NP6 sessions.
- `flag 0x81` means regular traffic.
- `flag 0x82` means IPsec traffic.

Example offloaded IPv4 NP6 session

The following session output by the `diagnose sys session list` command shows an offloaded session. The information in the `npu info` line shows this is a regular session (`flag=0x81/0x81`) that is offloaded by an NP6 processor (`offload=8/8`).

```
diagnose sys session list
session info: proto=6 proto_state=01 duration=4599 expire=2753 timeout=3600 flags-
s=00000000 sockflag=00000000 sockport=0 av_idx=0 use=3
origin-shaper=
```

```

diagnose npu np6 session-stats <np6-id> (number of NP6 IPv4 and IPv6 sessions)

You can use the `diagnose npu np6 portlist` command to list the NP6-ids and the interfaces that each NP6 is connected to. The <np6-id> of np6_0 is 0, the <np6-id> of np6_1 is 1 and so on. The `diagnose npu np6 session-stats <np6-id>` command output includes the following headings:

- ins44 installed IPv4 sessions
- ins46 installed NAT46 sessions
- del4 deleted IPv4 and NAT46 sessions
- ins64 installed NAT64 sessions
- ins66 installed IPv6 sessions
- del6 deleted IPv6 and NAT64 sessions
- e is the error counter for each session type

```

diagnose npu np6 session-stats 0

diagnose sys mcast-session/session6 list (IPv4 and IPv6 multicast sessions)

This command lists all IPv4 or IPv6 multicast sessions. If a multicast session can be offloaded, the output includes the `offloadable` tag. If the multicast path can be offloaded one of the paths in the command output is tagged as `offloaded`.

The only way to determine the number of offloaded multicast sessions is to use the `diagnose sys mcast-session/session6 list` command and count the number of sessions with the `offload` tag.

```
diagnose sys mcast-session list
session info: id=3 vf=0 proto=17 172.16.200.55.51108->239.1.1.1.7878
used=2 path=11 duration=1 expire=178 indev=6 pkts=2 state:2cpu offloadable
npn-info in-pid=0 vifid=0 in-vtag=0 npuid=0 queue=0 tae=0

path: 2cpu policy=1, outdev=2
      out-vtag=0
path: 2cpu policy=1, outdev=3
      out-vtag=0
path: offloaded policy=1, outdev=7
      out-vtag=0
path: policy=1, outdev=8
      out-vtag=0
path: policy=1, outdev=9
      out-vtag=0
path: policy=1, outdev=10
      out-vtag=0
path: policy=1, outdev=11
      out-vtag=0
path: policy=1, outdev=12
      out-vtag=0
path: policy=1, outdev=13
      out-vtag=0
path: 2cpu policy=1, outdev=64
      out-vtag=0
path: 2cpu policy=1, outdev=68
      out-vtag=0
```

diagnose npu np6 sse-stats <np6-id> (number of NP6 sessions and dropped sessions)

This command displays the total number of inserted, deleted and purged sessions processed by a selected NP6 processor. The number of dropped sessions of each type can be determined by subtracting the number of successful sessions from the total number of sessions. For example, the total number of dropped insert sessions is `insert-total - insert-success`.

```
diagnose npu np6 sse-stats 0
```

Counters	SSE0	SSE1	Total
active	0	0	0
insert-total	25	0	0
insert-success	25	0	0
delete-total	25	0	0
delete-success	25	0	0
purge-total	0	0	0
purge-success	0	0	0
search-total	40956	38049	79005
search-hit	37714	29867	67581
pht-size	8421376	8421376	
oft-size	8355840	8355840	
oftfree	8355839	8355839	
PBA	3001		

diagnose npu np6 dce <np6-id> (number of dropped NP6 packets)

This command displays the number of dropped packets for the selected NP6 processor.

- `IHP1_PKTCHK` number of dropped IP packets
- `IPSEC0_ENGINB0` number of dropped IPSec
- `TPE_SHAPER` number of dropped traffic sharper packets

```
diag npu np6 dce 1
IHP1_PKTCHK :00000000000001833 [5b] IPSEC0_ENGINB0 :0000000000000003 [80]
TPE_SHAPER :00000000000000552 [94]
```

diagnose hardware deviceinfo nic <interface-name> (number of packets dropped by an interface)

This command displays a wide variety of statistics for FortiGate interfaces. The fields `Host Rx dropped` and `Host Tx dropped` display the number of received and transmitted packets that have been dropped.

```
diagnose hardware deviceinfo nic port2
```

```
...
```

```
===== Counters =====
```

```
Rx Pkts           :20482043
Rx Bytes          :31047522516

diagnose npu np6 synproxy-stats (NP6 SYN-proxied sessions and unacknowledged SYNs)

This command displays information about NP6 syn-proxy sessions including the total number proxied sessions. As well the Number of attacks, no ACK from client shows the total number of acknowledged SYNs.

```
diagnose npu np6 synproxy-stats
DoS SYN-Proxy:
Number of proxied TCP connections : 39277346
Number of working proxied TCP connections : 182860
Number of retired TCP connections : 39094486
Number of attacks, no ACK from client : 208
```

Chapter 12 - High Availability

This FortiOS Handbook chapter contains the following sections:

[Solving the high availability problem](#) describes the high availability problem and introduces the FortiOS solutions described in this document (FGCP, VRRP, and standalone session synchronization).

[An introduction to the FGCP](#) introduces the FGCP clustering protocol and many of its features and terminology.

[FGCP configuration examples and troubleshooting](#) describes configuring HA clusters and contains HA clustering configuration examples.

[Virtual clusters](#) describes configuring HA virtual clusters and contains virtual clustering configuration examples.

[Full mesh HA](#) describes configuring FortiGate Full mesh HA and contains a full mesh HA configuration example.

[Operating clusters and virtual clusters](#) describes how to operate a cluster and includes detailed information about how various FortiGate systems operate differently in a cluster.

[HA and failover protection](#) describes in detail how FortiGate HA device failover, link failover, and session failover work.

[HA and load balancing](#) describes how FGCP HA active-active load balancing works and how to configure it.

[HA with FortiGate-VM and third-party products](#) describes how FortiGates interact with third-party products.

[VRRP high availability](#) describes FortiOS support of the Virtual Router Redundancy Protocol (VRRP) and its use for high availability.

[FortiGate Session Life Support Protocol \(FGSP\)](#) describes how to use the FGSP feature to support using external routers or load balancers to distribute or load balance sessions between two peer FortiGates.

What's new in FortiOS 6.0

The following list contains new high availability features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- Changes to get `system status ha` command output, see [Viewing cluster status from the CLI on page 1511](#)
- IPv6 support for VRRP, see [VRRP high availability on page 1595](#)
- [Session synchronization between FGCP clusters on page 1608](#)
- [GTP session synchronization: FGSP for FortiOS Carrier on page 1615](#)
- FGSP configuration synchronization changes, see [Synchronizing the configuration on page 1611](#)
- FGSP restoring a configuration is not synchronized, see [Backing up and restoring the configuration of an FGSP cluster on page 1613](#).
- New diagnose commands to find synchronization details, see [Determining what is causing a configuration synchronization problem on page 1545](#)
- HA IPv6 remote link monitoring, see [Configuring IPv6 remote IP monitoring on page 1558](#)

Solving the high availability problem

The basic high availability (HA) problem for TCP/IP networks and security gateways is keeping network traffic flowing. Uninterrupted traffic flow is a critical component for online systems and media because critical business processes quickly come to a halt when the network is down.

The security gateway is a crucial component of most networks since all traffic passes through it. A standalone network security gateway is a single point of failure that is vulnerable to any number of software or hardware problems that could compromise the device and bring all traffic on the network to a halt.

A common solution to the high availability problem is to eliminate the security gateway as single point of failure by introducing redundancy. With two or more redundant security gateways, if one fails, the remaining one or more gateways keep the traffic flowing. FortiOS provides six redundancy solutions: industry standard VRRP as well as five proprietary solutions: FortiGate Cluster Protocol (FGCP) high availability, FortiGate Session Life Support Protocol (FGSP) high availability, Session-Aware Load Balancing Clustering (SLBC), Enhanced Load Balanced Clustering (ELBC) and Content Clustering.

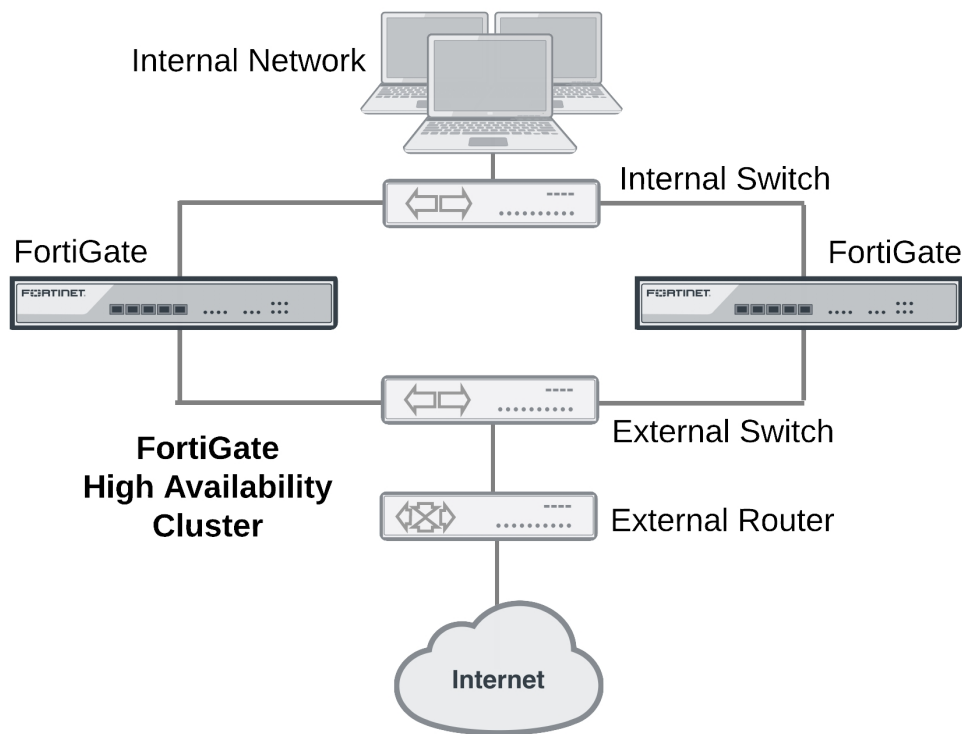

You can combine more than one high availability solution into a single configuration. A common reason for doing this could be to add VRRP to an FGCP or FGSP configuration.

A strong and flexible High availability solution is required for many mission-critical firewall and security profile applications. Each FortiOS high availability solution can be fine tuned to fit into many different network scenarios.

FortiGate Cluster Protocol (FGCP)

FGCP HA provides a solution for two key requirements of critical enterprise networking components: enhanced reliability and increased performance. Enhanced reliability is achieved through device failover protection, link failover protection and remote link failover protection. Also contributing to enhanced reliability is session failover protection for most IPv4 and IPv6 sessions including TCP, UDP, ICMP, IPsec VPN, and NAT sessions. Increased performance is achieved through active-active HA load balancing. Extended FGCP features include full mesh HA and virtual clustering. You can also fine tune the performance of the FGCP to change how a cluster forms and shares information among cluster units and how the cluster responds to failures.

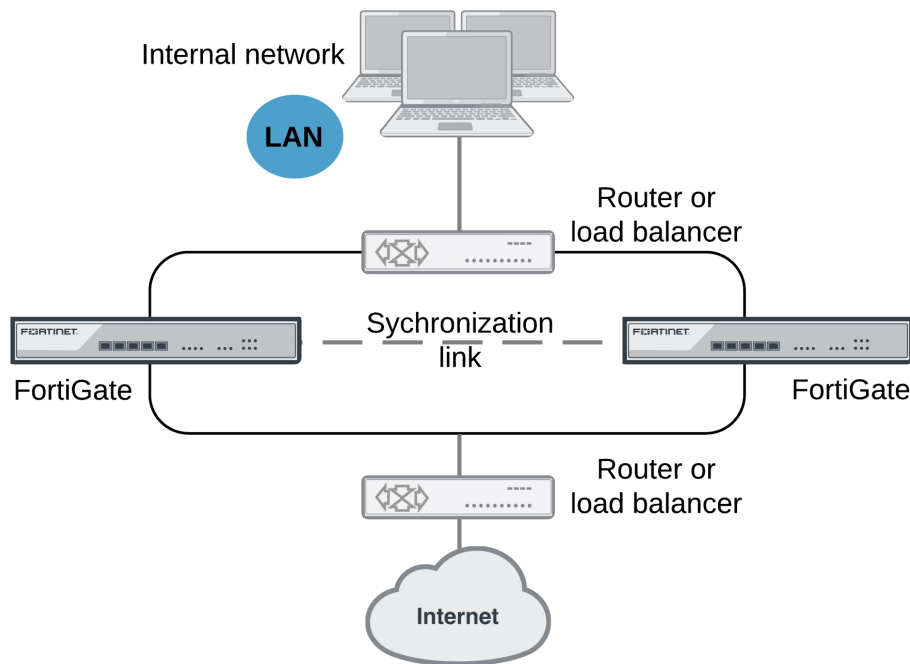

When configured onto your network an FGCP cluster appears to be a single FortiGate operating in NAT/Route or transparent mode and configuration synchronization allows you to configure a cluster in the same way as a standalone FortiGate. If a failover occurs, the cluster recovers quickly and automatically and also sends administrator notifications so that the problem that caused the failure can be corrected and any failed equipment restored.

The FGCP is compatible with most network environments and most networking equipment. While initial configuration is relatively quick and easy, a large number of tools and configuration options are available to fine tune the cluster for most situations.

FortiGate Session Life Support Protocol (FGSP)

In a network that already includes load balancing (either with load balancers or routers) for traffic redundancy, two identical FortiGates can be integrated into the load balancing configuration using the FortiGate Session Life Support Protocol (FGSP). The external load balancers or routers can distribute sessions among the FortiGates and the FGSP performs session synchronization of IPv4 and IPv6 TCP, SCTP, UDP, ICMP, expectation, and NAT sessions to keep the session tables of both FortiGates synchronized.

If one of the FortiGates fails, session failover occurs and active sessions fail over to the unit that is still operating. This failover occurs without any loss of data. As well, the external load balancers or routers detect the failover and re-distribute all sessions to the unit that is still operating.

Load balancing and session failover is done by external routers or load balancers and not by the FGSP. The FortiGates just perform session synchronization which allows session failover to occur without packet loss.

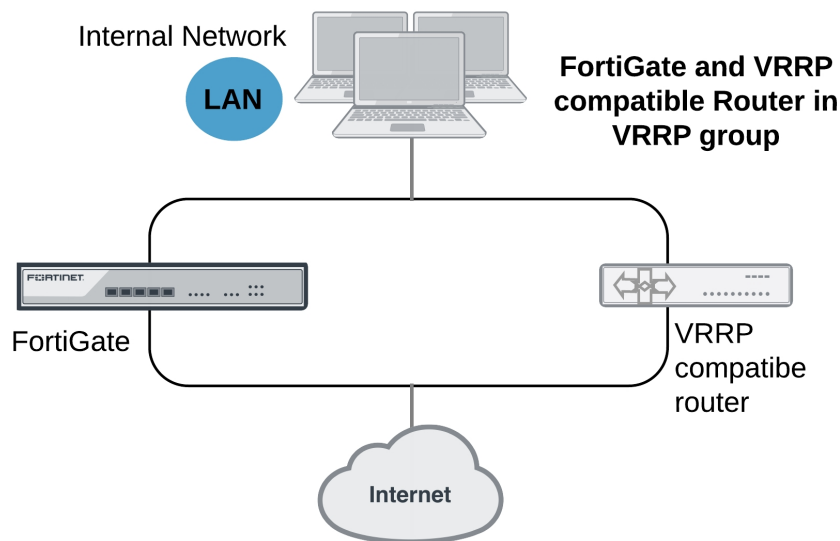

The FGSP also includes configuration synchronization, allowing you to make configuration changes once for both FortiGates instead of requiring duplicate configuration changes on each unit. However, settings that identify the FortiGate to the network, for example, interface IP addresses and BGP neighbor settings, are not synchronized so each FortiGate maintains its identity on the network. These settings must be configured separately for each FortiGate.

In previous versions of FortiOS the FGSP was called TCP session synchronization or standalone session synchronization. However, the FGSP has been expanded to include configuration synchronization and session synchronization of connectionless sessions, expectation sessions, and NAT sessions.

VRRP high availability

FortiGates can function as primary (master) or backup Virtual Router Redundancy Protocol (VRRP) routers and can be quickly and easily integrated into a network that has already deployed VRRP. A FortiGate can be integrated into a VRRP group with any third-party VRRP devices and VRRP can provide redundancy between multiple FortiGates. FortiOS supports VRRP version 2 and 3.

In a VRRP configuration, when a FortiGate operating as the primary router fails, a backup router takes its place and continues processing network traffic. If the backup router is a FortiGate, the network continues to benefit from FortiOS security features. If the backup router is simply a router, after a failure traffic will continue to flow, but FortiOS security features will be unavailable until the FortiGate is back on line. You can include different FortiGate models in the same VRRP group.

FortiOS supports IPv4 and IPv6 VRRP between two or more FortiGates and between FortiGates and third-party routers that support VRRP. Using VRRP, you can assign VRRP routers as primary or backup routers. The primary router processes traffic and the backup routers monitor the primary router and can begin forwarding traffic if the primary router fails. Similar to the FGCP, you can set up VRRP among multiple FortiGates to provide redundancy. You can also create a VRRP group with a FortiGate and any routers that support VRRP.

In a VRRP configuration that includes one FortiGate and one router, normally the FortiGate would be the primary router and all traffic would be processed by the FortiGate. If the FortiGate fails, all traffic switches to the router. Network connectivity is maintained even though FortiGate security features are unavailable until the FortiGate is back on line.

Session-Aware Load Balancing Clustering (SLBC)

Session-Aware Load Balancing Clusters consist of one or more FortiControllers acting as load balancers and two or more FortiGate-5000s and operating as workers all installed in one or two FortiGate-5000 series chassis.

SLBC clusters load balance TCP and UDP sessions. As a session-aware load balancer, the FortiController includes FortiASIC DP processors that maintain state information for all TCP and UDP sessions. The FortiASIC DP processors are capable of directing any TCP or UDP session to any worker installed in the same chassis. This session-awareness means that all TCP and UDP traffic being processed by a specific worker continues to be processed by the same worker. Session-awareness also means that more complex networking features such as network address translation (NAT), fragmented packets, complex UDP protocols, and complex protocols such as SIP that use pinholes, can be load balanced by the cluster.

For more information about SLBC see the *FortiController Session-Aware Load Balancing Guide*.

You cannot mix FGCP and SLBC clusters in the same FortiGate-5000 chassis.

Enhanced Load Balancing Clustering (ELBC)

ELBC uses FortiSwitch-5000 series load balancers to load balance traffic to FortiGate-5000 workers installed in a FortiGate-5000 chassis. ELBC enhances scalability, reliability, and availability of mission critical IP-based services, such as firewall, antivirus, web filtering, IPS, and so on. It also provides high availability by detecting worker failures and automatically redistributing traffic to the workers that are still operating.

ELBC applies a load balancing algorithm against the source and/or destination address of packets to generate a hash key value. Each worker has hash key values assigned to it. If the workers are running, then the traffic is forwarded to the worker assigned to the hash key. The hash key value generated by the algorithm, the hash keys accepted by the worker blades, and the blade the traffic is sent to are automatically calculated by the FortiSwitch.

For more information about ELBC see the *ELBC Configuration Guide*.

You cannot mix FGCP and ELBC clusters in the same FortiGate-5000 chassis.

Content clustering

A content cluster employs FortiSwitch-5203Bs or FortiController-5902Ds to load balance content sessions to FortiGate-5000 workers. FortiSwitch-5203B content clusters consist of one or more FortiSwitch-5203Bs and multiple FortiGate-5001Bs workers. FortiController-5902D content clusters consist of one or more FortiController-5902Ds and multiple FortiGate-5001B workers.

Operating as a FortiGate in content cluster mode, a primary FortiSwitch-5203B or FortiController-5902D performs routing, firewalling, stateful inspection, IPsec and SSL VPN encryption/decryption, and other FortiGate functions. The FortiSwitch-5203B includes NP4 processors and the FortiController-5902Ds includes NP6 processors and an integrated switch fabrics that provides fastpath acceleration by offloading communication sessions from the FortiGate CPU.

Using content cluster weighted load balancing, the FortiSwitch-5203Bs or FortiController-5902Ds distribute sessions that require content processing to the workers over the FortiGate-5000 chassis fabric backplane. Content processing sessions include proxy and flow-based security profile functions such as virus scanning, intrusion protection, application control, IPS, web filtering, email filtering, and VoIP. Load balancing is offloaded to the NP4 or NP6 processors resulting in improved load balancing performance. In some networks, the NP4 or NP6 processors also allow you to configure the efficiently load balance TCP and UDP sessions.

Content cluster mode is similar to active-active HA where the FortiSwitch-5203B or FortiController-5902D operates as the primary unit and load balances security profile sessions to the workers installed in the chassis using weighted load balancing. In this configuration, the HA mode is active-active, the HA load balancing schedule is weight-round-robin and load-balance-all is disabled. You can adjust the HA weighted load balancing weights to change how sessions are load balanced.

You can add a second FortiSwitch-5203B or FortiController-5902D to a content cluster as a backup. The primary FortiSwitch-5203B or FortiController-5902D can load balance sessions to the backup FortiSwitch-5203B or

FortiController-5902D as well as the workers. You can control how many sessions are processed by the backup FortiSwitch-5203B or FortiController-5902D by configuring the HA load balancing weights. You can also configure the content cluster to operate the backup FortiSwitch-5203B or FortiController-5902D in standby mode. In this mode the backup FortiSwitch-5203B or FortiController-5902D does not process any sessions but is just there to take over content clustering if the primary unit fails.

Once the content cluster has been established and all FortiControllers and workers have joined the cluster, you can configure the cluster from the FortiSwitch-5203B or FortiController-5902D GUI or CLI. All configuration changes made to the primary unit are automatically synchronized to all cluster units.

FortiSwitch-5203B or FortiController-5902D firmware upgrades are done from the primary FortiSwitch-5203B or FortiController-5902D GUI or CLI. Worker firmware upgrades are done from the FortiSwitch-5203B or FortiController-5902D CLI where a single firmware image is uploaded once and synchronized to all of the workers.

An introduction to the FGCP

A FortiGate HA cluster consists of two to four FortiGates configured for HA operation. Each FortiGate in a cluster is called a cluster unit. All cluster units must be the same FortiGate model with the same FortiOS firmware build installed. All cluster units must also have the same hardware configuration (for example, the same number of hard disks and so on) and be running in the same operating mode (NAT/Route mode or transparent mode).

You can create an FGCP cluster of up to four FortiGates.

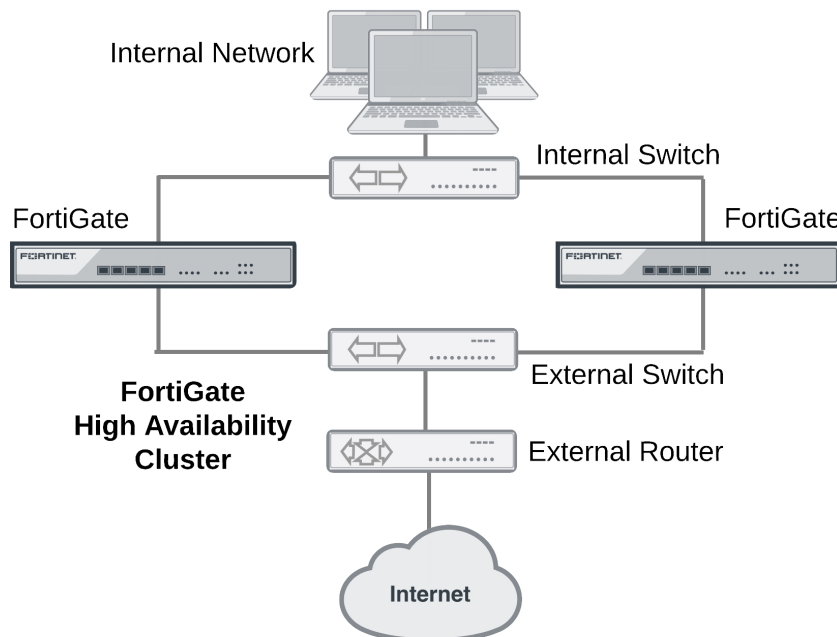

In addition the cluster units must be able to communicate with each other through their heartbeat interfaces. This heartbeat communication is required for the cluster to be created and to continue operating. Without it, the cluster acts like a collection of standalone FortiGates.

On startup, after configuring the cluster units with the same HA configuration and connecting their heartbeat interfaces, the cluster units use the FortiGate Clustering Protocol (FGCP) to find other FortiGates configured for HA operation and to negotiate to create a cluster. During cluster operation, the FGCP shares communication and synchronization information among the cluster units over the heartbeat interface link. This communication and synchronization is called the FGCP heartbeat or the HA heartbeat. Often, this is shortened to just heartbeat.

The cluster uses the FGCP to select the primary unit, and to provide device, link and session failover. The FGCP also manages the two HA modes; active-passive (failover HA) and active-active (load balancing HA).

About the FGCP

FortiGate HA is implemented by configuring two or more FortiGates to operate as an HA cluster. To the network, the HA cluster appears to function as a single FortiGate, processing network traffic and providing normal security services such as firewalling, security profile services, Security Fabric services, and VPN services.

HA cluster installed between an internal network and the internet

Inside the cluster the individual FortiGates are called cluster units. These cluster units share state and configuration information. If one cluster unit fails, the other units in the cluster automatically replace that unit, taking over the work that the failed unit was doing. After the failure, the cluster continues to process network traffic and provide normal FortiGate services with virtually no interruption.

Every FortiGate cluster contains one primary unit (also called the master unit) and one or more subordinate units (also called slave or backup units). The primary unit controls how the cluster operates. The role that the subordinate units play depends on the mode in which the cluster operates: (Active-Passive (AP) or Active-Active (AA).

The ability of an HA cluster to continue providing firewall services after a failure is called failover. FGCP failover means that your network does not have to rely on one FortiGate to continue functioning. You can install additional units and form an HA cluster.

A second HA feature, called active-active load balancing, can be used to increase performance. An active-active cluster of FortiGates can increase overall network performance by sharing the load of processing network traffic and providing security services. The cluster appears to your network to be a single device, adding increased performance without changing your network configuration.

Virtual clustering extends HA features to provide failover protection and load balancing for Virtual Domains (VDOMs). See [Virtual clusters on page 1463](#).

FortiGate models that support redundant interfaces can be configured to support full mesh HA. Full mesh HA is a method of reducing the number of single points of failure on a network that includes an HA cluster. For details about full mesh HA, see [Full mesh HA on page 1473](#).

FGCP failover protection

The FGCP provides IP/MAC takeover failover protection by assigning virtual MAC addresses to the primary cluster unit and then sending gratuitous ARP packets from the primary unit interfaces to reprogram the network.

Failover times can be less than a second under optimal conditions. You can fine tune failover performance for your network by adjusting cluster status checking timers, routing table update timers, and wait timers.

An HA cluster fails over if the primary unit fails (a device failure) or experiences a link failure. The cluster can detect link failures for connections to the primary unit using port monitoring and for connections between downstream network components using remote IP monitoring. To compensate for a link failover, the cluster maintains active links to keep traffic flowing between high-priority networks. Port and remote IP monitoring can be fine tuned without disrupting cluster operation.

Session failover

FGCP session failover maintains TCP, SIP and IPsec VPN sessions after a failure. You can also configure session failover to maintain UDP and ICMP sessions. Session failover does not failover SSL VPN sessions. Session failover may not be required for all networks because many TCP/IP, UDP, and ICMP protocols can resume sessions on their own. Supporting session failover adds extra overhead to cluster operations and can be disabled to improve cluster performance if it is not required.

Load balancing

Active-active HA load balances resource-intensive security profile features such as virus scanning, web filtering, intrusion protection, application control, email filtering and data leak prevention operations among all cluster units to provide better performance than a standalone FortiGate. If network traffic consists of mainly TCP sessions, the FGCP can also load balance all TCP sessions to improve TCP performance in some network configurations. On some FortiGate models you can also load balance UDP sessions. NP4 and NP6 offloading can accelerate HA load balancing (especially TCP and UDP load balancing). HA load balancing schedules can be adjusted to optimize performance for the traffic mix on your network. Weighted load balancing can be used to control the relative amount of sessions processed by each cluster unit.

Virtual clustering

Virtual clustering is an extension of the FGCP for a cluster of 2 FortiGates operating with multiple VDOMS enabled. Not only does virtual clustering provide failover protection for a multiple VDOM configuration, but a virtual cluster can load balance traffic between the cluster units. Load balancing with virtual clustering is quite efficient and load balances all traffic. It is possible to fine tune virtual clustering load balancing in real time to actively optimize load sharing between the cluster units without affecting the smooth operation of the cluster.

Full mesh HA

High availability improves the reliability of a network by replacing a single point of failure (a single FortiGate) with a cluster that can maintain network traffic if one of the cluster units fails. However, in a normal FGCP cluster, single points of failure remain. Full mesh HA removes these single points of failure by allowing you to connect redundant switches to each cluster interface. Full mesh HA is achieved by configuring 802.3ad aggregate or redundant interfaces on the FortiGate and connecting redundant switches to these interfaces. Configuration is a relatively simple extension of the normal aggregate interface and HA configurations.

Cluster management

FortiOS HA provides a wide range of cluster management features:

- Automatic continuous configuration synchronization. You can get a cluster up and running almost as quickly as a standalone FortiGate by performing a few basic steps to configure HA settings and minimal network settings on each cluster unit. When the cluster is operating you can configure FortiGate features such as firewalling, content inspection, and VPN in the same way as for a standalone FortiGate. All configuration changes (even complex changes such as switching to multiple VDOM mode or from NAT/Route to transparent mode) are synchronized among all cluster units.
- Firmware upgrades/downgrades. Upgrading or downgrading cluster firmware is similar to upgrading or downgrading standalone FortiGate firmware. The Firmware is uploaded once to the primary unit and the cluster automatically upgrades or downgrades all cluster units in one operation with minimal or no service interruption.
- Individual cluster unit management. In some cases you may want to manage individual cluster units. You can do so from cluster CLI by navigating to each cluster unit. You can also use the reserved management interface feature to give each cluster unit its own IP address and default route. You can use the reserved management interfaces and IP addresses to connect to the GUI and CLI of each cluster unit and configure an SNMP server to poll each cluster unit.
- Removing and adding cluster units. In one simple step any unit (even the primary unit) can be removed from a cluster and given a new IP address. The cluster keeps operating as it was; the transition happening without interrupting cluster operation. A new unit can also be added to an operating cluster without disrupting network traffic. All you have to do is connect the new unit and change its HA configuration to match the cluster's. The cluster automatically finds and adds the unit and synchronizes its configuration with the cluster.
- Debug and diagnose commands. An extensive range of debug and diagnose commands can be used to report on HA operation and find and fix problems.
- Logging and reporting. All cluster units can be configured to record all log messages. These message can be stored on the individual cluster units or sent to a FortiAnalyzer unit. You can view all cluster unit log messages by logging into any cluster unit.
- FortiManager support. FortiManager understands FortiOS HA and automatically recognizes when you add a FortiOS cluster to the FortiManager configuration.

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit. This means that in most cases you only have to make a configuration change once to have it synchronized to all cluster units.

Synchronizing the configuration (and settings that are not synchronized)

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit. This means that in most cases you only have to make a configuration change once to have it synchronized to all cluster units. This includes special configuration settings that include extra information (for example, 3rd party certificates, replacement message text files and graphics and so on).

Some configuration settings are not synchronized to support some aspects of FortiGate operation. The following settings are not synchronized among cluster units:

- The FortiGate host name. Allows you to identify cluster units.
- The GUI Dashboard configuration. After a failover you may have to re-configure dashboard widgets.
- HA override.
- HA device priority.
- Virtual cluster 1 and Virtual cluster 2 device priorities.
- The HA priority (`ha-priority`) setting for a ping server or dead gateway detection configuration.
- The system interface settings of the FortiGate interface that becomes the HA reserved management interface.

- The default route for the reserved management interface, set using the `ha-mgmt-interface-gateway` option of the `config system ha` command.
- The dynamic weighted load balancing thresholds and high and low watermarks.
- OSPF `summary-addresses` settings.

In addition licenses are not synchronized since each FortiGate must be licensed separately. This includes FortiCloud activation and FortiClient licensing, and entering a license key if you purchased more than 10 Virtual Domains (VDOMS).

Preparing the FortiGates before setting up an FGCP cluster

Before creating an FGCP cluster you should complete the following setup on each FortiGate.

DHCP and PPPoE

Make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP or PPPoE you should temporarily switch it to a static address and enable DHCP or PPPoE after the cluster has been established.

Firmware version

Make sure the FortiGates are running the same FortiOS firmware version.

About HA and licensing

All of the FortiGates in a cluster must have the same level of licensing. This includes licensing for FortiCare Support, IPS, AntiVirus, Web Filtering, Mobile Malware, FortiClient, FortiCloud, and additional virtual domains (VDOMS).

If one of the FortiGates in a cluster has a lower level of licensing than other FortiGates in the cluster, then all of the FortiGates in the cluster will revert to that lower licensing level. For example, if you only purchase FortiGuard Web Filtering for one of the FortiGates in a cluster, when the cluster is operating, none of the cluster units will support FortiGuard Web Filtering.

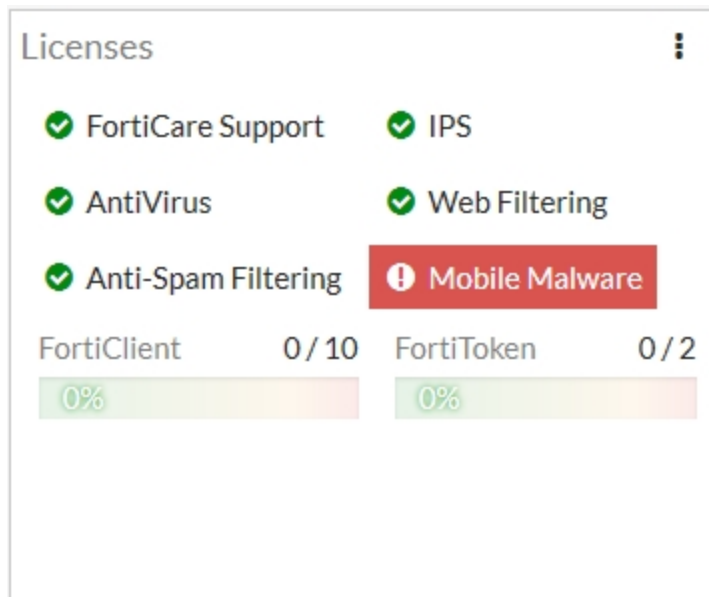

An exception is FortiToken licensing. FortiToken activations are completed one FortiGate unit and synchronized to all of the FortiGates in the cluster.

FortiOS Carrier license

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license. All FortiGates in the cluster must be licensed for FortiOS Carrier.

Support contracts and FortiGuard, FortiCloud, FortiClient, and VDOM licensing

Register and apply these licenses to each FortiGate. This includes FortiCloud activation and FortiClient licensing, and entering a license key if you purchased more than 10 Virtual Domains (VDOMS). All FortiGates in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient and VDOMs.

FortiToken licenses

You only need one set of FortiToken licenses for the HA cluster and you only need to activate each token once. Normally you would activate your tokens on the primary unit and this configuration and the seed information will be synchronized to all cluster members so all tokens will then be activated for all cluster members.

If you have added FortiToken licenses and activated FortiTokens on a standalone FortiGate unit before configuring HA, the licenses and the FortiToken activations will usually be synchronized to all cluster units after forming a cluster. To make sure this goes smoothly you can make sure the FortiGate that you have added the licenses to becomes the primary unit when setting up the cluster as described in [How to set up FGCP clustering \(recommended steps\)](#) on page 1412.

Certificates

You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.

Configuring FortiGates for FGCP HA operation

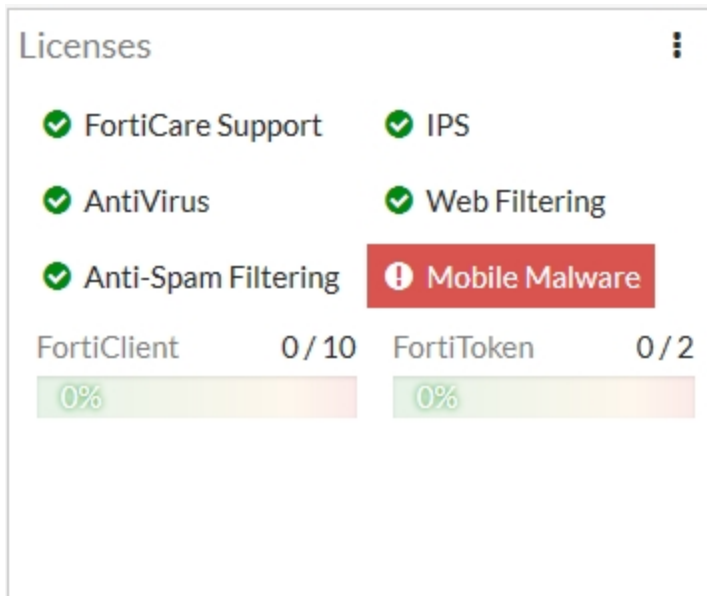

Each FortiGate in the cluster must have the same HA configuration. Once the cluster is connected, you can configure it in the same way as you would configure a standalone FortiGate. The following example sets the HA mode to active-passive and the HA password to HA_pass.

Make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP or PPPoE you should temporarily switch it to a static address and enable DHCP or PPPoE after the cluster has been established.

Make sure both FortiGates are running the same FortiOS firmware version. Register and apply licenses to both FortiGates before adding them to the cluster. This includes licensing for FortiCare Support, IPS, AntiVirus, Web Filtering, Mobile Malware, FortiClient, FortiCloud, and additional virtual domains (VDOMs). All FortiGates in the

cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs. FortiToken licenses can be added at any time because they are synchronized to all cluster members.

You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed, third-party certificates are synchronized to the backup FortiGate.

To configure a FortiGate for HA operation - GUI

1. Power on the FortiGate to be configured.
2. Log into the GUI.
3. Locate the System Information Dashboard widget. Click on the System Information dashboard widget and select **Configure settings in System > Settings**.
4. Enter a new Host Name for this FortiGate.
Changing the host name makes it easier to identify individual cluster units when the cluster is operating.
5. Go to **System > HA** and change the following settings:

Mode	Active-Passive
Group Name	Example_cluster
Password	HA_pass
The password must be the same for all FortiGates in the cluster.	

You can accept the default configuration for the remaining HA options and change them later, once the cluster is operating.

6. Select **OK**.
The FortiGate negotiates to establish an HA cluster. When you select **OK** you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all ARP table entries). You may be able to delete the ARP table

of your management PC from a command prompt using a command similar to `arp -d`.

7. Power off the FortiGate.
8. Repeat this procedure for all of the FortiGates in the cluster.
Once all of the units are configured, continue by connecting the FortiGate HA cluster below.

To configure a FortiGate for HA operation - CLI

1. Power on the FortiGate to be configured.
2. Log into the CLI.
3. Enter the following command to change the FortiGate host name.

```
config system global
  set hostname Example1_host
end
```

Changing the host name makes it easier to identify individual cluster units when the cluster is operating.

4. Enter the following command to enable HA:

```
config system ha
  set mode active-passive
  set group-name Example_cluster
  set password HA_pass
end
```

You can accept the default configuration for the remaining HA options and change them later, once the cluster is operating.

The FortiGate negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate interfaces. To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

5. Power off the FortiGate.
6. Repeat this procedure for all of the FortiGates in the cluster.
Once all of the units are configured, continue with connecting the FortiGate HA cluster.

Connecting a FortiGate HA cluster

Use the following procedure to connect a cluster. Connect the cluster units to each other and to your network. You must connect all matching interfaces in the cluster to the same switch, then connect these interfaces to their networks using the same switch.

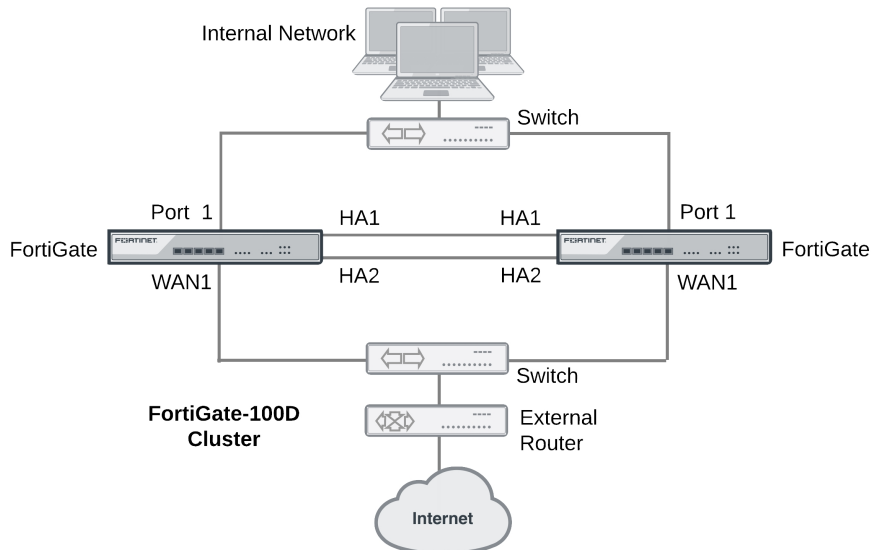

Although you can use hubs, Fortinet recommends using switches for all cluster connections for the best performance.

Connecting an HA cluster to your network temporarily interrupts communications on the network because new physical connections are being made to route traffic through the cluster. Also, starting the cluster interrupts network traffic until the individual cluster units are functioning and the cluster completes negotiation. Cluster negotiation is automatic and normally takes just a few seconds. During system startup and negotiation all network traffic is dropped.

This section describes how to connect the cluster shown below, which consists of two FortiGate-100D units to be connected between the internet and a head office internal network. The wan1 interfaces of the FortiGate connect

the cluster to the internet and the internal interfaces connect the cluster to the internal network. The ha1 and ha2 interfaces are used for redundant HA heartbeat links.

Example cluster connections

To connect a FortiGate HA cluster

1. Connect the WAN1 interfaces of each cluster unit to a switch connected to the internet.
2. Connect the Port1 interfaces of each cluster unit to a switch connected to the internal network.
3. Connect the HA1 interfaces of the cluster units together. You can use a crossover Ethernet cable or a regular Ethernet cable. (You can also connect the interfaces using Ethernet cables and a switch.)
4. Connect the HA2 interfaces of the cluster units together. You can use a crossover Ethernet cable or a regular Ethernet cable. (You can also connect the interfaces using Ethernet cables and a switch.)
5. Power on both of the FortiGates.

As the cluster units start, they negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally just takes a few seconds.

At least one heartbeat interface should be connected together for the cluster to operate.

Do not use a switch port for the HA heartbeat traffic. This configuration is not supported.

You could use one switch to connect all four heartbeat interfaces. However, this is not recommended because if the switch fails both heartbeat interfaces will become disconnected.

6. You can now configure the cluster as if it is a single FortiGate.

Verifying the cluster status from the HA Status dashboard widget

The HA Status dashboard widget shows the mode and group names of the cluster, the status of the cluster units and their host names, the cluster uptime and the last time the cluster state changed. A state change can indicate the cluster first forming or one of the cluster units changing its role in the cluster.

The HA Status Dashboard widget also shows if the cluster units are synchronized. Mouse over each FortiGate in the cluster to verify that they both have the same checksum.

From the HA Status widget you can also select **Show HA Historical Events** to see the most recent HA system status messages.

HA Historical Events		
#	Date/Time	Event
1	10-05 14:41	FGT6HD3916800525 is elected as the cluster master of 2 members
2	10-05 14:41	new member 'FGT6HD3916801195' joins the cluster
3	10-05 14:41	hbdev port4 link status changed: 0->1
4	10-05 14:41	port port4 link status changed: 0->1
5	10-05 14:41	hbdev port4 link status changed: 1->0
6	10-05 14:41	port port4 link status changed: 1->0
7	10-05 14:41	hbdev port4 link status changed: 0->1
8	10-05 14:41	hbdev port3 link status changed: 0->1
9	10-05 14:41	port port4 link status changed: 0->1
10	10-05 14:41	port port3 link status changed: 0->1
11	10-05 14:40	hbdev port4 link status changed: 1->0
12	10-05 14:40	hbdev port3 link status changed: 1->0
13	10-05 14:40	port port4 link status changed: 1->0

Active-passive and active-active HA

The first decision to make when configuring FortiGate HA is whether to choose active-passive or active-active HA mode. To configure the HA mode, go to **System > HA** and set Mode to **Active-Passive** or **Active-Active**.

From the CLI enter the following command to set the HA mode to active-passive:

```
config system ha
  set mode a-p
end
```

To form a cluster, all cluster units must be set to the same mode. You can also change the mode after the cluster is up and running. Changing the mode of a functioning cluster causes a slight delay while the cluster renegotiates to operate in the new mode and possibly select a new primary unit.

Active-passive HA (failover protection)

An active-passive (A-P) HA cluster provides hot standby failover protection. An active-passive cluster consists of a primary unit that processes communication sessions, and one or more subordinate units. The subordinate units are connected to the network and to the primary unit but do not process communication sessions. Instead, the subordinate units run in a standby state. In this standby state, the configuration of the subordinate units is synchronized with the configuration of the primary unit and the subordinate units monitor the status of the primary unit.

Active-passive HA provides transparent device failover among cluster units. If a cluster unit fails, another immediately take its place.

Active-passive HA also provides transparent link failover among cluster units. If a cluster unit interface fails or is disconnected, this cluster unit updates the link state database and the cluster negotiates and may select a new primary unit.

If session failover (also called session pickup) is enabled, active-passive HA provides session failover for some communication sessions.

The following example shows how to configure a FortiGate for active-passive HA operation. You would enter the exact same commands on every FortiGate in the cluster.

```
config system ha
  set mode a-p
  set group-name myname
  set password HApass
end
```

Active-active HA (load balancing and failover protection)

By default, active-active HA load balancing distributes proxy-based security profile processing to all cluster units. Proxy-based security profile processing is CPU and memory-intensive, so FGCP load balancing may result in higher throughput because resource-intensive processing is distributed among all cluster units.

Normally, sessions accepted by policies that don't include security profiles are not load balanced and are processed by the primary unit. You can configure active-active HA to load balance additional sessions.

An active-active HA cluster consists of a primary unit that receives all communication sessions and load balances them among the primary unit and all of the subordinate units. In an active-active cluster the subordinate units are also considered active since they also process content processing sessions. In all other ways active-active HA operates the same as active-passive HA.

The following example shows how to configure a FortiGate for active-active HA operation. You would enter the exact same commands on every FortiGate in the cluster.

```
config system ha
  set mode a-a
  set group-name myname
  set password HApass
end
```

Identifying the cluster and cluster units

You can use the cluster group name, group id, and password to identify a cluster and distinguish one cluster from another. If you have more than one cluster on the same network, each cluster must have a different group name, group id, and password.

Group name

Use the group name to identify the cluster. The maximum length of the group name is 32 characters. The group name must be the same for all cluster units before the cluster units can form a cluster. After a cluster is operating, you can change the group name. The group name change is synchronized to all cluster units. The group name appears on the HA Status dashboard widget.

To add or change the group name from the GUI go to **System > HA** and change the **Group name**.

Enter the following CLI command to change the group name to Cluster_name:

```
config system ha
    set group-name Cluster_name
end
```

Password

Use the password to identify the cluster. You should always change the password when configuring a cluster. The password must be the same for all FortiGates before they can form a cluster. When the cluster is operating you can change the password, if required. Two clusters on the same network cannot have the same password.

To change the password from the GUI go to **System > HA** and change the **Password**.

Enter the following CLI command to change the password to ha_pwd:

```
config system ha
    set password ha_pwd
end
```

Group ID

Similar to the group name, the group ID is also identifies the cluster. In most cases you do not have to change the group ID. However, you should change the group ID if you have more than one cluster on the same network. All members of the HA cluster must have the same group ID. The group ID is a number from 0 to 255.

Changing the group ID changes the cluster virtual MAC address. If two clusters on the same network have the same group ID you may encounter MAC address conflicts.

Enter the following CLI command to change the group ID to 10:

```
config system ha
    set group-id 10
end
```

Device failover, link failover, and session failover

The FGCP provides transparent device and link failover. You can also enable session pickup to provide session failover. A failover can be caused by a hardware failure, a software failure, or something as simple as a network cable being disconnected causing a link failover. When a failover occurs, the cluster detects and recognizes the failure and takes steps to respond so that the network can continue to operate without interruption. The internal operation of the cluster changes, but network components outside of the cluster notice little or no change.

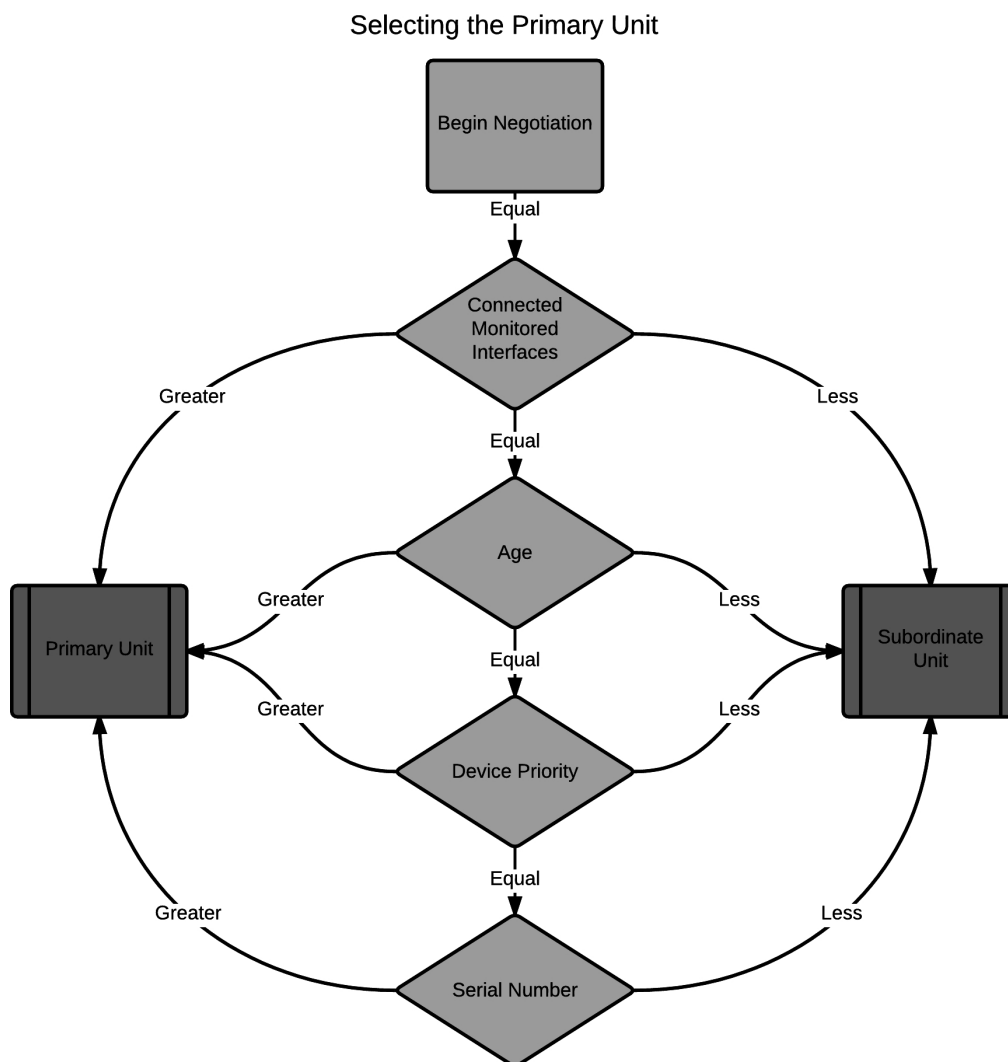

If a failover occurs, the cluster also records log messages about the event and can be configured to send log messages to a syslog server and to a FortiAnalyzer unit. The cluster can also send SNMP traps and alert email messages. These alerts can notify network administrators of the failover and may contain information that the network administrators can use to find and fix the problem that caused the failure.

For a complete description of device failover, link failover, and session failover, how clusters support these types of failover, and how FortiGate HA clusters compensate for a failure to maintain network traffic flow see [HA and failover protection on page 1521](#).

Primary unit selection

Once FortiGates recognize that they can form a cluster, the cluster units negotiate to select a primary unit. Primary unit selection occurs automatically based on the criteria shown below. After the cluster selects the primary unit, all of the remaining cluster units become subordinate units.

Negotiation and primary unit selection also takes place if a primary unit fails (device failover) or if a monitored interface fails or is disconnected (link failover). During a device or link failover, the cluster renegotiates to select a new primary unit also using the criteria shown below.

For many basic HA configurations primary unit selection simply selects the cluster unit with the highest serial number to become the primary unit. A basic HA configuration involves setting the HA mode to active-passive or

active-active and configuring the cluster group name and password. Using this configuration, the cluster unit with the highest serial number becomes the primary unit because primary unit selection disregards connected monitored interfaces (because interface monitoring is not configured), the age of the cluster units would usually always be the same, and all units would have the same device priority.

Using the serial number is a convenient way to differentiate cluster units; so basing primary unit selection on the serial number is predictable and easy to understand and interpret. Also the cluster unit with the highest serial number would usually be the newest FortiGate with the most recent hardware version. In many cases you may not need active control over primary unit selection, so basic primary unit selection based on serial number is sufficient.

In some situations you may want have control over which cluster unit becomes the primary unit. You can control primary unit selection by setting the device priority of one cluster unit to be higher than the device priority of all other cluster units. If you change one or more device priorities, during negotiation, the cluster unit with the highest device priority becomes the primary unit. As shown above, the FGCP selects the primary unit based on device priority before serial number. For more information about how to use device priorities, see [Primary unit selection and device priority on page 1390](#).

The only other way that you can influence primary unit selection is by configuring interface monitoring (also called port monitoring). Using interface monitoring you can make sure that cluster units with failed or disconnected monitored interfaces cannot become the primary unit. See [Primary unit selection and monitored interfaces on page 1387](#).

Finally, the age of a cluster unit is determined by a number of operating factors. Normally the age of all cluster units is the same so normally age has no effect on primary unit selection. Age does affect primary unit selection after a monitored interface failure. For more information about age, see [Primary unit selection and age on page 1387](#).

Viewing how the primary unit was selected

You can use the `get system ha status` command to see how the primary unit was selected. The output of this command contains a section called `Master selected using` that shows a history of how the primary unit was selected. For example, when a cluster first forms this part of the command output could have one line showing that the primary unit is the cluster unit with the highest uptime.

```
get system ha status
.
.
.
Master selected using:
    <2016/10/12 11:13:23> FG-5KD3914800344 is selected as the master because it
has the largest value of uptime.
.
.
.
```

Over time more messages could be added as the cluster negotiates to choose a new primary unit on different occasions. The command output below shows the cluster negotiated four times over a few days.

```
get system ha status
.
.
.
Master selected using:
```

```
<2016/10/16 11:36:07> FG-5KD3914800344 is selected as the master because it
has the largest value of uptime.
<2016/10/15 11:24:11> FG-5KD3914800284 is selected as the master because it
has the largest value of override priority.
<2016/10/13 11:15:13> FG-5KD3914800344 is selected as the master because it
has the largest value of uptime.
<2016/10/11 11:13:23> FG-5KD3914800344 is selected as the master because it
has the largest value of uptime.
.
.
.
```

Primary unit selection and monitored interfaces

If you have configured interface monitoring the cluster unit with the highest number of monitored interfaces that are connected to networks becomes the primary unit. Put another way, the cluster unit with the highest number of failed or disconnected monitored interfaces cannot become the primary unit.

Normally, when a cluster starts up, all monitored interfaces of all cluster units are connected and functioning normally. So monitored interfaces do not usually affect primary unit selection when the cluster first starts.

A cluster always renegotiates when a monitored interface fails or is disconnected (called link failover). A cluster also always renegotiates when a failed or disconnected monitored interface is restored.

If a primary unit monitored interface fails or is disconnected, the cluster renegotiates and if this is the only failed or disconnected monitored interface the cluster selects a new primary unit.

If a subordinate unit monitored interface fails or is disconnected, the cluster also renegotiates but will not necessarily select a new primary unit. However, the subordinate unit with the failed or disconnected monitored interface cannot become the primary unit.

Multiple monitored interfaces can fail or become disconnected on more than one cluster unit. Each time a monitored interface is disconnected or fails, the cluster negotiates to select the cluster unit with the most connected and operating monitored interfaces to become the primary unit. In fact, the intent of the link failover feature is just this, to make sure that the primary unit is always the cluster unit with the most connected and operating monitored interfaces.

Primary unit selection and age

The cluster unit with the highest age value becomes the primary unit. The age of a cluster unit is the amount of time since a monitored interface failed or is disconnected. Age is also reset when a cluster unit starts (boots up). So, when all cluster units start up at about the same time, they all have the same age. Age does not affect primary unit selection when all cluster units start up at the same time. Age also takes precedence over priority for primary unit selection.

If a link failure of a monitored interface occurs, the age value for the cluster unit that experiences the link failure is reset. So, the cluster unit that experienced the link failure also has a lower age value than the other cluster units. This reduced age does not effect primary unit selection because the number of link failures takes precedence over the age.

If the failed monitored interface is restored the cluster unit that had the failed monitored interface cannot become the primary unit because its age is still lower than the age of the other cluster units.

In most cases, the way that age is handled by the cluster reduces the number of times the cluster selects a new primary unit, which results in a more stable cluster since selecting a new primary unit has the potential to disrupt traffic.

Cluster age difference margin (grace period)

In any cluster, some of the cluster units may take longer to start up than others. This startup time difference can happen as a result of a number of issues and does not affect the normal operation of the cluster. To make sure that cluster units that start slower can still become primary units, by default the FGCP ignores age differences of up to 5 minutes (300 seconds).

In most cases, during normal operation this age difference margin or grace period helps clusters function as expected. However, the age difference margin can result in some unexpected behavior in some cases:

- During a cluster firmware upgrade with `uninterruptible-upgrade` enabled (the default configuration) the cluster should not select a new primary unit after the firmware of all cluster units has been updated. But since the age difference of the cluster units is most likely less than 300 seconds, age is not used to affect primary unit selection and the cluster may select a new primary unit.
- During failover testing where cluster units are failed over repeatedly the age difference between the cluster units will most likely be less than 5 minutes. During normal operation, if a failover occurs, when the failed unit rejoins the cluster its age will be very different from the age of the still operating cluster units so the cluster will not select a new primary unit. However, if a unit fails and is restored in a very short time the age difference may be less than 5 minutes. As a result the cluster may select a new primary unit during some failover testing scenarios.

Changing the cluster age difference margin

You can change the cluster age difference margin using the following command:

```
config system ha
    set ha-uptime-diff-margin 60
end
```

This command sets the cluster age difference margin to 60 seconds (1 minute). The age difference margin range is 1 to 65535 seconds. The default is 300 seconds.

You may want to reduce the margin if during failover testing you don't want to wait the default age difference margin of 5 minutes. You may also want to reduce the margin to allow uninterruptible upgrades to work. See [Operating clusters and virtual clusters on page 1487](#).

You may want to increase the age margin if cluster unit startup time differences are larger than 5 minutes.

Displaying cluster unit age differences

You can use the CLI command `diagnose sys ha dump-by group` to display the age difference of the units in a cluster. This command also displays information about a number of HA-related parameters for each cluster unit.

For example, consider a cluster of two FortiGate units. Entering the `diagnose sys ha dump-by group` command from the primary unit CLI displays information similar to the following:

```
diagnose sys ha dump-by group
    HA information.
group-id=0, group-name='External-HA-Cluster'

gmember_nr=2
'FGT6HD3916800525': ha_ip_idx=1, hb_packet_version=6, last_hb_jiffies=52097155,
```

```

linkfails=11, weight/o=0/0
    hbdev_nr=2: port3(mac=906c..70, last_hb_jiffies=52097155, hb_lost=0), port4(mac-
c=906c..71, last_hb_jiffies=52097155, hb_lost=0),
'FGT6HD3916801195': ha_ip_idx=0, hb_packet_version=6, last_hb_jiffies=0, link-
fails=0, weight/o=0/0

vcluster_nr=1
vcluster_0: start_time=1507754642(2017-10-11 13:44:02), state/o/chg_time=2(work)/2
(work)/1507754644(2017-10-11 13:44:04)
    'FGT6HD3916801955': ha_prio/o=1/1, link_failure=0(old=0), pingsvr_failure=0, flag-
g=0x00000000, uptime/reset_cnt=0/1
    'FGT6HD3916800525': ha_prio/o=0/0, link_failure=0(old=0), pingsvr_failure=0, flag-
g=0x00000001, uptime/reset_cnt=189/0

```

The last two lines of the output display status information about each cluster unit including the `uptime`. The `uptime` is the age difference in seconds/10 between the two units in the cluster.

In the example, the age of the subordinate unit 189 or is 18.9 seconds more than the age of the primary unit. The age difference is less than 5 minutes (less than 300 seconds) so age has no affect on primary unit selection. The cluster selected the unit with the highest serial number to be the primary unit.

If port1 (the monitored interface) of the primary unit is disconnected, the cluster renegotiates and the former subordinate unit becomes the primary unit. When you log into the new primary unit CLI and enter `diagnose sys ha dump-by group` you could get results similar to the following:

```

diagnose sys ha dump-by group
    HA information.
group-id=0, group-name='External-HA-Cluster'

gmember_nr=2
'FGT6HD3916800525': ha_ip_idx=1, hb_packet_version=6, last_hb_jiffies=52097155,
linkfails=11, weight/o=0/0
    hbdev_nr=2: port3(mac=906c..70, last_hb_jiffies=52097155, hb_lost=0), port4(mac-
c=906c..71, last_hb_jiffies=52097155, hb_lost=0),
'FGT6HD3916801195': ha_ip_idx=0, hb_packet_version=6, last_hb_jiffies=0, link-
fails=0, weight/o=0/0

vcluster_nr=1
vcluster_0: start_time=1507754642(2017-10-11 13:44:02), state/o/chg_time=2(work)/2
(work)/1507754644(2017-10-11 13:44:04)
    'FGT6HD3916800525': ha_prio/o=1/1, link_failure=0(old=0), pingsvr_failure=0, flag-
g=0x00000000, uptime/reset_cnt=0/1
    'FGT6HD3916801955': ha_prio/o=0/0, link_failure=0(old=0), pingsvr_failure=0, flag-
g=0x00000001, uptime/reset_cnt=1362/0

```

The command results show that the age of the new primary unit is 136.2 seconds higher than the age of the new subordinate unit.

If port1 of the former primary unit is reconnected the cluster will once again make this the primary unit because the age difference will still be less than 300 seconds. When you log into the primary unit CLI and enter `diagnose sys ha dump-by group` you get results similar to the following:

```

diagnose sys ha dump-by group
    HA information.
group-id=0, group-name='External-HA-Cluster'

```

```

gmember_nr=2
'FGT6HD3916800525': ha_ip_idx=1, hb_packet_version=6, last_hb_jiffies=52097155,
linkfails=11, weight/o=0/0
    hbdev_nr=2: port3(mac=906c..70, last_hb_jiffies=52097155, hb_lost=0), port4(mac-
c=906c..71, last_hb_jiffies=52097155, hb_lost=0),
'FGT6HD3916801195': ha_ip_idx=0, hb_packet_version=6, last_hb_jiffies=0, link-
fails=0, weight/o=0/0

vcluster_nr=1
vcluster_0: start_time=1507754642(2017-10-11 13:44:02), state/o/chg_time=2(work)/2
(work)/1507754644(2017-10-11 13:44:04)
    'FGT6HD3916800525': ha_prio/o=1/1, link_failure=0(old=0), pingsvr_failure=0, flag-
g=0x00000000, uptime/reset_cnt=0/1
    'FGT6HD3916801955': ha_prio/o=0/0, link_failure=0(old=0), pingsvr_failure=0, flag-
g=0x00000001, uptime/reset_cnt=-1362/0

```

Resetting the age of all cluster units

In some cases, age differences among cluster units can result in the wrong cluster unit or the wrong virtual cluster becoming the primary unit. For example, if a cluster unit set to a high priority reboots, that unit will have a lower age than other cluster units when it rejoins the cluster. Since age takes precedence over priority, the priority of this cluster unit will not be a factor in primary unit selection.

This problem also affects virtual cluster VDOM partitioning in a similar way. After a reboot of one of the units in a virtual cluster configuration, traffic for all VDOMs could continue to be processed by the cluster unit that did not reboot. This can happen because the age of both virtual clusters on the unit that did not reboot is greater than the age of both virtual clusters on the unit that rebooted.

One way to resolve this issue is to reboot all of the cluster units at the same time so that the age of all of the cluster units is reset. However, rebooting cluster units may interrupt or at least slow down traffic. If you would rather not reboot all of the cluster units you can instead use the following command to reset the age of individual cluster units.

```
diagnose sys ha reset-uptime
```

This command resets the age of a unit back to zero so that if no other unit in the cluster was reset at the same time, it will now have the lowest age. You would use this command to reset the age of the cluster unit that is currently the primary unit. Since it will have the lowest age, the other unit in the cluster will have the highest age and can then become the primary unit.

The `diagnose sys ha reset-uptime` command should only be used as a temporary solution. The command resets the HA age internally and does not affect the up time displayed for cluster units using the `diagnose sys ha dump-by all-vcluster` command or the up time displayed on the Dashboard or cluster members list. To make sure the actual up time for cluster units is the same as the HA age you should reboot the cluster units during a maintenance window.

Primary unit selection and device priority

A cluster unit with the highest device priority becomes the primary unit when the cluster starts up or renegotiates. By default, the device priority for all cluster units is 128. You can change the device priority to control which FortiGate becomes the primary unit during cluster negotiation. All other factors that influence primary unit selection either cannot be configured (age and serial number) or are synchronized among all cluster units.

(interface monitoring). You can set a different device priority for each cluster unit. During negotiation, if all monitored interfaces are connected, and all cluster units enter the cluster at the same time (or have the same age), the cluster with the highest device priority becomes the primary unit.

A higher device priority does not affect primary unit selection for a cluster unit with the most failed monitored interfaces or with an age that is higher than all other cluster units because failed monitored interfaces and age are used to select a primary unit before device priority.

Increasing the device priority of a cluster unit does not always guarantee that this cluster unit will become the primary unit. During cluster operation, an event that may affect primary unit selection may not always result in the cluster renegotiating. For example, when a unit joins a functioning cluster, the cluster will not renegotiate. So if a unit with a higher device priority joins a cluster the new unit becomes a subordinate unit until the cluster renegotiates.

Enabling the `override` HA CLI keyword makes changes in device priority more effective by causing the cluster to negotiate more often to make sure that the primary unit is always the unit with the highest device priority. For more information about `override`, see [Primary unit selection on page 1385](#).

Controlling primary unit selection by changing the device priority

You set a different device priority for each cluster unit to control the order in which cluster units become the primary unit when the primary unit fails.

To change the device priority from the GUI go to **System > HA** and change the **Device priority**.

Enter the following CLI command to change the device priority to 200:

```
config system ha
  set priority 200
end
```

The device priority is not synchronized among cluster units. In a functioning cluster you can change the device priority of any unit in the cluster. Whenever you change the device priority of a cluster unit, when the cluster negotiates, the unit with the highest device priority becomes the primary unit.

The following example shows how to change the device priority of a subordinate unit to 255 so that this subordinate unit becomes the primary unit. You can change the device priority of a subordinate unit by going to **System > HA** and selecting the Edit icon for the subordinate unit. Or from the CLI you can use the `execute ha manage 0` command to connect to the highest priority subordinate unit. After you enter the following commands the cluster renegotiates and selects a new primary unit.

```
execute ha manage 1
config system ha
  set priority 255
end
```

If you have three units in a cluster you can set the device priorities as shown below. When the cluster starts up, cluster unit A becomes the primary unit because it has the highest device priority. If unit A fails, unit B becomes the primary unit because unit B has a higher device priority than unit C.

Example device priorities for a cluster of three FortiGates

Cluster unit	Device priority
A	200
B	100
C	50

When configuring HA you do not have to change the device priority of any of the cluster units. If all cluster units have the same device priority, when the cluster first starts up the FGCP negotiates to select the cluster unit with the highest serial number to be the primary unit. Clusters also function normally if all units have the same device priority.

You can change the device priority if you want to control the roles that individual units play in the cluster. For example, if you want the same unit to always become the primary unit, set this unit device priority higher than the device priority of other cluster units. Also, if you want a cluster unit to always become a subordinate unit, set this cluster unit device priority lower than the device priority of other cluster units.

If you have a cluster of three units you can set a different priority for each unit to control which unit becomes the primary unit when all three cluster units are functioning and which will be the primary unit when two cluster units are functioning.

The device priority range is 0 to 255. The default device priority is 128.

If you are configuring a virtual cluster, if you have added virtual domains to both virtual clusters, you can set the device priority that the cluster unit has in virtual cluster 1 and virtual cluster 2. If a FortiGate has different device priorities in virtual cluster 1 and virtual cluster 2, the FortiGate may be the primary unit in one virtual cluster and the subordinate unit in the other.

Primary unit selection and the FortiGate serial number

The cluster unit with the highest serial number is more likely to become the primary unit. When first configuring FortiGates to be added to a cluster, if you do not change the device priority of any cluster unit, then the cluster unit with the highest serial number always becomes the primary unit.

Age does take precedence over serial number, so if a cluster unit takes longer to join a cluster for some reason (for example if one cluster unit is powered on after the others), that cluster unit will not become the primary unit because the other units have been in the cluster longer.

Device priority and failed monitored interfaces also take precedence over serial number. A higher device priority means a higher priority. So if you set the device priority of one unit higher or if a monitored interface fails, the cluster will not use the FortiGate serial number to select the primary unit.

Points to remember about primary unit selection

Some points to remember about primary unit selection:

- The FGCP compares primary unit selection criteria in the following order: Failed Monitored interfaces > Age > Device Priority > Serial number. The selection process stops at the first criteria that selects one cluster unit.
- Negotiation and primary unit selection is triggered if a cluster unit fails or if a monitored interface fails.

- If the HA age difference is more than 5 minutes (300 seconds), the cluster unit that is operating longer becomes the primary unit.
- If HA age difference is less than 5 minutes (300 seconds), the device priority and FortiGate serial number selects the cluster unit to become the primary unit.
- Every time a monitored interface fails the HA age of the cluster unit is reset to 0.
- Every time a cluster unit restarts the HA age of the cluster unit is reset to 0.

Temporarily setting a cluster unit to be the primary unit

You can use the following diagnose command to set a cluster unit to be the primary unit.

```
diagnose sys ha set-as-master enable
```

This command is intended for demonstration purposes and not for production use.
This command may not be visible for all FortiOS versions.

When you enter this command, the cluster immediately re-negotiates and the cluster unit on which you entered this command becomes the primary unit. This change is temporary and will be reverted if the cluster unit restarts.

You can also use the following command from the same cluster unit to turn this option off, causing the cluster to renegotiate and select a new primary unit.

```
diagnose sys ha set-as-master disable
```

You can also configure when to disabling the set-as-master setting. For example, to disable the set as master setting on January 25, 2015 you can enter a date after the disable keyword:

```
diagnose sys ha set-as-master disable 2015 01 25
```

HA override

The HA `override` CLI keyword is disabled by default. When `override` is disabled a cluster may not always renegotiate when an event occurs that affects primary unit selection. For example, when `override` is disabled a cluster will not renegotiate when you change a cluster unit device priority or when you add a new cluster unit to a cluster. This is true even if the unit added to the cluster has a higher device priority than any other unit in the cluster. Also, when `override` is disabled a cluster does not negotiate if the new unit added to the cluster has a failed or disconnected monitored interface.

For a virtual cluster configuration, `override` is enabled by default for both virtual clusters when you enable virtual cluster 2. For more information, see [Virtual clusters on page 1463](#).

In most cases you should keep `override` disabled to reduce how often the cluster negotiates. Frequent negotiations may cause frequent traffic interruptions.

However, if you want to make sure that the same cluster unit always operates as the primary unit and if you are less concerned about frequent cluster negotiation you can set its device priority higher than other cluster units and enable `override`.

To enable `override`, connect to each cluster unit CLI (using the `execute ha manage` command) and use the `config system ha` CLI command to enable `override`.

For `override` to be effective, you must also set the device priority highest on the cluster unit that you want to always be the primary unit. To increase the device priority, from the CLI use the `config system ha` command and increase the value of the `priority` keyword to a number higher than the default priority of 128.

You can also increase the device priority from the GUI by going to **System > HA**. To increase the device priority of the primary unit select edit for the primary or subordinate unit and set the **Device Priority** to a number higher than 128.

The `override` setting and device priority value are not synchronized to all cluster units. You must enable override and adjust device priority manually and separately for each cluster unit.

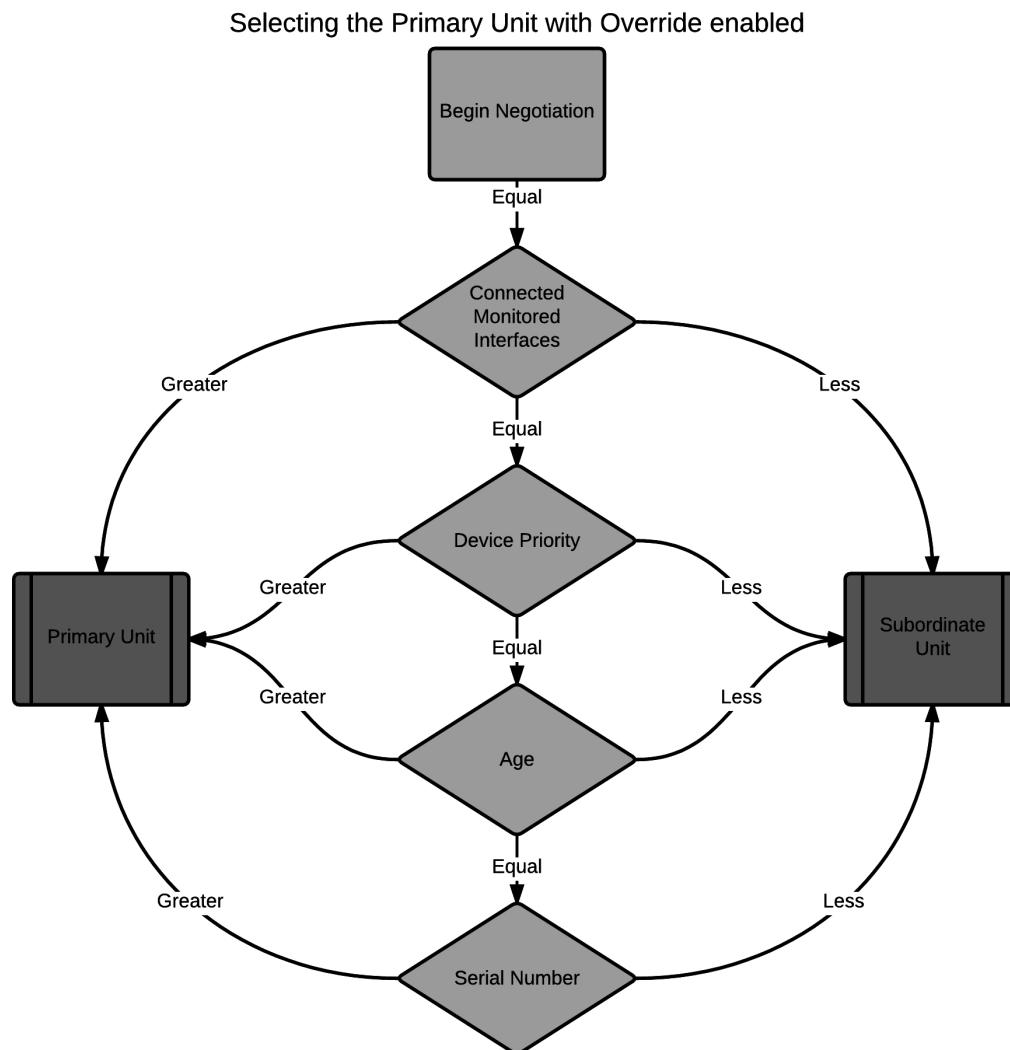

With `override` enabled, the primary unit with the highest device priority will always become the primary unit. Whenever an event occurs that may affect primary unit selection, the cluster negotiates. For example, when `override` is enabled a cluster renegotiates when you change the device priority of any cluster unit or when you add a new unit to a cluster.

Override and primary unit selection

Enabling `override` changes the order of primary unit selection. As shown below, if `override` is enabled, primary unit selection considers device priority before age and serial number. This means that if you set the device priority higher on one cluster unit, with `override` enabled this cluster unit becomes the primary unit even if its age and serial number are lower than other cluster units.

Similar to when `override` is disabled, when `override` is enabled primary unit selection checks for connected monitored interfaces first. So if interface monitoring is enabled, the cluster unit with the most disconnected monitored interfaces cannot become the primary unit, even if the unit has the highest device priority.

If all monitored interfaces are connected (or interface monitoring is not enabled) and the device priority of all cluster units is the same then age and serial number affect primary unit selection.

Controlling primary unit selection using device priority and override

To configure one cluster unit to always become the primary unit you should set its device priority to be higher than the device priorities of the other cluster units and you should enable `override` on all cluster units.

Using this configuration, when the cluster is operating normally the primary unit is always the unit with the highest device priority. If the primary unit fails the cluster renegotiates to select another cluster unit to be the primary unit. If the failed primary unit recovers, starts up again and rejoins the cluster, because `override` is enabled, the cluster renegotiates. Because the restarted primary unit has the highest device priority it once again becomes the primary unit.

In the same situation with `override` disabled, because the age of the failed primary unit is lower than the age of the other cluster units, when the failed primary unit rejoins the cluster it does not become the primary unit. Instead, even though the failed primary unit may have the highest device priority it becomes a subordinate unit because its age is lower than the age of all the other cluster units.

Points to remember about primary unit selection when override is enabled

Some points to remember about primary unit selection when `override` is enabled:

- The FGCP compares primary unit selection criteria in the following order: Failed Monitored Interfaces > Device Priority > Age > Serial number. The selection process stops at the first criteria that selects one cluster unit.
- Negotiation and primary unit selection is triggered whenever an event occurs which may affect primary unit selection. For example negotiation occurs, when you change the device priority, when you add a new unit to a cluster, if a cluster unit fails, or if a monitored interface fails.
- Device priority is considered before age. Otherwise age is handled the same when `override` is enabled.

Configuration changes can be lost if override is enabled

In some cases, when `override` is enabled and you make configuration changes to an HA cluster these changes can be lost. For example, consider the following sequence:

1. A cluster of two FortiGates is operating with `override` enabled.
 - FGT-A: Primary unit with device priority 200 and with `override` enabled
 - FGT-B: Subordinate unit with device priority 100 and with `override` disabled
 - If both units are operating, FGT-A always becomes the primary unit because FGT-A has the highest device priority.
2. FGT-A fails and FGT-B becomes the new primary unit.
3. The administrator makes configuration changes to the cluster.

The configuration changes are made to FGT-B because FGT-B is operating as the primary unit. These configuration changes are not synchronized to FGT-A because FGT-A is not operating.
4. FGT-A is restored and starts up again.
5. The cluster renegotiates and FGT-A becomes the new primary unit.
6. The cluster recognizes that the configurations of FGT-A and FGT-B are not the same.
7. The configuration of FGT-A is synchronized to FGT-B.

The configuration is always synchronized from the primary unit to the subordinate units.
8. The cluster is now operating with the same configuration as FGT-A. The configuration changes made to FGT-B have been lost.

The solution

When `override` is enabled, you can prevent configuration changes from being lost by doing the following:

- Verify that all cluster units are operating before making configuration changes (from the GUI go to **System > HA** to view the cluster members list or from the FortiOS CLI enter `get system ha status`).
- Make sure the device priority of the primary unit is set higher than the device priorities of all other cluster units before making configuration changes.
- Disable `override` either permanently or until all configuration changes have been made and synchronized to all cluster units.

Override and disconnecting a unit from a cluster

A similar scenario to that described above may occur when `override` is enabled and you use the Disconnect from Cluster option from the GUI or the `execute ha disconnect` command from the CLI to disconnect a cluster unit from a cluster.

Configuration changes made to the cluster can be lost when you reconnect the disconnected unit to the cluster. You should make sure that the device priority of the disconnected unit is lower than the device priority of the current primary unit. Otherwise, when the disconnected unit joins the cluster, if `override` is enabled, the cluster renegotiates and the disconnected unit may become the primary unit. If this happens, the configuration of the disconnected unit is synchronized to all other cluster units and any configuration changes made between when the unit was disconnected and reconnected are lost.

Delaying how quickly the primary unit rejoins the cluster when override is enabled

In some cases when `override` is enabled and the unit designated to be the primary unit rejoins the cluster it will become the primary unit too soon and cause traffic disruption. This can happen, for example, if one of the FortiGate interfaces gets its address using PPPoE. If the backup unit is operating as the primary unit and processing traffic, when the primary unit comes up it may need a short time to get a new IP address from the PPPoE server. If the primary unit takes over the cluster before it has an IP address, traffic will be disrupted until the primary unit gets its address.

You can resolve this problem by using the following command to add a wait time. In this example the wait time is 10 seconds. The wait time range is 0 to 3600 seconds and the default wait time is 0 seconds.

```
config system ha
    set override-wait-time 10
end
```

With this wait time configured, after the primary unit is up and running it has 10 seconds to synchronize sessions, get IP address(es) from PPPoE and DHCP servers and so on. After 10 seconds the primary unit sends gratuitous arp packets and all traffic to the cluster is sent to the new primary unit. You can adjust the wait time according to the conditions on your network.

FortiGate HA compatibility with DHCP and PPPoE

FortiGate HA is compatible with DHCP and PPPoE but care should be taken when configuring a cluster that includes a FortiGate interface configured to get its IP address with DHCP or PPPoE. Fortinet recommends that you turn on DHCP or PPPoE addressing for an interface after the cluster has been configured. If an interface is configured for DHCP or PPPoE, turning on high availability may result in the interface receiving an incorrect address or not being able to connect to the DHCP or PPPoE server correctly.

You cannot switch to operate in HA mode if one or more FortiGate interfaces is configured as a PPTP or L2TP client.

You can configure a cluster to act as a DHCP server or a DHCP relay agent. In both active-passive and active-active clusters DHCP relay sessions are always handled by the primary unit. It is possible that a DHCP relay session could be interrupted by a failover. If this occurs the DHCP relay session is not resumed after the failover and the DHCP client may have to repeat the DHCP request.

When a cluster is operating as a DHCP server the primary unit responds to all DHCP requests and maintains the DHCP server address lease database. The cluster also dynamically synchronizes the DHCP server address lease database to the subordinate units. If a failover occurs, the new primary unit will have an up-to-date DHCP server address lease database. Synchronizing the DHCP address lease database prevents the new primary unit from responding incorrectly to new DHCP requests after a failover.

Also, it is possible that when FortiGates first negotiate to form a cluster that a unit that ends up as a subordinate unit in the cluster will have information in its DHCP address lease database that the cluster unit operating as the

primary unit does not have. This can happen if a FortiGate responds to DHCP requests while operating as a standalone unit and then when the cluster is formed this unit becomes a subordinate unit. Because of this possibility, after a cluster is formed the DHCP address lease databases of all of the cluster units are merged into one database which is then synchronized to all cluster units.

HA and distributed clustering

The FGCP supports widely separated cluster units installed in different physical locations. Distributed clusters can have cluster units in different rooms in the same building, different buildings in the same location, or even different geographical sites such as different cities, countries or continents.

Just like any cluster, distributed clusters require heartbeat communication between cluster units. In a distributed cluster this heartbeat communication can take place over the internet or over other transmission methods including satellite linkups.

Most Data Center Interconnect (DCI) or MPLS-based solutions that support layer 2 extensions between the remote data centers should also support HA heartbeat communication between the FortiGates in the distributed locations. Using VLANs and switches in promiscuous mode to pass all traffic between the locations can also be helpful.

HA heartbeat IP addresses are not configurable so the heartbeat interfaces have to be able to communicate over the same subnet. See [HA heartbeat interface IP addresses on page 1526](#).

Because of the possible distance it may take a relatively long time for heartbeat packets to be transmitted between cluster units. This could lead to a split brain scenario. To avoid a split brain scenario you can increase the heartbeat interval so that the cluster expects extra time between heartbeat packets. A general rule is to configure the failover time to be longer than the max latency. You could also increase the `hb-lost-threshold` to tolerate losing heartbeat packets if the network connection is less reliable.

In addition you could use different link paths for heartbeat packets to optimize HA heartbeat communication. You could also configure QoS on the links used for HA heartbeat traffic to make sure heartbeat communication has the highest priority.

For information about changing the heartbeat interval and other heartbeat related settings, see [Modifying heartbeat timing on page 1528](#).

Clusters of three or four FortiGates

The FGCP supports a cluster of two, three, or four FortiGates. You can add more than two units to a cluster to improve reliability: if two cluster units fail the third will continue to operate and so on. A cluster of three or four units in active-active mode may improve performance since another cluster unit is available for security profile processing. However, active-active FGCP HA results in diminishing performance returns as you add units to the cluster, so the additional performance achieved by adding the third cluster unit may not be worth the cost.

There are no special requirements for clusters of more than two units. Here are a few recommendations though:

- The matching heartbeat interfaces of all of the cluster units must be able to communicate with each other. So each unit's matching heartbeat interface should be connected to the same switch. If the ha1 interface is used for heartbeat communication, then the ha1 interfaces of all of the units in the cluster must be connected together so communication can happen between all of the cluster units over the ha1 interface.
- Redundant heartbeat interfaces are recommended. You can reduce the number of points of failure by connecting each matching set of heartbeat interfaces to a different switch. This is not a requirement; however, and you can connect both heartbeat interfaces of all cluster units to the same switch. However, if that switch fails the cluster will stop forwarding traffic.
- For any cluster, a dedicated switch for each heartbeat interface is recommended because of the large volume of heartbeat traffic and to keep heartbeat traffic off of other networks, but it is not required.
- Full mesh HA can scale to three or four FortiGates. Full mesh HA is not required if you have more than 2 units in a cluster.
- Virtual clustering can only be done with two FortiGates.

Connecting a cluster of three FortiGates

This example shows how to connect a cluster of three FortiGates where:

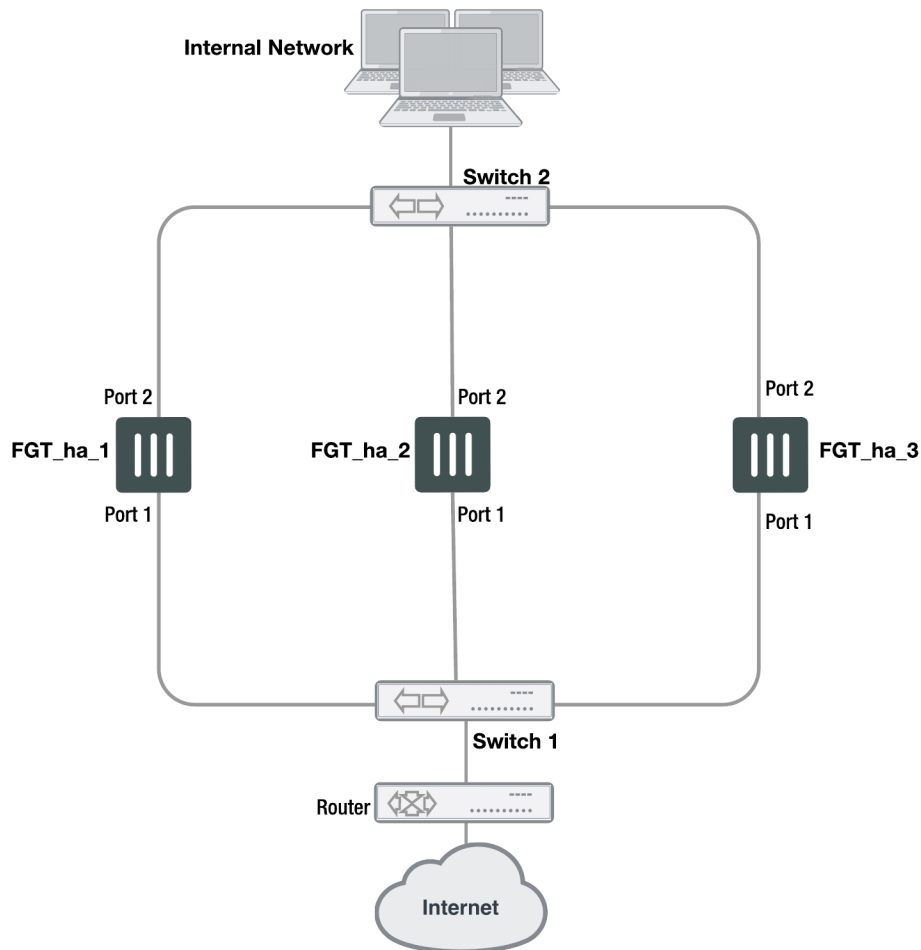

- Port1 connects the cluster to the internet
- Port2 connects the cluster to the internal network
- Port3 and Port4 are the heartbeat interfaces

Use the following steps to connect the cluster units to each other and to their networks:

1. Connect the network interfaces:

- Connect the port1 interface of each FortiGate to the same switch (Switch 1) and connect this switch to the internet.
- Connect the port2 interface of each FortiGate to the same switch (Switch 2) and connect this switch to the internal Network.

Connecting the network interfaces (cluster of three FortiGates)

2. Connect the heartbeat interfaces:

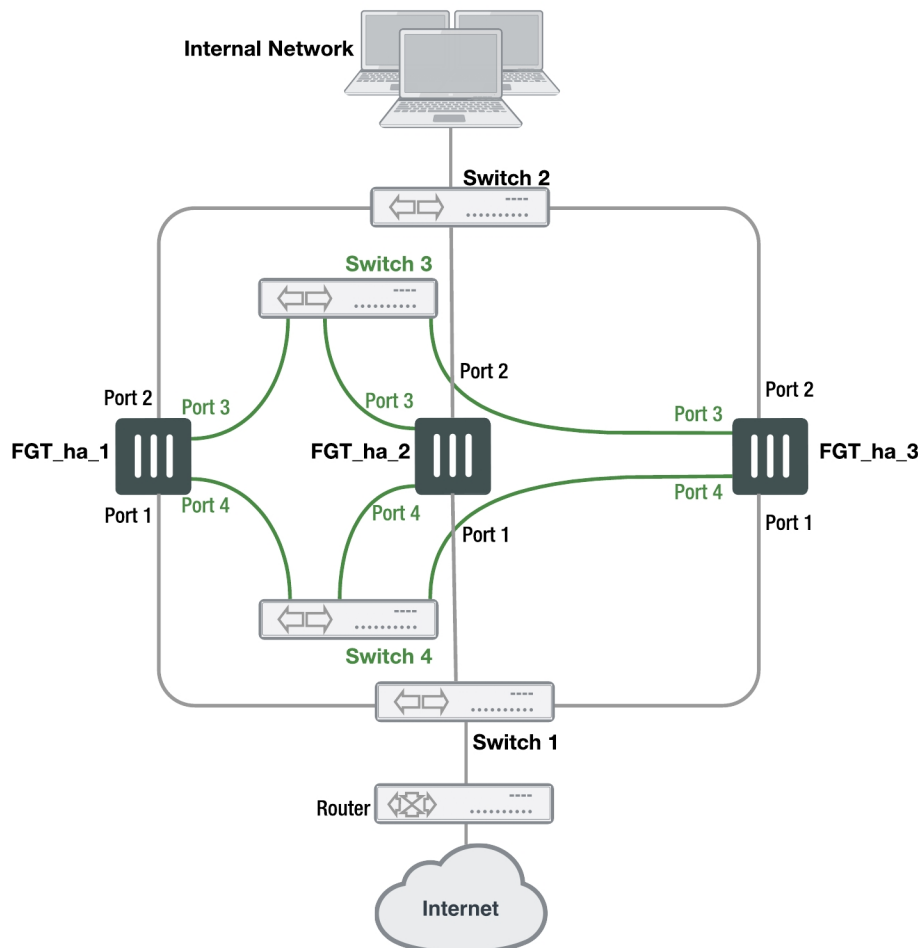

- Connect the port3 interface of each FortiGate to the same switch (Switch 3)
- Connect the port4 interface of each FortiGate to the same switch (Switch 4)

Connecting the heartbeat interfaces (cluster of three FortiGates)

The network and heartbeat connections when combined into one diagram appear like the following:

Network and heartbeat interface connections (cluster of three FortiGates)

Disk storage configuration and HA

If your cluster units include storage disks (for example for storing log messages, WAN optimization data and web caching) all cluster units must have identical storage disk configurations. This means each cluster unit must have same number of disks (including AMC and FortiGate Storage Module (FSM) hard disks) and also means that matching disks in each cluster unit must be the same size, have the same format, and have the same number of partitions.

In most cases the default hard disk configuration of the cluster units will be compatible. However, a hard disk formatted by an older FortiGate firmware version may not be compatible with a hard disk formatted by a more recent firmware version. Problems may also arise if you have used the `execute scsi-dev` command to add or change hard disk protections.

If a cluster unit CLI displays hard disk compatibility messages, you may need to use the `execute scsi-dev delete` command to delete partitions. You can also use the `execute formatlogdisk` command to

reformat disks. In some cases after deleting all partitions and reformatting the disks, you may still see disk incompatibility messages. If this happens, visit the [Fortinet Support](#) website assistance.

FGCP high availability best practices

Fortinet suggests the following practices related to high availability:

- Use Active-Active HA to distribute TCP and UTM sessions among multiple cluster units. An active-active cluster may have higher throughput than a standalone FortiGate unit or than an active-passive cluster.
- Use a different host name on each FortiGate unit when configuring an HA cluster. Fewer steps are required to add host names to each cluster unit before configuring HA and forming a cluster.
- Consider adding an Alias to the interfaces used for the HA heartbeat so that you always get a reminder about what these interfaces are being used for.
- Enabling `load-balance-all` can increase device and network load since more traffic is load-balanced. This may be appropriate for use in a deployment using the firewall capabilities of the FortiGate unit and IPS but no other content inspection.
- An advantage of using session pickup is that non-content inspection sessions will be picked up by the new primary unit after a failover. The disadvantage is that the cluster generates more heartbeat traffic to support session pickup as a larger portion of the session table must be synchronized. Session pickup should be configured only when required and is not recommended for use with SOHO FortiGate models. Session pickup should only be used if the primary heartbeat link is dedicated (otherwise the additional HA heartbeat traffic could affect network performance).
- If session pickup is not selected, after a device or link failover all sessions are briefly interrupted and must be re-established at the application level after the cluster renegotiates. For example, after a failover, users browsing the web can just refresh their browsers to resume browsing. Users downloading large files may have to restart their download after a failover. Other protocols may experience data loss and some protocols may require sessions to be manually restarted. For example, a user downloading files with FTP may have to either restart downloads or restart their FTP client.
- If you need to enable session pickup, consider enabling `session-pickup-delay` to improve performance by reducing the number of sessions that are synchronized. See [Improving session synchronization performance on page 1](#).
- Consider using the `session-sync-dev` option to move session synchronization traffic off the HA heartbeat link to one or more dedicated session synchronization interfaces. See [Improving session synchronization performance on page 1](#).
- To avoid unpredictable results, when you connect a switch to multiple redundant or aggregate interfaces in an active-passive cluster you should configure separate redundant or aggregate interfaces on the switch; one for each cluster unit.
- Use SNMP, syslog, or email alerts to monitor a cluster for failover messages. Alert messages about cluster failovers may help find and diagnose network problems quickly and efficiently.

Heartbeat interfaces

Fortinet suggests the following practices related to heartbeat interfaces:

Do not use a FortiGate switch port for the HA heartbeat traffic. This configuration is not supported.

- Configure at least two heartbeat interfaces and set these interfaces to have different priorities.
- For clusters of two FortiGate units, as much as possible, heartbeat interfaces should be directly connected using patch cables (without involving other network equipment such as switches). If switches have to be used they should not be used for other network traffic that could flood the switches and cause heartbeat delays.
 - If you cannot use a dedicated switch, the use of a dedicated VLAN can help limit the broadcast domain to protect the heartbeat traffic and the bandwidth it creates.
- For clusters of three or four FortiGate units, use switches to connect heartbeat interfaces. The corresponding heartbeat interface of each FortiGate unit in the cluster must be connected to the same switch. For improved redundancy use a different switch for each heartbeat interface. In that way if the switch connecting one of the heartbeat interfaces fails or is unplugged, heartbeat traffic can continue on the other heartbeat interfaces and switch.
- Isolate heartbeat interfaces from user networks. Heartbeat packets contain sensitive cluster configuration information and can consume a considerable amount of network bandwidth. If the cluster consists of two FortiGate units, connect the heartbeat interfaces directly using a crossover cable or a regular Ethernet cable. For clusters with more than two units, connect heartbeat interfaces to a separate switch that is not connected to any network.
- If heartbeat traffic cannot be isolated from user networks, enable heartbeat message encryption and authentication to protect cluster information. See [Enabling or disabling HA heartbeat encryption and authentication on page 1529](#).
- Configure and connect redundant heartbeat interfaces so that if one heartbeat interface fails or becomes disconnected, HA heartbeat traffic can continue to be transmitted using the backup heartbeat interface. If heartbeat communication fails, all cluster members will think they are the primary unit resulting in multiple devices on the network with the same IP addresses and MAC addresses (condition referred to as *Split Brain*) and communication will be disrupted until heartbeat communication can be reestablished.
- Do not monitor dedicated heartbeat interfaces; monitor those interfaces whose failure should trigger a device failover.
- Where possible at least one heartbeat interface should not be connected to an NP4 or NP6 processor to avoid NP4 or NP6-related problems from affecting heartbeat traffic.
- Where possible, the heartbeat interfaces should not be connected to an NP4 or NP6 processor that is also processing network traffic.
- Where possible, each heartbeat interface should be connected to a different NP4 or NP6 processor.
- Any FortiGate interface can be used as a heartbeat interface including 10/100/1000Base-T, SFP, QSFP fiber and copper, and so on. If you set up two or more interfaces as heartbeat interfaces each interface can be a different type and speed.

Interface monitoring (port monitoring)

Fortinet suggests the following practices related to interface monitoring (also called port monitoring):

- Wait until a cluster is up and running and all interfaces are connected before enabling interface monitoring. A monitored interface can easily become disconnected during initial setup and cause failovers to occur before the cluster is fully configured and tested.
- Monitor interfaces connected to networks that process high priority traffic so that the cluster maintains connections to these networks if a failure occurs.
- Avoid configuring interface monitoring for all interfaces.
- Supplement interface monitoring with remote link failover. Configure remote link failover to maintain packet flow if a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails. See [Remote link failover on page 1556](#).

FGCP HA terminology

The following HA-specific terms are used in this document.

Cluster

A group of FortiGates that act as a single virtual FortiGate to maintain connectivity even if one of the FortiGates in the cluster fails.

Cluster unit

A FortiGate operating in a FortiGate HA cluster.

Device failover

Device failover is a basic requirement of any highly available system. Device failover means that if a device fails, a replacement device automatically takes the place of the failed device and continues operating in the same manner as the failed device.

Failover

A FortiGate taking over processing network traffic in place of another unit in the cluster that suffered a device failure or a link failure.

Failure

A hardware or software problem that causes a FortiGate or a monitored interface to stop processing network traffic.

FGCP

The FortiGate clustering protocol (FGCP) that specifies how the FortiGates in a cluster communicate to keep the cluster operating.

Full mesh HA

Full mesh HA is a method of removing single points of failure on a network that includes an HA cluster. FortiGate models that support redundant interfaces can be used to create a cluster configuration called full mesh HA. Full mesh HA includes redundant connections between all network components. If any single component or any single connection fails, traffic switches to the redundant component or connection.

HA virtual MAC address

When operating in HA mode, all of the interfaces of the primary unit acquire the same HA virtual MAC address. All communications with the cluster must use this MAC address. The HA virtual MAC address is set according to the group ID.

Heartbeat

Also called FGCP heartbeat or HA heartbeat. The heartbeat constantly communicates HA status and synchronization information to make sure that the cluster is operating properly.

Heartbeat device

An Ethernet network interface in a cluster that is used by the FGCP for heartbeat communications among cluster units.

Heartbeat failover

If an interface functioning as the heartbeat device fails, the heartbeat is transferred to another interface also configured as an HA heartbeat device.

Hello state

In the hello state a cluster unit has powered on in HA mode, is using HA heartbeat interfaces to send hello packets, and is listening on its heartbeat interfaces for hello packets from other FortiGates. Hello state may appear in HA log messages.

High availability

The ability that a cluster has to maintain a connection when there is a device or link failure by having another unit in the cluster take over the connection, without any loss of connectivity. To achieve high availability, all FortiGates in the cluster share session and configuration information.

Interface monitoring

You can configure interface monitoring (also called port monitoring) to monitor FortiGate interfaces to verify that the monitored interfaces are functioning properly and connected to their networks. If a monitored interface fails or is disconnected from its network the interface leaves the cluster and a link failover occurs. For more information about interface monitoring, see [Link failover \(port monitoring or interface monitoring\)](#) on page 1549.

Link failover

Link failover means that if a monitored interface fails, the cluster reorganizes to re-establish a link to the network that the monitored interface was connected to and to continue operating with minimal or no disruption of network traffic.

Load balancing

Also known as active-active HA. All units in the cluster process network traffic. The FGCP employs a technique similar to unicast load balancing. The primary unit interfaces are assigned virtual MAC addresses which are associated on the network with the cluster IP addresses. The primary unit is the only cluster unit to receive packets sent to the cluster. The primary unit can process packets itself, or propagate them to subordinate units according to a load balancing schedule. Communication between the cluster units uses the actual cluster unit MAC addresses.

Monitored interface

An interface that is monitored by a cluster to make sure that it is connected and operating correctly. The cluster monitors the connectivity of this interface for all cluster units. If a monitored interface fails or becomes disconnected from its network, the cluster will compensate.

Primary unit

Also called the primary cluster unit, this cluster unit controls how the cluster operates. The primary unit sends hello packets to all cluster units to synchronize session information, synchronize the cluster configuration, and to synchronize the cluster routing table. The hello packets also confirm for the subordinate units that the primary unit is still functioning.

The primary unit also tracks the status of all subordinate units. When you start a management connection to a cluster, you connect to the primary unit.

In an active-passive cluster, the primary unit processes all network traffic. If a subordinate unit fails, the primary unit updates the cluster configuration database.

In an active-active cluster, the primary unit receives all network traffic and re-directs this traffic to subordinate units. If a subordinate unit fails, the primary unit updates the cluster status and redistributes load balanced traffic to other subordinate units in the cluster.

The FortiGate firmware uses the term master to refer to the primary unit.

Session failover

Session failover means that a cluster maintains active network sessions after a device or link failover. FortiGate HA does not support session failover by default. To enable session failover you must change the HA configuration to select Enable Session Pick-up.

Session pickup

If you enable session pickup for a cluster, if the primary unit fails or a subordinate unit in an active-active cluster fails, all communication sessions with the cluster are maintained or picked up by the cluster after the cluster negotiates to select a new primary unit.

If session pickup is not a requirement of your HA installation, you can disable this option to save processing resources and reduce the network bandwidth used by HA session synchronization. In many cases interrupted sessions will resume on their own after a failover even if session pickup is not enabled. You can also enable session pickup delay to reduce the number of sessions that are synchronized by session pickup.

Standby state

A subordinate unit in an active-passive HA cluster operates in the standby state. In a virtual cluster, a subordinate virtual domain also operates in the standby state. The standby state is actually a hot-standby state because the subordinate unit or subordinate virtual domain is not processing traffic but is monitoring the primary unit session table to take the place of the primary unit or primary virtual domain if a failure occurs.

In an active-active cluster all cluster units operate in a work state.

When standby state appears in HA log messages this usually means that a cluster unit has become a subordinate unit in an active-passive cluster or that a virtual domain has become a subordinate virtual domain.

State synchronization

The part of the FGCP that maintains connections after failover.

Subordinate unit

Also called the subordinate cluster unit, each cluster contains one or more cluster units that are not functioning as the primary unit. Subordinate units are always waiting to become the primary unit. If a subordinate unit does not receive hello packets from the primary unit, it attempts to become the primary unit.

In an active-active cluster, subordinate units keep track of cluster connections, keep their configurations and routing tables synchronized with the primary unit, and process network traffic assigned to them by the primary unit. In an active-passive cluster, subordinate units do not process network traffic. However, active-passive subordinate units do keep track of cluster connections and do keep their configurations and routing tables synchronized with the primary unit.

The FortiGate firmware uses the terms slave and subsidiary unit to refer to a subordinate unit.

Virtual clustering

Virtual clustering is an extension of the FGCP for FortiGates operating with multiple VDOMS enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

Work state

The primary unit in an active-passive HA cluster, a primary virtual domain in a virtual cluster, and all cluster units in an active-active cluster operate in the work state. A cluster unit operating in the work state processes traffic, monitors the status of the other cluster units, and tracks the session table of the cluster.

When work state appears in HA log messages this usually means that a cluster unit has become the primary unit or that a virtual domain has become a primary virtual domain.

FGCP support for OCVPN

You can set up a One-click VPN (OCVPN) on an FGCP cluster without any special configuration steps. When you add an OCVPN configuration, the FGCP synchronizes the configuration to all of the FortiGates in the cluster. When an OCVPN tunnel comes up between a remote client and the cluster, the OCVPN communicates with the primary FortiGate. The FGCP then synchronizes the VPN sessions to the other FortiGates in the cluster. If a failover occurs, the OCVPN sessions fail over to the new primary FortiGate and the OCVPN sessions continue with only minor interruptions.

A standalone FortiGate OCVPN configuration is not compatible with an FGCP OCVPN configuration. If you set up OCVPN on a stand-alone FortiGate, before you add this stand-alone FortiGate to an FGCP cluster you must disable any OCVPN configurations, set up HA, and then re-create the OCVPN configurations after the cluster is established.

The reverse is also true. If you decide to convert a cluster with an OCVPN configuration to a stand-alone FortiGate, you need to remove the OCVPN configuration, set up the standalone FortiGate and then re-create the OCVPN configuration on the standalone FortiGate.

HA GUI options

Go to **System > HA** to change HA options. You can set the following options to put a FortiGate into HA mode. You can also change any of these options while the cluster is operating.

You can configure HA options for a FortiGate with virtual domains (VDOMs) enabled by logging into the GUI as the global admin administrator and going to **System > HA**.

If already operating in HA mode, go to **System > HA** to display the cluster members list. You can then edit the primary unit to change HA settings.

Go to **System > HA > View HA Statistics** to view statistics about cluster operation.

Most virtual cluster HA options are the same as normal HA options. However, virtual clusters include VDOM partitioning options. Other differences between configuration options for regular HA and for virtual clustering HA are described below and see [Virtual clusters on page 1463](#).

FortiGate HA is compatible with DHCP and PPPoE but care should be taken when configuring a cluster that includes a FortiGate interface configured to get its IP address with DHCP or PPPoE. Fortinet recommends that you turn on DHCP or PPPoE addressing for an interface after the cluster has been configured. If an interface is configured for DHCP or PPPoE, turning on high availability may result in the interface receiving an incorrect address or not being able to connect to the DHCP or PPPoE server correctly.

Mode

Select an HA mode for the cluster or return the FortiGate in the cluster to standalone mode. When configuring a cluster, you must set all members of the HA cluster to the same HA mode. You can select **Standalone** (to disable HA), **Active-Passive**, or **Active-Active**.

If virtual domains are enabled you can select **Active-Passive** or **Standalone**.

Device priority

Optionally set the device priority of the cluster FortiGate. Each FortiGate in a cluster can have a different device priority. During HA negotiation, the FortiGate with the highest device priority usually becomes the primary unit.

In a virtual cluster configuration, each cluster FortiGate can have two different device priorities, one for each virtual cluster. During HA negotiation, the FortiGate with the highest device priority in a virtual cluster becomes the primary FortiGate for that virtual cluster.

Changes to the device priority are not synchronized. You can accept the default device priority when first configuring a cluster.

Synchronize management VDOM

This options appears if you have enabled multiple VDOMS and set a VDOM other than the root VDOM to be the management VDOM. You can disable this option to prevent the management VDOM configuration from being synchronized between cluster units in the virtual cluster. This allows you to add an interface to the VDOM in each

cluster unit and then to give the Interface a different IP address in each cluster unit, allowing you to manage each cluster unit separately.

You can also enable this feature using the following command:

```
config system ha
    set standalone-mgmt-vdom enable
end
```

Group name

Enter a name to identify the cluster. The maximum length of the group name is 32 characters. The group name must be the same for all cluster units before the cluster units can form a cluster. After a cluster is operating, you can change the group name. The group name change is synchronized to all cluster units.

Password

Enter a password to identify the cluster. The password must be the same for all cluster FortiGates before the cluster FortiGates can form a cluster.

Two clusters on the same network must have different passwords.

The password is synchronized to all cluster units in an operating cluster. If you change the password of one cluster unit the change is synchronized to all cluster units.

Session pickup

Select to enable session pickup so that if the primary unit fails, sessions are picked up by the cluster unit that becomes the new primary unit.

You must enable session pickup for session failover protection. If you do not require session failover protection, leaving session pickup disabled may reduce HA CPU usage and reduce HA heartbeat network bandwidth usage. See [Session failover \(session pick-up\) on page 1](#).

Monitor interfaces

Select to enable or disable monitoring FortiGate interfaces to verify the monitored interfaces are functioning properly and are connected to their networks. See [Link failover \(port monitoring or interface monitoring\) on page 1549](#).

If a monitored interface fails or is disconnected from its network, the interface leaves the cluster and a link failover occurs. The link failover causes the cluster to reroute the traffic being processed by that interface to the same interface of another cluster FortiGate that still has a connection to the network. This other cluster FortiGate becomes the new primary unit.

Interface monitoring (also called port monitoring) is disabled by default. Leave interface monitoring disabled until the cluster is operating and then only enable interface monitoring for connected interfaces.

You can monitor up to 64 interfaces.

Heartbeat interfaces

Enable or disable HA heartbeat communication for each interface in the cluster and set the heartbeat interface priority. The heartbeat interface with the highest priority processes all heartbeat traffic. If two or more heartbeat interfaces have the same priority, the heartbeat interface with the lowest hash map order value processes all heartbeat traffic. The GUI lists interfaces in alphanumeric order:

- port1
- port2 through 9
- port10

Hash map order sorts interfaces in the following order:

- port1
- port10
- port2 through port9

The default heartbeat interface configuration is different for each FortiGate model. This default configuration usually sets the priority of two heartbeat interfaces to 50. You can accept the default heartbeat interface configuration or change it as required.

The heartbeat interface priority range is 0 to 512. The default priority when you select a new heartbeat interface is 0.

You must select at least one heartbeat interface. If heartbeat communication is interrupted, the cluster stops processing traffic. See [HA heartbeat and communication between cluster units on page 1523](#).

You can select up to 8 heartbeat interfaces. This limit only applies to units with more than 8 physical interfaces.

Management interface reservation

You can provide direct management access to individual cluster units by reserving a management interface as part of the HA configuration. Once this management interface is reserved, you can configure a different IP address, administrative access and other interface settings for this interface for each cluster unit. You can also specify static routing settings for this interface. Then by connecting this interface of each cluster unit to your network you can manage each cluster unit separately from a different IP address. See [Managing individual cluster units using a reserved out-of-band management interface on page 1488](#).

VDOM partitioning

If you are configuring virtual clustering, you can set the virtual domains to be in virtual cluster 1 and the virtual domains to be in virtual cluster 2. The root virtual domain must always be in virtual cluster 1.

Secondary cluster settings

If you are configuring virtual clustering you can set the device priority and configure interface monitoring for the secondary virtual cluster.

FGCP configuration examples and troubleshooting

This chapter contains general procedures and descriptions as well as detailed configuration examples that describe how to configure FortiGate HA clusters. Some of the examples are available as cookbook recipes and this chapter provides introductions and links to the cookbook recipes.

About the examples in this chapter

The procedures in this chapter describe some of many possible sequences of steps for configuring HA clustering. As you become more experienced with FortiOS HA you may choose to use a different sequence of configuration steps.

For simplicity, many of these procedures assume that you are starting with new FortiGates set to the factory default configuration. However, starting from the default configuration is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

The examples in this chapter include example values only. In most cases you will substitute your own values. The examples in this chapter also do not contain detailed descriptions of configuration parameters.

How to set up FGCP clustering (recommended steps)

The following recipe describes how to enhance the reliability of a network protected by a FortiGate by adding a second FortiGate and setting up a FortiGate Clustering Protocol (FGCP) High Availability cluster.

High Availability with FGCP (Expert)

The following cookbook recipe also describes how to add a backup FortiGate to a previously installed FortiGate, to form a high availability (HA) cluster to improve network reliability. This recipe takes a higher-level approach using the GUI to configure HA.

High availability with two FortiGates

Adding a third FortiGate to an operating cluster and switching to active-active HA

This recipe describes how to add a third FortiGate to an already established FGCP cluster and how to configure active-active HA for that cluster.

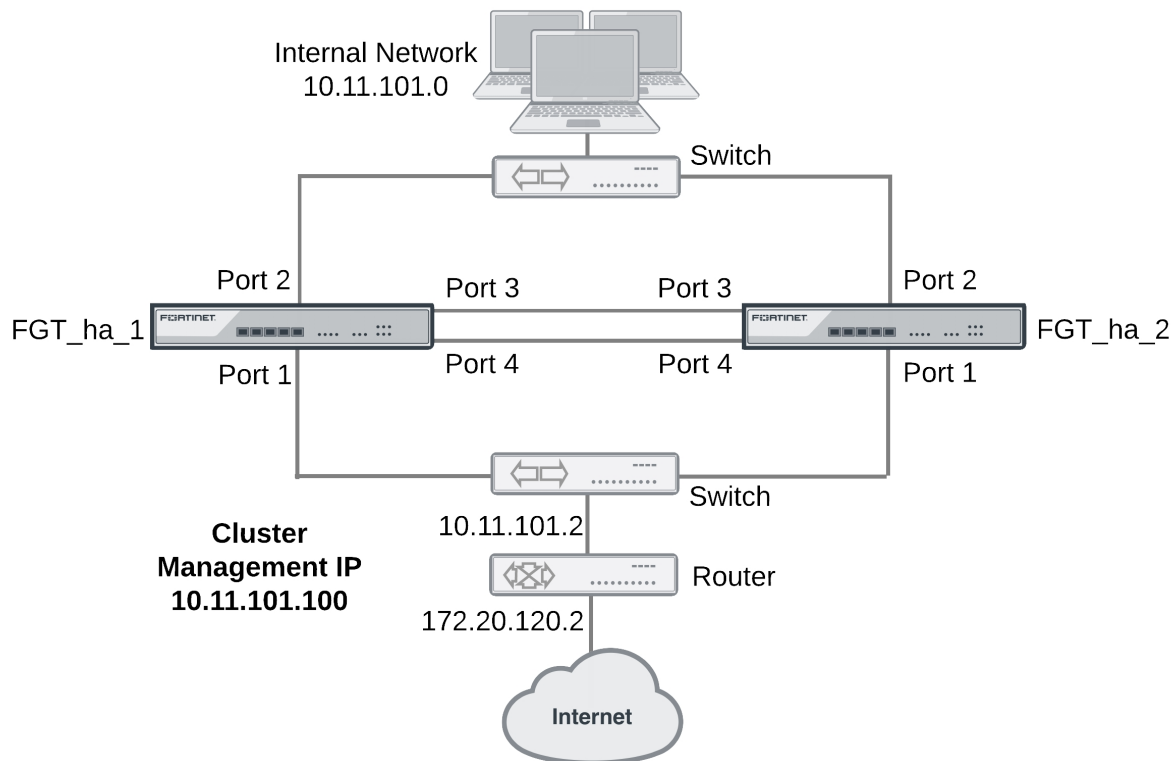

Adding a third FortiGate to an FGCP cluster

Active-active HA cluster in transparent mode

This section describes a simple HA network topology that includes an HA cluster of two generic FortiGates installed between an internal network and the internet and running in transparent mode.

Example transparent mode HA network topology

The figure below shows a transparent mode FortiGate HA cluster consisting of two FortiGates (FGT_ha_1 and FGT_ha_2) installed between the internet and internal network. The topology includes a router that performs NAT between the internal network and the internet. The cluster management IP address is 10.11.101.100.

transparent mode HA network topology

Port3 and port4 are used as the heartbeat interfaces. Because the cluster consists of two FortiGates, you can make the connections between the heartbeat interfaces using crossover cables. You could also use switches and regular ethernet cables.

General configuration steps

This section includes GUI and CLI procedures. These procedures assume that the FortiGates are running the same FortiOS firmware build and are set to the factory default configuration.

In this example, the configuration steps are identical to the NAT/Route mode configuration steps until the cluster is operating. When the cluster is operating, you can switch to transparent mode and add basic configuration settings to cluster.

General configuration steps

1. Apply licenses to the FortiGates to become the cluster.
2. Configure the FortiGates for HA operation.
 - Optionally change each unit's host name.
 - Configure HA.
2. Connect the cluster to the network.
3. Confirm that the cluster units are operating as a cluster.
4. Switch the cluster to transparent mode and add basic configuration settings to the cluster.

- Switch to transparent mode, add the management IP address and a default route.
- Add a password for the admin administrative account.
- View cluster status from the GUI or CLI.

Configuring a transparent mode active-active cluster of two FortiGates - GUI

Use the following procedures to configure the FortiGates for HA operation using the FortiGate GUI. These procedures assume you are starting with two FortiGates with factory default settings.

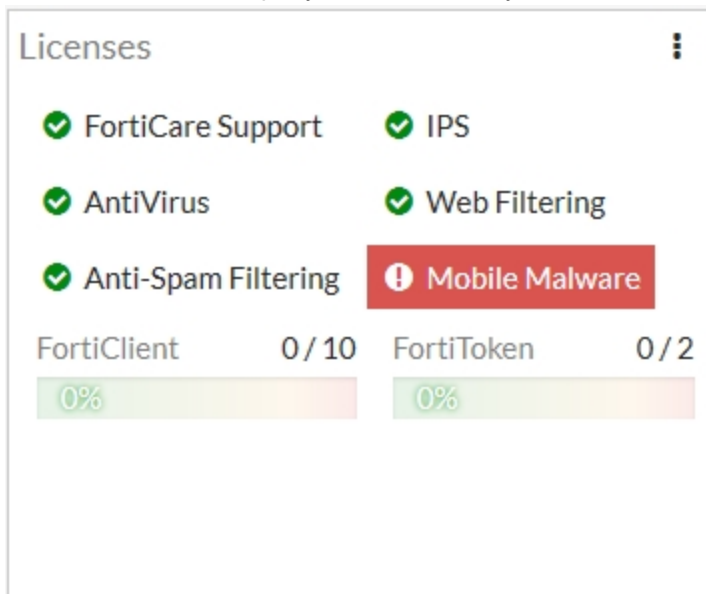

Waiting until you have established the cluster to switch to transparent mode means fewer configuration steps because you can switch the mode of the cluster in one step.

To configure the first FortiGate (host name FGT_ha_1)

1. Register and apply licenses to the FortiGate before configuring it for HA operation. This includes licensing for **FortiCare Support**, **IPS**, **AntiVirus**, **Web Filtering**, **Mobile Malware**, **FortiClient**, **FortiCloud**, and additional **virtual domains** (VDOMs). All FortiGates in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs. **FortiToken** licenses can be added at any time because they are synchronized to all cluster members.

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license.

You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed, third-party certificates are synchronized to the backup FortiGate.

2. Click on the System Information dashboard widget and select **Configure settings** in **System > Settings**.
3. Enter a new Host Name for this FortiGate.

New Name	FGT_ha_1
-----------------	----------

4. Select **OK**.
5. Go to **System > HA** and change the following settings:

Mode	Active-Active
Group Name	example2.com
Password	HA_pass_2

This is the minimum recommended configuration for an active-active HA cluster. You can configure other HA options at this point, but if you wait until the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

6. Select **OK**.

The FortiGate negotiates to establish an HA cluster. When you select **OK** you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port2 interface virtual MAC: 00-09-0f-09-00-01
- port3 interface virtual MAC: 00-09-0f-09-00-02
- port4 interface virtual MAC: 00-09-0f-09-00-03

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

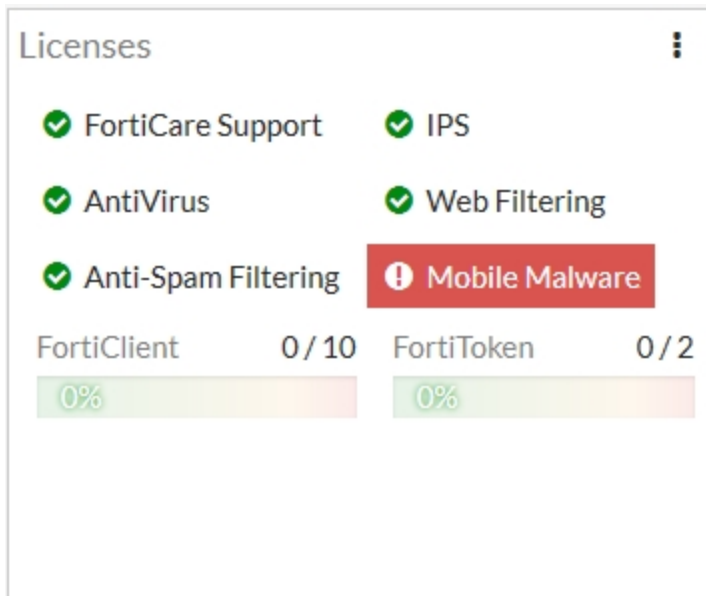

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (MAC) and the port1 permanent MAC address (Permanent_HWaddr):

```
get hardware nic port1
.
.
.
Current_HAaddr    00:09:0f:09:00:00
Permanent_HWaddr  02:09:0f:78:18:c9
.
.
.
```

10. Power off the first FortiGate.

To configure the second FortiGate (host name FGT_ha_2)

1. Register and apply licenses to the FortiGate before configuring it for HA operation.

2. Click on the System Information dashboard widget and select **Configure settings** in **System > Settings**.
3. Enter a new Host Name for this FortiGate.

New Name	FGT_ha_2
-----------------	----------

4. Select **OK**.
5. Go to **System > HA** and change the following settings:

Mode	Active-Active
Group Name	example2.com
Password	HA_pass_2

6. Select **OK**.

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

7. Power off the second FortiGate.

To connect the cluster to the network

1. Connect the port1 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internet.
2. Connect the port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.

3. Connect the port3 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To switch the cluster to transparent mode

Switching from NAT/Route to transparent mode involves adding the transparent mode management IP address and default route.

This is the minimum recommended configuration for an active-active HA cluster. You can configure other HA options at this point, but if you wait until the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

1. Start a web browser and browse to the address `https://192.168.1.99` (remember to include the “s” in `https://`).
The FortiGate Login is displayed.
2. Type admin in the Name field and select Login.
3. Under System Information, beside **Operation Mode** select **Change**.
4. Set Operation Mode to transparent.
5. Configure basic transparent mode settings.

Operation Mode	Transparent
Management IP/Mask	10.11.101.100/24
Default Gateway	10.11.101.2

6. Select **Apply**.
The cluster switches to operating in transparent mode. The virtual MAC addresses assigned to the cluster interfaces do not change.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

Once the cluster is operating, because configuration changes are synchronized to all cluster units, configuring the cluster is the same as configuring an individual FortiGate. You could have performed the following configuration steps separately on each FortiGate before you connected them to form a cluster.

1. Start a web browser and browse to the address `https://10.11.101.100` (remember to include the “s” in `https://`).

The FortiGate Login is displayed.

2. Type **admin** in the Name field and select **Login**.

The FortiGate dashboard is displayed.

The HA Status dashboard widget displays how long the cluster has been operating (Uptime) and the time since the last failover occurred (State Changed). You can hover over the State Changed time to see the event that caused the state change. You can also click on the HA Status dashboard widget to configure HA settings or to get a listing of the most recent HA events recorded by the cluster.

3. Go to **System > HA** to view the cluster members list.

The list shows both cluster units, their host names, their roles in the cluster, and their device priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGates are not functioning as a cluster. See [Troubleshooting HA clusters on page 1458](#) to troubleshoot the cluster.

To add basic configuration settings to the cluster

Use the following steps to configure the cluster. Note that the following are example configuration steps only and do not represent all of the steps required to configure the cluster for a given network.

1. Log into the cluster GUI.
2. Go to **System > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.

You added a default gateway when you switched to transparent mode so you don't need to add a default route as part of the basic configuration of the cluster at this point.

Configuring a transparent mode active-active cluster of two FortiGates - CLI

Use the following procedures to configure the FortiGates for transparent mode HA operation using the FortiGate CLI.

To configure each FortiGate for HA operation

1. Power on the FortiGate.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal, enter a name for the connection, and select **OK**.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select **OK**.
5. Select the following port settings and select **OK**.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

6. Press **Enter** to connect to the FortiGate CLI.

The FortiGate CLI login prompt appears. If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.

7. Type `admin` and press **Enter** twice.

8. Register and apply licenses to the FortiGate.

9. Change the host name for this FortiGate. For example:

```
config system global
  set hostname FGT_ha_1
end
```

10. Configure HA settings.

```
config system ha
  set mode a-a
  set group-name example2.com
  set password HA_pass_2
end
```

This is the minimum recommended configuration for an active-active HA cluster. You can also configure other HA options, but if you wait until after the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

The FortiGate negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port2 interface virtual MAC: 00-09-0f-09-00-01
- port3 interface virtual MAC: 00-09-0f-09-00-02
- port4 interface virtual MAC: 00-09-0f-09-00-03

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate

interface. For example, use the following command to view the port1 interface virtual MAC address (MAC) and the port1 permanent MAC address (Permanent_HWaddr):

```
get hardware nic port1
.
.
.
Current_HAaddr    00:09:0f:09:00:00
Permanent_HWaddr  02:09:0f:78:18:c9
.
.
.
```

10. Display the HA configuration (optional).

```
get system ha
group-id : 0
group-name : example2.com
mode : a-a
password : *
hbdev : "port3" 50 "port4" 50
session-sync-dev :
route-ttl : 10
route-wait : 0
route-hold : 10
sync-config : enable
encryption : disable
authentication : disable
hb-interval : 2
hb-lost-threshold : 20
hello-holddown : 20
arps : 5
arps-interval : 8
session-pickup : disable
update-all-session-timer: disable
session-sync-daemon-number: 1
link-failed-signal : disable
uninterruptible-upgrade: enable
ha-mgmt-status : disable
ha-eth-type : 8890
hc-eth-type : 8891
l2ep-eth-type : 8893
ha-uptime-diff-margin: 300
vcluster2 : disable
vcluster-id : 1
override : disable
priority : 128
slave-switch-standby: disable
minimum-worker-threshold: 1
monitor :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-slave-force-reset: enable
pingserver-flip-timeout: 60
vdom : "root"
```

11. Power off the FortiGate.

To configure the second FortiGate (host name FGT_ha_2)

1. Power on the FortiGate.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal, enter a name for the connection, and select **OK**.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select **OK**.
5. Select the following port settings and select **OK**.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

6. Press **Enter** to connect to the FortiGate CLI.
The FortiGate CLI login prompt appears. If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.
7. Type `admin` and press **Enter** twice.
8. Register and apply licenses to the FortiGate.
9. Change the host name for this FortiGate.

```
config system global
    set hostname FGT_ha_2
end
```

10. Configure HA settings.

```
config system ha
    set mode a-a
    set group-name example2.com
    set password HA_pass_2
end
```

The FortiGate negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

11. Display the HA configuration (optional).

```
get system ha
group-id : 0
group-name : example2.com
mode : a-a
password : *
```

```

hbdev : "port3" 50 "port4" 50
session-sync-dev :
route-ttl : 10
route-wait : 0
route-hold : 10
sync-config : enable
encryption : disable
authentication : disable
hb-interval : 2
hb-lost-threshold : 20
hello-holddown : 20
arps : 5
arps-interval : 8
session-pickup : disable
update-all-session-timer: disable
session-sync-daemon-number: 1
link-failed-signal : disable
uninterruptible-upgrade: enable
ha-mgmt-status : disable
ha-eth-type : 8890
hc-eth-type : 8891
l2ep-eth-type : 8893
ha-uptime-diff-margin: 300
vcluster2 : disable
vcluster-id : 1
override : disable
priority : 128
schedule : round-robin
monitor :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-slave-force-reset: enable
pingserver-flip-timeout: 60
vdom : "root"
schedule : round-robin

```

12. Power off the FortiGate.

To connect the cluster to the network

1. Connect the port1 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internet.
2. Connect the port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To connect to the cluster CLI and switch the cluster to transparent mode

1. Determine which cluster unit is the primary unit.

- Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
- Enter the command `get system status`.
- If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step 2.
- If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit. Connect to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode.

2. Change to transparent mode.

```
config system settings
  set opmode transparent
  set manageip 192.168.20.3/24
  set gateway 192.168.20.1
end
```

The cluster switches to transparent Mode, and your administration session is disconnected.

You can now connect to the cluster CLI using SSH to connect to the cluster internal interface using the management IP address (192.168.20.3).

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Determine which cluster unit is the primary unit.

- Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
- Enter the command `get system status`.
- If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step ["Active-active HA cluster in transparent mode" on page 1412](#).
- If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit. Connect the null-modem cable to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode and you should review your HA configuration.

2. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
HA Health Status: OK
Model: FortiGate-XXXX
Mode: HA A-P
Group: 0
Debug: 0
Cluster Uptime: 7 days 00:30:26
.
```

.

.

You can use this command to confirm that the cluster is healthy and operating normally, some information about the cluster configuration, and information about how long the cluster has been operating. Information not shown in this example includes how the primary unit was selected, configuration synchronization status, usage stats for each cluster unit, heartbeat status, and the relative priorities of the cluster units.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGates are not functioning as a cluster. See [Troubleshooting HA clusters on page 1458](#) to troubleshoot the cluster.

To add a password for the admin administrative account

1. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <psswr>
end
```

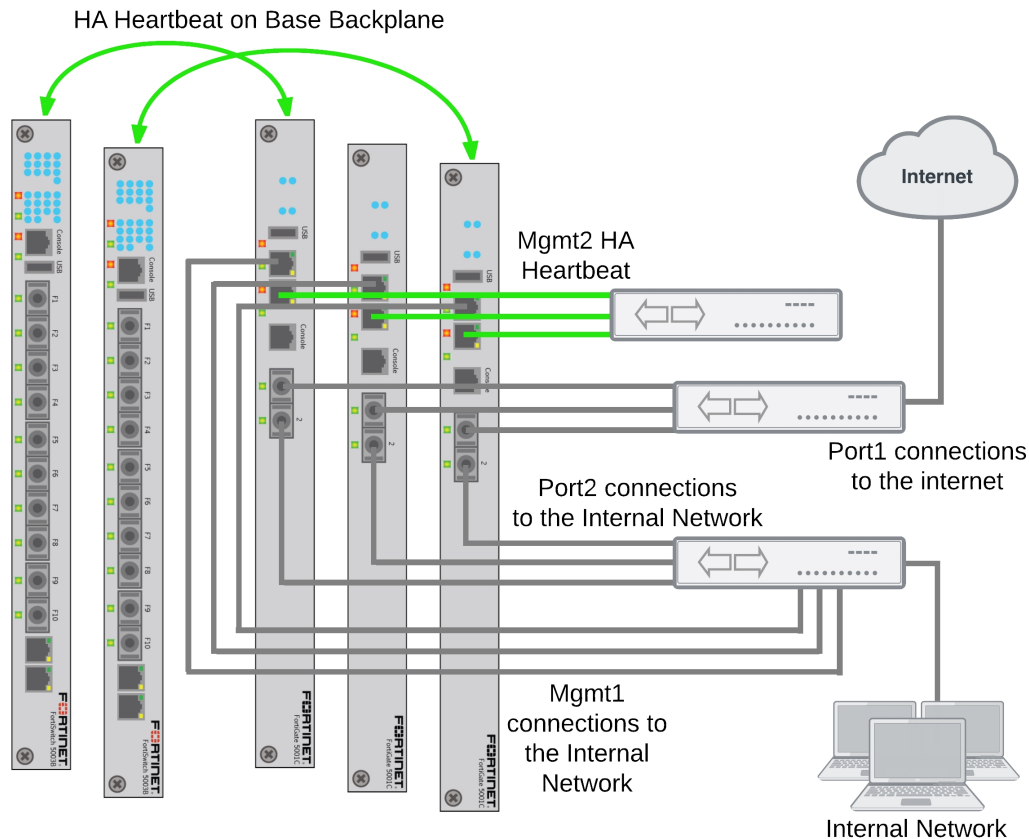

FortiGate-5000 active-active HA cluster with FortiClient licenses

This section describes how to configure an HA cluster of three FortiGate-5001D units that connect an internal network to the internet. The FortiGate-5001D units each have a FortiClient license installed on them to support FortiClient profiles.

Normally it is recommended that you add FortiClient licenses to the FortiGates before setting up the cluster. This example; however, describes how to apply FortiClient licenses to the FortiGates in an operating cluster.

Example network topology

The following diagram shows an HA cluster consisting of three FortiGate-5001D cluster units (host names slot-3, slot-4, and slot-5) installed in a FortiGate-5000 series chassis with two FortiController-5003B units for heartbeat communication between the cluster units. The cluster applies security features including FortiClient profiles to data traffic passing through it.

The cluster is managed from the internal network using the FortiGate-5001D mgmt1 interfaces configured as HA reserved management interfaces. Using these reserved management interfaces the overall cluster can be managed and cluster units can be managed individually. Individual management access to each cluster unit makes some operations, such as installing FortiClient licenses, easier and also allows you to view status of each cluster unit.

The reserved management interface of each cluster unit has a different IP address and retains its own MAC address. The cluster does not change the reserved management interface MAC address.

Example network topology

By default base1 and base2 are used for heartbeat communication between the FortiGates. To use the base1 and base2 interfaces for the HA heartbeat, the example describes how to display the backplane interfaces on the GUI before turning on HA.

This example also includes using the mgmt2 interface for heartbeat communication for additional heartbeat redundancy.

To connect the cluster

1. Connect the FortiGate-5001D port1 interfaces to a switch and connect that switch to the internet.
2. Connect the FortiGate-5001D port2 interfaces to a switch and connect that switch to the internal network.
3. Connect the FortiGate-5001D mgmt1 interfaces to a switch that connects to the engineering network.
4. Connect the FortiGate-5001D mgmt2 interfaces to a switch for heartbeat communication between them.

Configuring the FortiGate-5000 active-active cluster - GUI

These procedures assume you are starting with three FortiGate-5001D boards and two FortiSwitch-5003B boards installed in a compatible FortiGate-5000 series chassis. The FortiSwitch-5003B boards are in chassis slots 1 and 2 and the FortiGate-5001D boards are in chassis slots 3, 4, and 5 and the chassis is powered on. All devices are in their factory default configuration. No configuration changes to the FortiSwitch-5003B boards are required.

To configure the FortiGate-5001D units

1. From the internal network, log into the GUI of the FortiGate-5001D unit in chassis slot 3 by connecting to the mgmt1 interface.

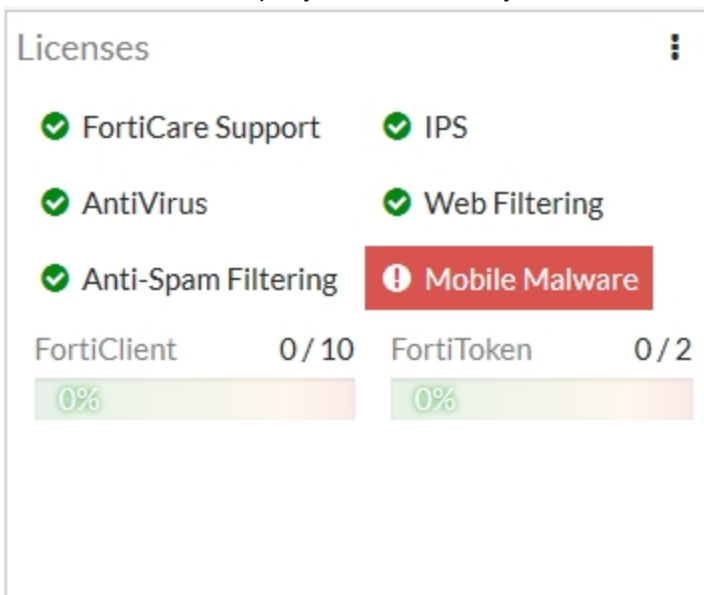

By default the mgmt1 interface of each FortiGate-5001D unit has the same IP address. To log into each FortiGate-5001D unit separately you could either disconnect the mgmt1 interfaces of the units that you don't want to log into or change the mgmt1 interface IP addresses for each unit by connecting to each unit's CLI from their console port.

2. Register and apply licenses to the FortiGate before configuring it for HA operation. This includes licensing for **FortiCare Support**, **IPS**, **AntiVirus**, **Web Filtering**, **Mobile Malware**, **FortiCloud**, and additional **virtual domains** (VDOMs). All FortiGates in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs. **FortiToken** licenses can be added at any time because they are synchronized to all cluster members. FortiClient licenses will be added in a following step.

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license.

You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed, third-party certificates are synchronized to the backup FortiGate.

3. Click on the System Information dashboard widget and select **Configure settings** in **System > Settings**.
4. Enter a new Host Name for this FortiGate, for example:

New Name	5001D-Slot-3
-----------------	--------------

5. Connect to the CLI and enter the following command to display backplane interfaces on the GUI:

```
config system global
  set show-backplane-intf enable
end
```

6. Set the Administrative Status of the base1 and base 2 interfaces to **Up**.

You can do this from the GUI by going to **Network > Interfaces**, editing each interface and setting **Administrative Status** to **Up**.

You can also do this from the CLI using the following command:

```
config system interface
  edit base1
    set status up
  next
  edit base2
    set status up
end
```

7. Go to **Network > Interfaces** and configure the IP address of the mgmt1 interface.

Because mgmt1 will become the reserved management interface for the cluster unit each FortiGate-5001D should have a different mgmt1 interface IP address. Give the mgmt1 interface an address that is valid for the internal network. Once HA with the reserved Management interface is enabled the IP address of the mgmt1 interface can be on the same subnet as the port2 interface (which will also be connected to the Internal network).

After the FortiGate is operating in HA mode the mgmt1 interface will retain its original MAC address instead of being assigned a virtual MAC address.

8. Go to **System > HA** and change the following settings:

Set the **Mode** to **Active-Active**.

Select **Reserve Management Port for Cluster Member** and select **mgmt1**.

Set the group name and password:

Group Name	example3.com
Password	HA_pass_3

Set the Heartbeat interface configuration to use base1, base2 and mgmt2 for heartbeat communication. Set the priority of each heartbeat interface to 50:

Heartbeat Interface		
	Enable	Priority
base1	Select	50
base2	Select	50
mgmt2	Select	50

9. Select **OK**.

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate-5001D interfaces change to the following virtual MAC addresses:

- base1 interface virtual MAC: 00-09-0f-09-00-00
- base2 interface virtual MAC: 00-09-0f-09-00-01
- fabric1 interface virtual MAC: 00-09-0f-09-00-02
- fabric2 interface virtual MAC: 00-09-0f-09-00-03
- fabric3 interface virtual MAC: 00-09-0f-09-00-04
- fabric4 interface virtual MAC: 00-09-0f-09-00-05
- fabric5 interface virtual MAC: 00-09-0f-09-00-06
- mgmt1 keeps its original MAC address
- mgmt2 interface virtual MAC: 00-09-0f-09-00-08
- port1 interface virtual MAC: 00-09-0f-09-00-09
- port2 interface virtual MAC: 00-09-0f-09-00-0a

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic base1
.
.
.
Current_HWaddr 00:09:0f:09:00:00
Permanent_HWaddr 00:09:0f:71:0a:dc
.
.
.
```

9. Repeat these steps for the FortiGate-5001D units in chassis slots 4 and 5, with the following differences. Set the mgmt1 interface IP address of each FortiGate-5001D unit to a different IP address.

Set the FortiGate-5001D unit in chassis slot 4 host name to:

New Name	5001D-Slot-4
-----------------	--------------

Set the FortiGate-5001D unit in chassis slot 5 host name to:

New Name	5001D-Slot-5
-----------------	--------------

As you configure each FortiGate, they will negotiate and join the cluster.

To view cluster status

As you add units to the cluster you can log into the GUI of one of the cluster units to view the status of the cluster. The status displays will show each unit as it is added to the cluster.

1. Log into the primary unit or any cluster unit and view the system dashboard.
The HA Status dashboard widget displays how long the cluster has been operating (Uptime) and the time since the last failover occurred (State Changed) You can hover over the State Changed time to see the event that caused the state change You can also click on the HA Status dashboard widget to configure HA settings or to get a listing of the most recent HA events recorded by the cluster.
2. Go to **System > HA** to view the cluster members list.
The list shows both cluster units, their host names, their roles in the cluster, and their device priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster

See [Troubleshooting HA clusters on page 1458](#).

To manage each cluster unit

Because you have configured a reserved management interface, you can manage each cluster unit separately by connecting to the IP address you configured for each unit's mgmt1 interface. You can view the status of each cluster unit and make changes to each unit's configuration. For example, as described below, each cluster unit must have its own FortiClient license. You can use the reserved management IP addresses to connect to each cluster unit to install the FortiClient license for that unit.

Usually you would make configuration changes by connecting to the primary unit and changing its configuration. The cluster then synchronizes the configuration changes to all cluster units. If you connect to individual cluster units and change their configuration, those configuration changes are also synchronized to each cluster unit. The exception to this is configuration objects that are not synchronized, such as the host name, FortiClient license and so on.

You can also manage each cluster unit by logging into the primary unit CLI and using the following command to connect to other cluster units:

```
execute ha manage <cluster-index>
```

To add basic configuration settings to the cluster

Use the following steps to configure the cluster.

1. Log into the cluster GUI.
You can log into the primary unit or any one of the cluster units using the appropriate mgmt1 IP address.
2. Go to **System > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.
6. Go to **Network > Interfaces** and edit the **port1** interface. Set this interface IP address to the address required to connect to the interface to the internet.
7. Edit the port2 interface and set its IP to an IP address for the internal network.

To add a FortiClient license to each cluster unit

Normally you would add FortiClient licenses to the FortiGates before forming the cluster. However, you can use the following steps to add FortiClient licenses to an operating cluster.

Contact your reseller to purchase FortiClient licenses for your cluster units. Each cluster unit must have its own FortiClient license.

When you receive the license keys you can visit the [Fortinet Support](#) website and add a FortiClient license key to each licensed FortiGate. Then, as long as the cluster can connect to the internet the license keys are downloaded from the FortiGuard network to all of the FortiGates in the cluster.

You can also use the following steps to manually add the license keys to your cluster units from the GUI. Your cluster must be connected to the internet.

1. Log into the GUI of each cluster unit using its reserved management interface IP address.
2. Go to the **License Information** dashboard widget and beside FortiClient select **Enter License**.
3. Enter the license key and select **OK**.
4. Confirm that the license has been installed and the correct number of FortiClients are licensed.
5. Repeat for all of the cluster units.

You can also use the following command to add the license key from the CLI:

```
execute FortiClient-NAC update-registration-license <license-number>
```

You can connect to the CLIs of each cluster unit using their reserved management IP address.

You can also log into the primary unit CLI and use the `execute ha manage` command to connect to each cluster unit CLI.

Configuring the FortiGate-5000 active-active cluster - CLI

These procedures assume you are starting with three FortiGate-5001D boards and two FortiSwitch-5003B boards installed in a compatible FortiGate-5000 series chassis. The FortiSwitch-5003B boards are in chassis slots 1 and 2 and the FortiGate-5001D boards are in chassis slots 3, 4, and 5 and the chassis is powered on. All devices are in their factory default configuration. No configuration changes to the FortiSwitch-5003B boards are required.

To configure the FortiGate-5005FA2 units

1. From the internal network, log into the CLI of the FortiGate-5001D unit in chassis slot 3 by connecting to the mgmt1 interface.

By default the mgmt1 interface of each FortiGate-5001D unit has the same IP address. To log into each FortiGate-5001D unit separately you could either disconnect the mgmt1 interfaces of the units that you don't want to log into or change the mgmt1 interface IP addresses for each unit by connecting to each unit's CLI from their console port.

You can also use a console connection.

2. Register and apply licenses to the FortiGate.
3. Change the host name for this FortiGate. For example:

```
config system global
  set hostname 5001D-Slot-3
end
```

4. Enter the following command to display backplane interfaces on the GUI:

```
config system global
  set show-backplane-intf enable
end
```

5. Set the Administrative Status of the base1 and base 2 interfaces to **Up**.

```
config system interface
  edit base1
    set status up
  next
  edit base2
    set status up
end
```

6. Add an IP address to the mgmt1 interface.

```
config system interface
  edit mgmt1
    set ip 172.20.120.110/24
    set allowaccess http https ssl ping
  end
```

Because mgmt1 will become the reserved management interface for the cluster unit each FortiGate-5001D should have a different mgmt1 interface IP address. Give the mgmt1 interface an address that is valid for the internal network. Once HA with the reserved Management interface is enabled the IP address of the mgmt1 interface can be on the same subnet as the port2 interface (which will also be connected to the Internal network).

7. Configure HA settings.

```
config system ha
  set mode a-a
  set ha-mgmt-status enable
  set ha-mgmt-interface mgmt1
  set group-name example3.com
  set password HA_pass_3
  set hbdev base1 50 base2 50 mgmt2 50
end
```

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate-5001D interfaces change to the following virtual MAC addresses:

- base1 interface virtual MAC: 00-09-0f-09-00-00
- base2 interface virtual MAC: 00-09-0f-09-00-01
- fabric1 interface virtual MAC: 00-09-0f-09-00-02
- fabric2 interface virtual MAC: 00-09-0f-09-00-03
- fabric3 interface virtual MAC: 00-09-0f-09-00-04
- fabric4 interface virtual MAC: 00-09-0f-09-00-05
- fabric5 interface virtual MAC: 00-09-0f-09-00-06
- mgmt1 keeps its original MAC address
- mgmt2 interface virtual MAC: 00-09-0f-09-00-08
- port1 interface virtual MAC: 00-09-0f-09-00-09
- port2 interface virtual MAC: 00-09-0f-09-00-0a

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic base1
.
.
.
Current_HWaddr 00:09:0f:09:00:00
Permanent_HWaddr 00:09:0f:71:0a:dc
.
.
.
```

7. Repeat these steps for the FortiGate-5001D units in chassis slots 4 and 5, with the following differences. Set the mgmt1 interface IP address of each FortiGate-5001D unit to a different IP address.

Set the FortiGate-5001D unit in chassis slot 4 host name to:

```
config system global
    set hostname 5001D-Slot-4
end
```

Set the FortiGate-5001D unit in chassis slot 5 host name to:

```
config system global
    set hostname 5001D-Slot-5
end
```

As you configure each FortiGate, they will negotiate and join the cluster.

To view cluster status

As you add units to the cluster you can log into the CLI of one of the cluster units using its reserved management interface to view the status of the cluster. The status will show each unit as it is added to the cluster.

For example, the following command output shows the status of the cluster when all three cluster units have been added:

```
get system ha status
HA Health Status: OK
Model: FortiGate-XXXX
Mode: HA A-P
Group: 0
Debug: 0
Cluster Uptime: 7 days 00:30:26
.
.
.
Slave : 5001d-slot4      , FG-5KD3914800284, operating cluster index = 2
Master: 5001d-slot5     , FG-5KD3914800353, operating cluster index = 0
Slave : 5001d-slot3     , FG-5KD3914800344, operating cluster index = 1
```

You can use this command to confirm that the cluster is healthy and operating normally, some information about the cluster configuration, and information about how long the cluster has been operating. Information not shown in this example includes how the primary unit was selected, configuration synchronization status, usage stats for each cluster unit, heartbeat status, and the relative priorities of the cluster units.

To troubleshoot the cluster

See [Troubleshooting HA clusters on page 1458](#).

To manage each cluster unit

Because you have configured a reserved management interface, you can manage each cluster unit separately by connecting to the IP address you configured for each unit's mgmt1 interface. You can view the status of each cluster unit and make changes to each unit's configuration. For example, as described below, each cluster unit must have its own FortiClient license. You can use the reserved management IP addresses to connect to each cluster unit to install the FortiClient license for that unit.

Usually you would make configuration changes by connecting to the primary unit and changing its configuration. The cluster then synchronizes the configuration changes to all cluster units. If you connect to individual cluster units and change their configuration, those configuration changes are also synchronized to each cluster unit. The exception to this is configuration objects that are not synchronized, such as the host name, FortiClient license and so on.

You can also manage each cluster unit by logging into the primary unit CLI and using the following command to connect to other cluster units:

```
execute ha manage <cluster-index>
```

To add a password for the admin administrative account

1. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <psswr>
  end
```

To add basic configuration settings to the cluster

Use the following steps to configure the cluster.

1. Log into the cluster CLI.

You can log into the primary unit or any one of the cluster units using the appropriate mgmt1 IP address.

2. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <psswr>
  end
```

3. Set the port1 interface IP address to the address required to connect to the interface to the internet.

```
config system interface
  edit port1
    set ip 10.10.10.10/24
  end
```

4. Set the port2 interface IP address to the address required to connect to the interface to the internal network.

```
config system interface
edit port2
set ip 172.20.120.12/24
end
```

To add a FortiClient license to each cluster unit

Normally you would add FortiClient licenses to the FortiGates before forming the cluster. However, you can use the following steps to add FortiClient licenses to an operating cluster.

Contact your reseller to purchase FortiClient licenses for your cluster units. Each cluster unit must have its own FortiClient license.

When you receive the license keys you can visit the [Fortinet Support](#) website and add a FortiClient license key to each licensed FortiGate. Then, as long as the cluster can connect to the internet the license keys are downloaded from the FortiGuard network to all of the FortiGates in the cluster.

You can also use the following steps to manually add the license keys to your cluster units from the CLI. Your cluster must be connected to the internet.

1. Log into the CLI of each cluster unit using its reserved management interface IP address.
2. Enter the following command to the unit's serial number:

```
get system status
```

3. Enter the following command to add the license key for that serial number:

```
execute FortiClient-NAC update-registration-license <license-key>
```

4. Confirm that the license has been installed and the correct number of FortiClients are licensed.

```
execute forticlient info
Maximum FortiClient connections: unlimited.
Licensed connections: 114
    NAC: 114
    WANOPT: 0
    Test: 0
Other connections:
    IPsec: 0
    SSLVPN: 0
```

5. Repeat for all of the cluster units.

You can also log into the primary unit CLI and use the `execute ha manage` command to connect to each cluster unit CLI.

Replacing a failed cluster unit

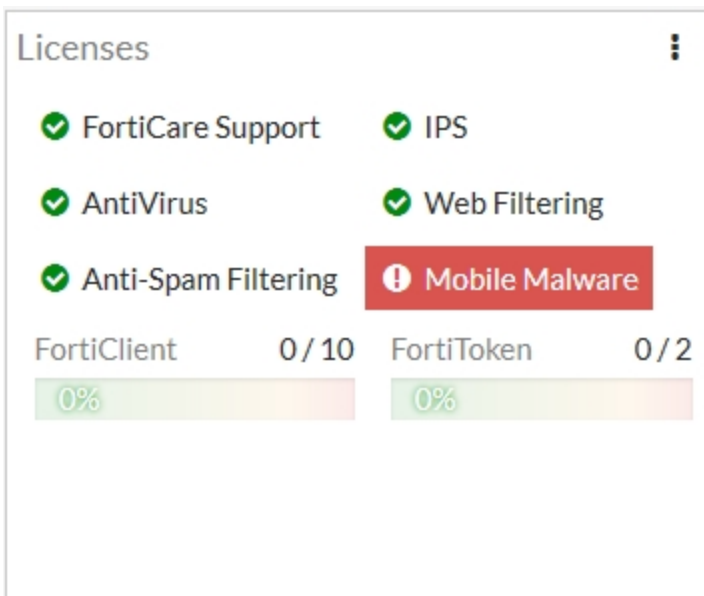

This procedure describes how to remove a failed cluster unit from a cluster and add a new one to replace it. You can also use this procedure to remove a failed unit from a cluster, repair it and add it back to the cluster.

Replacing a failed does not interrupt the operation of the cluster unless you have to change how the cluster is connected to the network to accommodate the replacement unit.

You can use this procedure to replace more than one cluster unit.

To replace a failed cluster unit

1. Disconnect the failed unit from the cluster and the network.
If you maintain other connections between the network and the still functioning cluster unit or units and between remaining cluster units network traffic will continue to be processed.
2. Repair the failed cluster unit, or obtain a replacement unit with the exact same hardware configuration as the failed cluster unit.
3. Install the same firmware build on the repaired or replacement unit as is running on the cluster.
4. Register and apply licenses to the FortiGate. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS). All of the FortiGates in a cluster must have the same level of licensing.

5. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
We recommend that you add FortiToken licenses and FortiTokens to the primary unit after the cluster has formed.
6. Configure the repaired or replacement unit for HA operation with the same HA configuration as the cluster.
7. If the cluster is running in transparent mode, change the operating mode of the repaired or replacement unit to transparent mode.
8. Connect the repaired or replacement cluster unit to the cluster.
For an example see [How to set up FGCP clustering \(recommended steps\) on page 1412](#).
9. Power on the repaired or replacement cluster unit.
When the unit starts it negotiates to join the cluster. After it joins the cluster, the cluster synchronizes the repaired or replacement unit configuration with the configuration of the primary unit.

You can add a repaired or replacement unit to a functioning cluster at any time. The repaired or replacement cluster unit must:

- Have the same hardware configuration as the cluster units. Including the same hard disk configuration and the same AMC cards installed in the same slots.
- Have the same firmware build as the cluster.

- Be set to the same operating mode (NAT or transparent) as the cluster.
- Be operating in single VDOM mode.

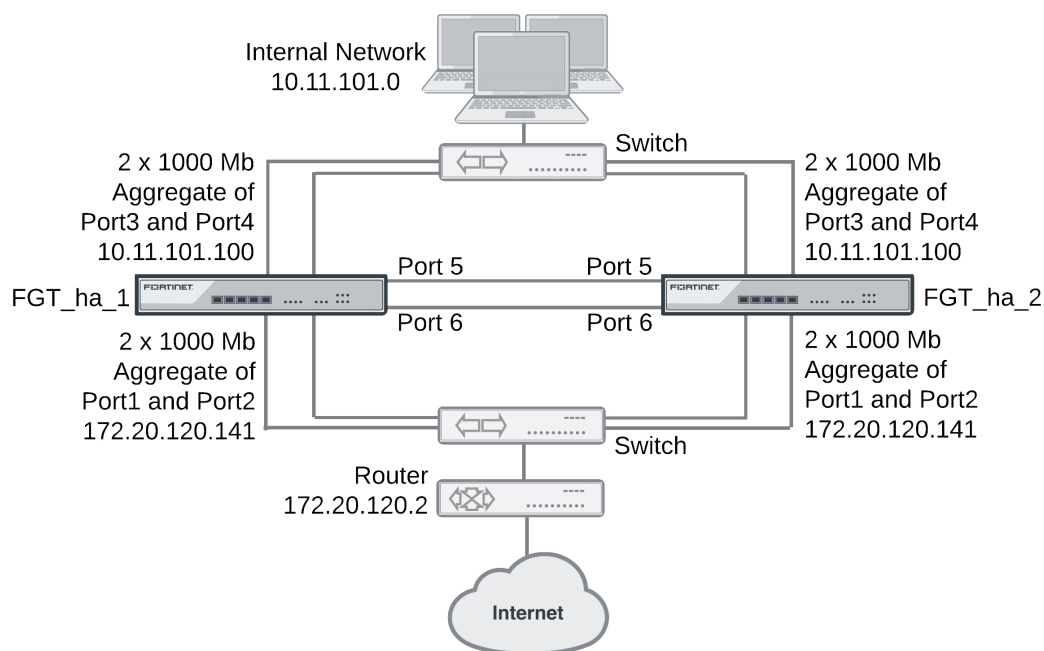

FGCP HA with 802.3ad aggregated interfaces

On FortiGate models that support it you can use 802.3ad link aggregation to combine two or more interfaces into a single aggregated interface. 802.3ad Link Aggregation and its management protocol, Link Aggregation Control Protocol (LACP) are a method for combining multiple physical links into a single logical link. This increases both potential throughput and network resiliency. Using LACP, traffic is distributed among the physical interfaces in the link, potentially resulting in increased performance.

This example describes how to configure an HA cluster consisting of two FortiGates with two aggregated 1000 Mb connections to the internet using port1 and port2 and two aggregated 1000 Mb connections to the internal network using port3 and port4. The aggregated interfaces are also configured as HA monitored interfaces.

Each of the aggregate links connects to a different switch. Each switch is configured for link aggregation (2x1000Mb).

Example cluster with aggregate interfaces

HA interface monitoring, link failover, and 802.3ad aggregation

When monitoring the aggregated interface, HA interface monitoring treats the aggregated link as a single interface and does not monitor the individual physical interfaces in the link. HA interface monitoring registers the link to have failed only if all the physical interfaces in the link have failed. If only some of the physical interfaces in the link fail or become disconnected, HA considers the link to be operating normally.

HA MAC addresses and 802.3ad aggregation

If a configuration uses the Link Aggregate Control Protocol (LACP) (either passive or active), LACP is negotiated over all of the interfaces in any link. For a standalone FortiGate, the FortiGate LACP implementation uses the MAC address of the first interface in the link to uniquely identify that link. For example, a link consisting of port1 and port2 interfaces would have the MAC address of port1.

In an HA cluster, HA changes the MAC addresses of the cluster interfaces to virtual MAC addresses. An aggregate interface in a cluster acquires the virtual MAC address that would have been acquired by the first interface in the aggregate.

Link aggregation, HA failover performance, and HA mode

To operate an active-active or active-passive cluster with aggregated interfaces and for best performance of a cluster with aggregated interfaces, the switches used to connect the cluster unit aggregated interfaces together should support configuring multiple Link Aggregation (LAG) groups.

For example, the cluster shown above should be configured into two LAG groups on the external switch: one for the port1 and port2 aggregated interface of FGT_ha_1 and a second one for the port1 and port2 aggregate interface of FGT_ha_2. You should also be able to do the same on the internal switch for the port3 and port4 aggregated interfaces of each cluster unit.

As a result, the subordinate unit aggregated interfaces would participate in LACP negotiation while the cluster is operating. In an active-active mode cluster, packets could be redirected to the subordinate unit interfaces. As well, in active-active or active-passive mode, after a failover the subordinate unit can become a primary unit without having to perform LACP negotiation before it can process traffic. Performing LACP negotiation causes a minor failover delay.

However if you cannot configure multiple LAG groups on the switches, due to the primary and subordinate unit interfaces having the same MAC address, the switch will put all of the interfaces into the same LAG group which would disrupt the functioning of the cluster. To prevent this from happening, you must change the FortiGate aggregated interface configuration to prevent subordinate units from participating in LACP negotiation.

For example, use the following command to prevent subordinate units from participating in LACP negotiation with an aggregate interface named Port1_Port2:

```
config system interface
  edit Port1_Port2
    set lacp-ha-slave disable
  end
```

As a result of this setting, subordinate unit aggregated interfaces cannot accept packets. This means that you cannot operate the cluster in active-active mode because in active-active mode the subordinate units must be able to receive and process packets. Also, failover may take longer because after a failover the subordinate unit has to perform LACP negotiation before being able to process network traffic.

Also, it may also be necessary to configure the switch to use Passive or even Static mode for LACP to prevent the switch from sending packets to the subordinate unit interfaces, which won't be able to process them.

Finally, in some cases depending on the LACP configuration of the switches, you may experience delayed failover if the FortiGate LACP configuration is not compatible with the switch LACP configuration. For example, in some cases setting the FortiGate LACP mode to static reduces the failover delay because the FortiGate does not perform LACP negotiation. However there is a potential problem with this configuration because static LACP does not send periodic LAC Protocol Data Unit (LACPDU) packets to test the connections. So a non-physical failure (for example, if a device is not responding because its too busy) may not be detected and packets could be lost or delayed.

General configuration steps

The section includes GUI and CLI procedures. These procedures assume that the FortiGates are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1. Apply licenses to the FortiGates to become the cluster.
2. Configure the FortiGates for HA operation.
 - Change each unit's host name.
 - Configure HA.
2. Connect the cluster to the network.
3. View cluster status.
4. Add basic configuration settings and configure the aggregated interfaces.
 - Add a password for the admin administrative account.
 - Add the aggregated interfaces.
 - Disable `lacp-ha-slave` so that the subordinate unit does not send LACP packets.
 - Add a default route.

You could also configure aggregated interfaces in each FortiGate before the units form a cluster.

5. Configure HA port monitoring for the aggregated interfaces.

Configuring active-passive HA cluster that includes aggregated interfaces - GUI

These procedures assume you are starting with two FortiGates with factory default settings.

To configure the FortiGates for HA operation

1. Register and apply licenses to the FortiGate.

2. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
3. Enter a new Host Name for this FortiGate.

New Name	FGT_ha_1
-----------------	----------

4. Select **OK**.
5. Go to **System > HA** and change the following settings.

Mode	Active-Passive	
Group Name	example5.com	
Password	HA_pass_5	
Heartbeat Interface		
	Enable	Priority
port5	Select	50
port6	Select	50

Since port3 and port4 will be used for an aggregated interface, you must change the HA heartbeat configuration to not use those interfaces.

6. Select **OK**.

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11

- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7. Power off the first FortiGate.
8. Repeat these steps for the second FortiGate.

Set the second FortiGate host name to:

New Name	FGT_ha_2

To connect the cluster to the network

1. Connect the port1 and port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internet. Configure the switch so that the port1 and port2 of FGT_ha_1 make up an aggregated interface and port1 and port2 of FGT_ha_2 make up a second aggregated interface.
2. Connect the port3 and port4 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network. Configure the switch so that the port3 and port4 of FGT_ha_1 make up an aggregated interface and port3 and port4 of FGT_ha_2 make up another aggregated interface.
3. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete, the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.

The HA Status dashboard widget displays how long the cluster has been operating (Uptime) and the time since the last failover occurred (State Changed) You can hover over the State Changed time to see the event that caused the state change You can also click on the HA Status dashboard widget to configure HA settings or to get a listing of the most recent HA events recorded by the cluster.

2. Go to **System > HA** to view the cluster members list.

The list shows both cluster units, their host names, their roles in the cluster, and their device priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

See [Troubleshooting HA clusters on page 1458](#) to troubleshoot the cluster.

To add basic configuration settings and the aggregate interfaces

Use the following steps to add a few basic configuration settings.

1. Log into the cluster GUI.
2. Go to **System > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.
6. Go to **Network > Static Routes** and temporarily delete the default route.
You cannot add an interface to a aggregated interface if any settings (such as the default route) are configured for it.
7. Go to **Network > Interfaces** and select **Create New > Interface** to add the aggregate interface to connect to the internet.
8. Set **Type** to **802.3ad Aggregate** and configure the aggregate interface to be connected to the internet:

Name	Port1_Port2
Interface Members	port1, port2
IP/Network Mask	172.20.120.141/24

9. Select **OK**.
10. Select **Create New > Interface** to add the aggregate interface to connect to the internal network.
11. Set **Type** to **802.3ad Aggregate** and configure the aggregate interface to be connected to the internet:

Name	Port3_Port4
Interface Members	port3, port4
IP/Netmask	10.11.101.100/24
Administrative Access	HTTPS, PING, SSH

12. Select **OK**.

The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

13. Connect to the CLI and enter the following command to disable sending LACP packets from the subordinate unit:

```
config system interface
  edit Port1_Port2
    set lacp-ha-slave disable
  next
  edit Port3_Port4
    set lacp-ha-slave disable
end
```

14. Go to **Network > Static Routes**.

15. Add the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	Port1_Port2
Distance	10

16. Select **OK**.

To configure HA port monitoring for the aggregate interfaces

1. Go to **System > HA**.
2. In the cluster members list, edit the primary unit.
3. Configure the following port monitoring for the aggregate interfaces:

Port Monitor	
Port1_Port2	Select
Port3_Port4	Select

4. Select **OK**.

Configuring active-passive HA cluster that includes aggregate interfaces - CLI

These procedures assume you are starting with two FortiGates with factory default settings.

To configure the FortiGates for HA operation

1. Register and apply licenses to the FortiGate. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS). All of the FortiGates in a cluster must have the same level of licensing.
2. Install any third-party certificates on the FortiGate.
3. Change the host name for this FortiGate:

```
config system global
    set hostname FGT_ha_1
end
```

4. Configure HA settings.

```
config system ha
    set mode a-p
    set group-name example5.com
    set password HA_pass_5
    set hbdev port5 50 port6 50
end
```

Since port3 and port4 will be used for an aggregated interface, you must change the HA heartbeat configuration.

The FortiGate negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06

- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4. Repeat these steps for the other FortiGate.

Set the other FortiGate host name to:

```
config system global
    set hostname FGT_ha_2
end
```

To connect the cluster to the network

1. Connect the port1 and port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internet. Configure the switch so that the port1 and port2 of FGT_ha_1 make up an aggregated interface and port1 and port2 of FGT_ha_2 make up another aggregated interface.
2. Connect the port3 and port4 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network. Configure the switch so that the port3 and port4 of FGT_ha_1 make up an interfaced and port3 and port4 of FGT_ha_2 make up another aggregated interface.

3. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. Enter `get system status` to verify the HA status of the cluster unit that you logged into. Look for the following information in the command output.

Current HA mode: a-a, master	The cluster units are operating as a cluster and you have connected to the primary unit.
Current HA mode: a-a, backup	The cluster units are operating as a cluster and you have connected to a subordinate unit.
Current HA mode: standalone	The cluster unit is not operating in HA mode

3. Enter the following command to view the status of the cluster:

```
get system ha status
HA Health Status: OK
Model: FortiGate-XXXX
Mode: HA A-P
Group: 0
Debug: 0
Cluster Uptime: 7 days 00:30:26
.
.
.
```

You can use this command to confirm that the cluster is healthy and operating normally, some information about the cluster configuration, and information about how long the cluster has been operating. Information not shown in this example includes how the primary unit was selected, configuration synchronization status, usage stats for each cluster unit, heartbeat status, and the relative priorities of the cluster units.

To troubleshoot the cluster configuration

See [Troubleshooting HA clusters on page 1458](#) to troubleshoot the cluster.

To add basic configuration settings and the aggregate interfaces

Use the following steps to add a few basic configuration settings and the aggregate interfaces.

1. Add a password for the admin administrative account.

```

config system admin
  edit admin
    set password <psswr>
  end

```

2. Temporarily delete the default route.

You cannot add an interface to an aggregate interface if any settings (such as the default route) are configured for it. In this example the index of the default route is 1.

```

config router static
  delete 1
end

```

3. Add the aggregate interfaces:

```

config system interface
  edit Port1_Port2
    set type aggregate
    set lacp-ha-slave disable
    set member port1 port2
    set ip 172.20.120.141/24
    set vdom root
  next
  edit Port3_Port4
    set type aggregate
    set lacp-ha-slave disable
    set member port3 port4
    set ip 10.11.101.100/24
    set vdom root
  end
end

```

The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10

- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

4. Add the default route.

```
config router static
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set gateway 172.20.120.2
    set device Port1_Port2
  end
```

To configure HA port monitoring for the aggregate interfaces

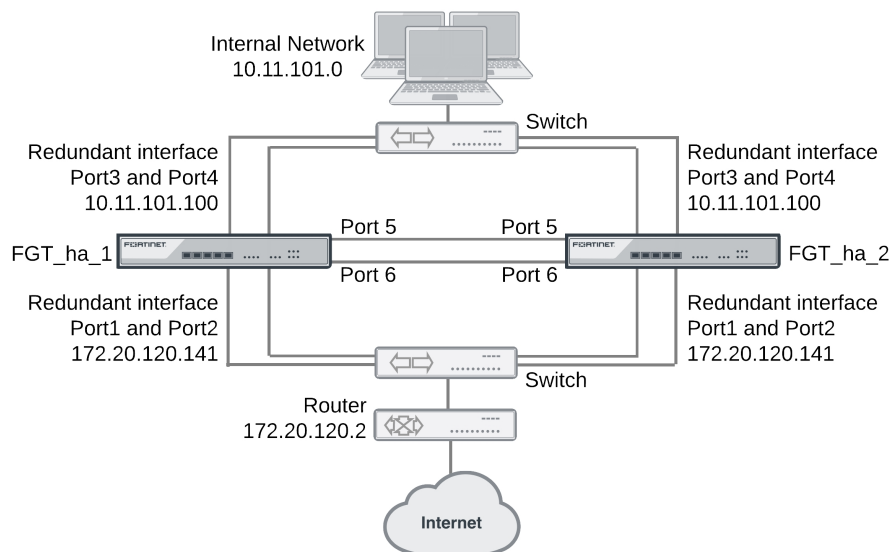

1. Configure HA port monitoring for the aggregate interfaces.

```
config system ha
  set monitor Port1_Port2 Port3_Port4
end
```

Example HA and redundant interfaces

On FortiGate models that support it you can combine two or more interfaces into a single redundant interface. A redundant interface consists of two or more physical interfaces. Traffic is processed by the first physical interface in the redundant interface. If that physical interface fails, traffic fails over to the next physical interface. Redundant interfaces don't have the benefit of improved performance that aggregate interfaces can have, but they do provide failover if a physical interface fails or is disconnected.

Example cluster with a redundant interfaces

This example describes how to configure an HA cluster consisting of two FortiGates with a redundant interface connection to the internet and to an internal network. The connection to the internet uses port1 and port2. The connection to the internal network uses port3 and port4. The HA heartbeat uses port5 and port6.

The redundant interfaces are also configured as HA monitored interfaces.

HA interface monitoring, link failover, and redundant interfaces

HA interface monitoring monitors the redundant interface as a single interface and does not monitor the individual physical interfaces in the redundant interface. HA interface monitoring registers the redundant interface to have failed only if all the physical interfaces in the redundant interface have failed. If only some of the physical interfaces in the redundant interface fail or become disconnected, HA considers the redundant interface to be operating normally.

HA MAC addresses and redundant interfaces

For a standalone FortiGate a redundant interface has the MAC address of the first physical interface added to the redundant interface configuration. A redundant interface consisting of port1 and port2 would have the MAC address of port1.

In an HA cluster, HA changes the MAC addresses of the cluster interfaces to virtual MAC addresses. A redundant interface in a cluster acquires the virtual MAC address that would have been acquired by the first physical interface added to the redundant interface configuration.

Connecting multiple redundant interfaces to one switch while operating in active-passive HA mode

HA assigns the same virtual MAC addresses to the subordinate unit interfaces as are assigned to the corresponding primary unit interfaces. Consider a cluster of two FortiGates operating in active-passive mode with a redundant interface consisting of port1 and port2. You can connect multiple redundant interfaces to the same switch if you configure the switch so that it defines multiple separate redundant interfaces and puts the redundant interfaces of each cluster unit into separate redundant interfaces. In this configuration, each cluster unit forms a separate redundant interface with the switch.

However, if the switch is configured with a single four-port redundant interface configuration, because the same MAC addresses are being used by both cluster units, the switch adds all four interfaces (port1 and port2 from the primary unit and port1 and port2 from the subordinate unit) to the same redundant interface.

To avoid unpredictable results, when you connect a switch to multiple redundant interfaces in an active-passive cluster you should configure separate redundant interfaces on the switch; one for each cluster unit.

Connecting multiple redundant interfaces to one switch while operating in active-active HA mode

In an active-active cluster, all cluster units send and receive packets. To operate a cluster with redundant interfaces in active-active mode, with multiple redundant interfaces connected to the same switch, you must separate the redundant interfaces of each cluster unit into different redundant interfaces on the connecting switch.

General configuration steps

The section includes GUI and CLI procedures. These procedures assume that the FortiGates are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1. Apply licenses to the FortiGates to become the cluster.
2. Configure the FortiGates for HA operation.

- Change each unit's host name.
 - Configure HA.
2. Connect the cluster to the network.
 3. View cluster status.
 4. Add basic configuration settings and configure the redundant interfaces.
 - Add a password for the admin administrative account.
 - Add the redundant interfaces.
 - Add a default route.

You could also configure redundant interfaces in each FortiGate before they form a cluster.

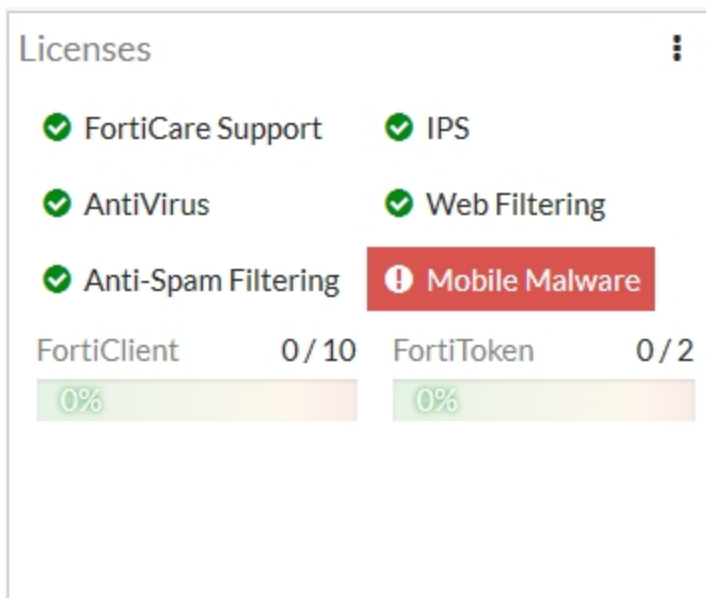

5. Configure HA port monitoring for the redundant interfaces.

Configuring active-passive HA cluster that includes redundant interfaces - GUI

These procedures assume you are starting with two FortiGates with factory default settings.

To configure the FortiGates for HA operation

1. Register and apply licenses to the FortiGate.

2. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
3. Enter a new Host Name for this FortiGate.

New Name	FGT_ha_1
-----------------	----------

4. Select **OK**.
5. Go to **System > HA** and change the following settings.

Mode	Active-Passive
-------------	----------------

Group Name	example6.com	
Password	HA_pass_6	
Heartbeat Interface		
	Enable	Priority
port5	Select	50
port6	Select	50

Since port3 and port4 will be used for a redundant interface, you must change the HA heartbeat configuration.

6. Select OK.

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following

command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7. Power off the first FortiGate.
8. Repeat these steps for the second FortiGate.
Set the second FortiGate host name to:

New Name	FGT_ha_2
----------	----------

To connect the cluster to the network

1. Connect the port1 and port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internet. Configure the switch so that the port1 and port2 of FGT_ha_1 make up a redundant interface and port1 and port2 of FGT_ha_2 make up another redundant interface.
2. Connect the port3 and port4 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network. Configure the switch so that the port3 and port4 of FGT_ha_1 make up a redundant interface and port3 and port4 of FGT_ha_2 make up another redundant interface.
3. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.
The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.
The HA Status dashboard widget displays how long the cluster has been operating (Uptime) and the time since the last failover occurred (State Changed). You can hover over the State Changed time to see the event that caused the state change. You can also click on the HA Status dashboard widget to configure HA settings or to get a listing of the most recent HA events recorded by the cluster.
2. Go to **System > HA** to view the cluster members list.
The list shows both cluster units, their host names, their roles in the cluster, and their device priorities.

You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

See [Troubleshooting HA clusters on page 1458](#).

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings.

1. Log into the cluster GUI.
2. Go to **System > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.
6. Go to **Network > Static Routes** and temporarily delete the default route.
You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.
7. Go to **Network > Interfaces** and select **Create New > Interface** to add the redundant interface to connect to the internet.
8. Set **Type** to **Redundant Interface** and configure the redundant interface to be connected to the internet:

Name	Port1_Port2
Physical Interface Members	port1, port2
IP/Netmask	172.20.120.141/24

9. Select **OK**.
10. Select **Create New** to add the redundant interface to connect to the internal network.
11. Set **Type** to **Redundant Interface** and configure the redundant interface to be connected to the internet:

Name	Port3_Port4
Physical Interface Members	port3, port4
IP/Netmask	10.11.101.100/24
Administrative Access	HTTPS, PING, SSH

12. Select **OK**.
The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:
 - port1 interface virtual MAC: 00-09-0f-09-00-00
 - port10 interface virtual MAC: 00-09-0f-09-00-01
 - port11 interface virtual MAC: 00-09-0f-09-00-02

- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

13. Go to **Router > Static > Static Routes**.

14. Add the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	Port1_Port2
Distance	10

15. Select **OK**.

To configure HA port monitoring for the redundant interfaces

1. Go to **System > HA**.
2. In the cluster members list, edit the primary unit.
3. Configure the following port monitoring for the redundant interfaces:

	Port Monitor
Port1_Port2	Select
Port3_Port4	Select

4. Select **OK**.

Configuring active-passive HA cluster that includes redundant interfaces - CLI

These procedures assume you are starting with two FortiGates with factory default settings.

To configure the FortiGates for HA operation

1. Register and apply licenses to the FortiGate. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS). All of the FortiGates in a cluster must have the same level of licensing.
2. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
We recommend that you add FortiToken licenses and FortiTokens to the primary unit after the cluster has formed.
3. Change the host name for this FortiGate:

```
config system global
    set hostname FGT_ha_1
end
```

4. Configure HA settings.

```
config system ha
    set mode a-p
    set group-name example6.com
    set password HA_pass_6
    set hbdev port5 50 port6 50
end
```

Since port3 and port4 will be used for a redundant interface, you must change the HA heartbeat configuration.

The FortiGate negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4. Repeat these steps for the other FortiGate.

Set the other FortiGate host name to:

```
config system global
    set hostname FGT_ha_2
end
```

To connect the cluster to the network

1. Connect the port1 and port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internet. Configure the switch so that the port1 and port2 of FGT_ha_1 make up a redundant interface and port1 and port2 of FGT_ha_2 make up another redundant interface.
2. Connect the port3 and port4 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network. Configure the switch so that the port3 and port4 of FGT_ha_1 make up a redundant interface and port3 and port4 of FGT_ha_2 make up another redundant interface.
3. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.
The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. Enter `get system status` to verify the HA status of the cluster unit that you logged into. Look for the following information in the command output.

Current HA mode: a-a, master	The cluster units are operating as a cluster and you have connected to the primary unit.
Current HA mode: a-a, backup	The cluster units are operating as a cluster and you have connected to a subordinate unit.
Current HA mode: standalone	The cluster unit is not operating in HA mode

3. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
HA Health Status: OK
Model: FortiGate-XXXX
Mode: HA A-P
Group: 0
Debug: 0
Cluster Uptime: 7 days 00:30:26
.
.
.
```

You can use this command to confirm that the cluster is healthy and operating normally, some information about the cluster configuration, and information about how long the cluster has been operating. Information not shown in this example includes how the primary unit was selected, configuration synchronization status, usage stats for each cluster unit, heartbeat status, and the relative priorities of the cluster units.

To troubleshoot the cluster configuration

See [Troubleshooting HA clusters on page 1458](#).

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings and the redundant interfaces.

1. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <psswr>
  end
```

2. Temporarily delete the default route.

You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it. In this example the index of the default route is 1.

```
config router static
  delete 1
end
```

3. Add the redundant interfaces:

```
config system interface
  edit Port1_Port2
    set type redundant
    set member port1 port2
```

```

        set ip 172.20.120.141/24
        set vdom root
    next
    edit Port3_Port4
        set type redundant
        set member port3 port4
        set ip 10.11.101.100/24
        set vdom root
    end

```

The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

4. Add the default route.

```

config router static
    edit 1
        set dst 0.0.0.0 0.0.0.0
        set gateway 172.20.120.2
        set device Port1_Port2
    end

```

To configure HA port monitoring for the redundant interfaces

1. Configure HA port monitoring for the redundant interfaces.

```

config system ha
    set monitor Port1_Port2 Port3_Port4
end

```

Troubleshooting HA clusters

This section describes some HA clustering troubleshooting techniques.

Ignoring hardware revisions

Many FortiGate platforms have gone through multiple hardware versions and in some cases the hardware changes prevent cluster formation. If you run into this problem you can use the following command on each FortiGate to cause the cluster to ignore different hardware versions:

```
execute ha ignore-hardware-revision enable
```

This command is only available on FortiGates that have had multiple hardware revisions.

By default the command is set to prevent cluster formation between FortiGates with different hardware revisions. You can enter the following command to view its status:

```
execute ha ignore-hardware-revision status
```

Usually the incompatibility is caused by different hardware versions having different hard disks and enabling this command disables the hard disks in each FortiGate. As a result of disabling hard disks the cluster will not support logging to the hard disk or WAN Optimization.

If the FortiGates do have compatible hardware versions or if you want to run a FortiGate in standalone mode you can enter the following command to disable ignoring the hardware revision and enable the hard disks:

```
execute ha ignore-hardware-revision disable
```

Affected models include but are not limited to:

- FortiGate-100D
- FortiGate-300C
- FortiGate-600C
- FortiGate-800C
- FortiGate-80C and FortiWiFi-80C
- FortiGate-60C

It's possible that a cluster will not form because the disk partition sizes of the cluster units are different. You can use the `diagnose sys ha checksum test | grep storage` command to check the disk storage checksum of each cluster unit. If the checksums are different then visit the [Fortinet Support](#) website for help in setting up compatible storage partitions.

Before you set up a cluster

Before you set up a cluster ask yourself the following questions about the FortiGates that you are planning to use to create a cluster.

1. Do all the FortiGates have the same hardware configuration? Including the same hard disk configuration?
2. Do all of the FortiGates have the same FortiGuard, FortiCloud, FortiClient, VDOM and FortiOS Carrier licensing?
3. Do all the FortiGates have the same firmware build?
4. Are all the FortiGates set to the same operating mode (NAT or transparent)?
5. Are all the FortiGates operating in single VDOM mode?
6. If the FortiGates are operating in multiple VDOM mode do they all have the same VDOM configuration?

In some cases you may be able to form a cluster if different FortiGates have different firmware builds, different VDOM configurations, and are in different operating modes. However, if you encounter problems they may be resolved by installing the same firmware build on each unit, and give them the same VDOM configuration and operating mode. If the FortiGates in the cluster have different licenses, the cluster will form but it will operate with the lowest licensing level.

Troubleshooting the initial cluster configuration

This section describes how to check a cluster when it first starts up to make sure that it is configured and operating correctly. This section assumes you have already configured your HA cluster.

To verify that a cluster can process traffic and react to a failure

1. Add a basic security policy configuration and send network traffic through the cluster to confirm connectivity.
For example, if the cluster is installed between the internet and an internal network, set up a basic internal to external security policy that accepts all traffic. Then from a PC on the internal network, browse to a website on the internet or ping a server on the internet to confirm connectivity.
2. From your management PC, set ping to continuously ping the cluster, and then start a large download, or in some other way establish ongoing traffic through the cluster.
3. While traffic is going through the cluster, disconnect the power from one of the cluster units.
You could also shut down or restart a cluster unit.
Traffic should continue with minimal interruption.
4. Start up the cluster unit that you disconnected.
The unit should re-join the cluster with little or no affect on traffic.
5. Disconnect a cable from one of the HA heartbeat interfaces.
The cluster should keep functioning, using the other HA heartbeat interface.
6. If you have port monitoring enabled, disconnect a network cable from a monitored interface.
Traffic should continue with minimal interruption.

To verify the cluster configuration from the GUI

Use these steps if a cluster is formed just to verify its status and configuration.

1. Log into the cluster GUI.
2. Check the system dashboard to verify that the System Information widget displays all of the cluster units.
3. Check the Unit Operation widget graphic to verify that the correct cluster unit interfaces are connected.
4. Go to **System > HA** or from the System Information dashboard widget select **HA Status > Configure** and verify that all of the cluster units are displayed on the HA Cluster list.
5. From the cluster members list, edit the primary unit (master) and verify the cluster configuration is as expected.

To troubleshoot the cluster configuration from the GUI

Use these steps if the FortiGates don't successfully form a cluster:

1. Connect to each cluster unit GUI and verify that the HA configurations are the same. The HA configurations of all of the cluster units must be identical. Even though the HA configuration is very simple you can easily make a small

mistake that prevents a FortiGate from joining a cluster.

2. If the configurations are the same, try re-entering the HA **Password** on each cluster unit in case you made an error typing the password when configuring one of the cluster units.
3. Check that the correct interfaces of each cluster unit are connected.
Check the cables and interface LEDs.

Use the Unit Operation dashboard widget, system network interface list, or cluster members list to verify that each interface that should be connected actually is connected.

If the link is down re-verify the physical connection. Try replacing network cables or switches as required.

To verify the cluster configuration from the CLI

Use these steps if a cluster is formed just to verify its status and configuration.

1. Log into each cluster unit CLI.
You can use the console connection if you need to avoid the problem of units having the same IP address.
2. Enter the command `get system status`.
Look for the following information in the command output.

Current HA mode: a-a, master	The cluster units are operating as a cluster and you have connected to the primary unit.
Current HA mode: a-a, backup	The cluster units are operating as a cluster and you have connected to a subordinate unit.
Current HA mode: standalone	The cluster unit is not operating in HA mode

3. Verify that the `get system ha status` command shows that the cluster health is OK and shows that all of the cluster units have joined the cluster.
4. Enter the `get system ha` command to verify that the HA configuration is correct and the same for each cluster unit.

To troubleshoot the cluster configuration from the CLI

Try these steps if the FortiGates don't successfully form a cluster:

1. Try using the following command to re-enter the cluster password on each cluster unit in case you made an error typing the password when configuring one of the cluster units.

```
config system ha
  set password <password>
end
```

2. Check that the correct interfaces of each cluster unit are connected.
Check the cables and interface LEDs.

Use `get hardware nic <interface_name>` command to confirm that each interface is connected. If the interface is connected the command output should contain a `Link: up` entry similar to the following:

```

get hardware nic port1
.
.
.
Link: up
.
.
.

```

If the link is down, re-verify the physical connection. Try replacing network cables or switches as required.

More troubleshooting information

Much of the information in this HA guide can be useful for troubleshooting HA clusters. Here are some links to sections with more information.

- If sessions are lost after a failover you may need to change route-ttl to keep synchronized routes active longer. See [Synchronizing kernel routing tables on page 1546](#)
- To control which cluster unit becomes the primary unit, you can change the device priority and enable override. See [Controlling primary unit selection using device priority and override on page 1395](#)
- Changes made to a cluster can be lost if override is enabled. See [Configuration changes can be lost if override is enabled on page 1396](#)
- When override is enabled, after a failover traffic may be disrupted if the primary unit rejoins the cluster before the session tables are synchronized or for other reasons such as if the primary unit is configured for DHCP or PPPoE. See [Delaying how quickly the primary unit rejoins the cluster when override is enabled on page 1397](#).
- In some cases, age differences among cluster units result in the wrong cluster unit becoming the primary unit. For example, if a cluster unit set to a high priority reboots, that unit will have a lower age than other cluster units. You can resolve this problem by resetting the age of one or more cluster units. See [Primary unit selection and age on page 1387](#) You can also adjust how sensitive the cluster is to age differences. This can be useful if large age differences cause problems. See [Cluster age difference margin \(grace period\) on page 1388](#) and [Changing the cluster age difference margin on page 1388](#).
- If one of the cluster units needs to be serviced or removed from the cluster for other reasons, you can do so without affecting the operation of the cluster. See [Disconnecting a cluster unit from a cluster on page 1518](#)
- The GUI and CLI will not allow you to configure HA if you have enabled FGSP HA. See [FortiGate Session Life Support Protocol \(FGSP\) on page 1606](#).
- The GUI and CLI will not allow you to configure HA if one or more FortiGate interfaces is configured as a PPTP or L2TP client.
- The FGCP is compatible with DHCP and PPPoE but care should be taken when configuring a cluster that includes a FortiGate interface configured to get its IP address with DHCP or PPPoE. Fortinet recommends that you turn on DHCP or PPPoE addressing for an interface after the cluster has been configured. See [FortiGate HA compatibility with DHCP and PPPoE on page 1397](#).
- Some third-party network equipment may prevent HA heartbeat communication, resulting in a failure of the cluster or the creation of a split brain scenario. For example, some switches use packets with the same Ethertype as HA heartbeat packets use for internal functions and when used for HA heartbeat communication the switch generates CRC errors and the packets are not forwarded. See [Heartbeat packet Ethernets on page 1527](#).
- Very busy clusters may not be able to send HA heartbeat packets quickly enough, also resulting in a split brain scenario. You may be able to resolve this problem by modifying HA heartbeat timing. See [Modifying heartbeat timing on page 1528](#).

- Very busy clusters may suffer performance reductions if session pickup is enabled. If possible you can disable this feature to improve performance. If you require session pickup for your cluster, several options are available for improving session pickup performance. See [Improving session synchronization performance on page 1](#).
- If it takes longer than expected for a cluster to failover you can try changing how the primary unit sends gratuitous ARP packets. See [Changing how the primary unit sends gratuitous ARP packets after a failover on page 1531](#).
- You can also improve failover times by configuring the cluster for sub-second failover. See [Sub-second failover on page 1555](#) and [Failover performance on page 1566](#).
- When you first put a FortiGate in HA mode you may lose connectivity to the unit. This occurs because HA changes the MAC addresses of all FortiGate interfaces, including the one that you are connecting to. The cluster MAC addresses also change if you change some HA settings such as the cluster group ID. The connection will be restored in a short time as your network and PC updates to the new MAC address. To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.
- Since HA changes all cluster unit MAC addresses, if your network uses MAC address filtering you may have to make configuration changes to account for the HA MAC addresses.
- A network may experience packet loss when two FortiGate HA clusters have been deployed in the same broadcast domain. Deploying two HA clusters in the same broadcast domain can result in packet loss because of MAC address conflicts. The packet loss can be diagnosed by pinging from one cluster to the other or by pinging both of the clusters from a device within the broadcast domain. You can resolve the MAC address conflict by changing the HA Group ID configuration of the two clusters. The HA Group ID is sometimes also called the Cluster ID. See [Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain on page 1535](#).
- The cluster CLI displays `slave is not in sync` messages if there is a synchronization problem between the primary unit and one or more subordinate units. See [How to diagnose HA out of sync messages on page 1543](#).
- If you have configured dynamic routing and the new primary unit takes too long to update its routing table after a failover you can configure graceful restart and also optimize how routing updates are synchronized. See [Configuring graceful restart for dynamic routing failover on page 1547](#) and [Synchronizing kernel routing tables on page 1546](#).
- Some switches may not be able to detect that the primary unit has become a subordinate unit and will keep sending packets to the former primary unit. This can occur after a link failover if the switch does not detect the failure and does not clear its MAC forwarding table. See [Updating MAC forwarding tables when a link failover occurs on page 1553](#).
- If a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails you can enable remote link failover to maintain communication. See [Remote link failover on page 1556](#).
- If you find that some cluster units are not running the same firmware build you can reinstall the correct firmware build on the cluster to upgrade all cluster units to the same firmware build. See [Synchronizing the firmware build running on a new cluster unit on page 1508](#).

Virtual clusters

This chapter describes virtual clustering, a variation of the FGCP for FortiGates with multiple VDOMs. Virtual clustering includes can operate in active-passive or active-active HA mode for clusters of up to four FortiGates. Active-passive virtual clustering includes VDOM partitioning that to distribute traffic for different VDOMs between the primary and backup FortiGates.

Virtual clustering overview

Virtual clustering is an extension of the FGCP that provides failover protection between two instances of one or more VDOMs operating on two FortiGates in a virtual cluster.

A standard virtual cluster consists of up to four FortiGates operating in active-passive or active-active HA mode with multiple VDOMS enabled.

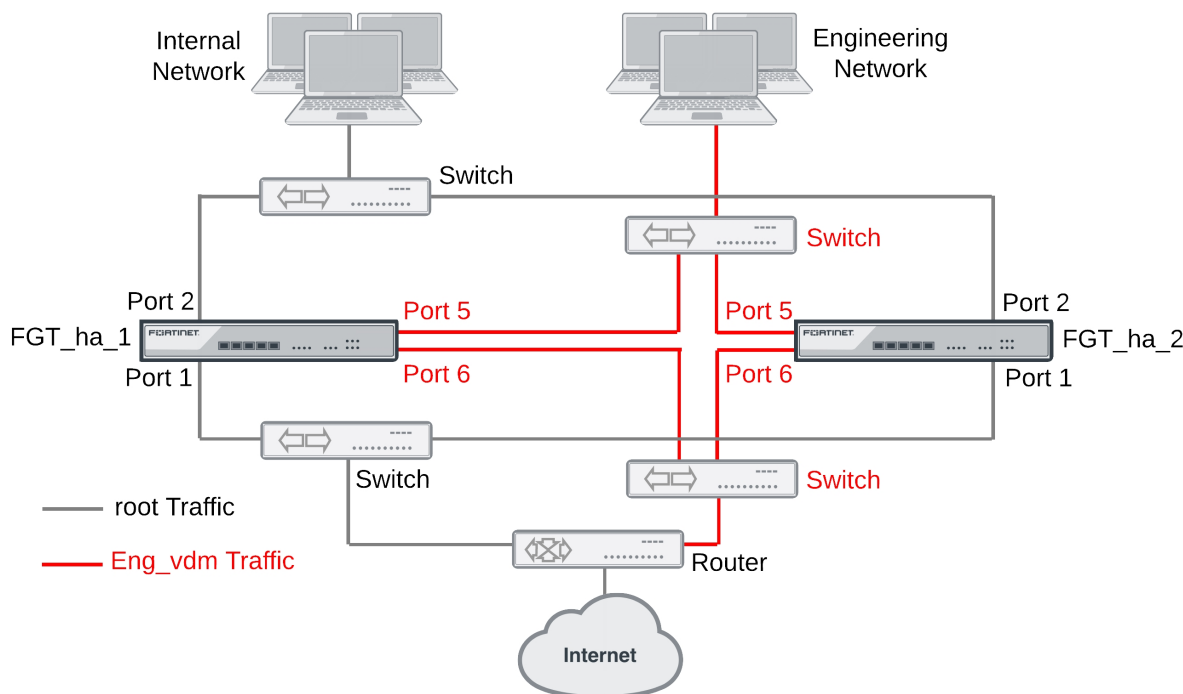

Active-passive virtual clustering uses VDOM partitioning to send traffic for some VDOMs to the primary FortiGate and traffic for other VDOMs to the backup FortiGate. Traffic distribution between both FortiGates can potentially improve throughput. If a failure occurs and only one FortiGate continues to operate, all traffic fails over to that FortiGate, similar to normal HA. If the failed FortiGates restart, the configured traffic distribution is restored.

Active-active virtual clustering operates just the same as standard FGCP active-active HA, distributing traffic to all of the FortiGates in the cluster using FGCP load balancing.

In an active-passive virtual cluster of two FortiGates, the primary and backup FortiGates share traffic processing according to the VDOM partitioning configuration. If you add a third or fourth FortiGate, the primary and first backup FortiGate process all traffic and the other one or two FortiGates operate in standby mode. If the primary or first backup FortiGate fails, one of the other FortiGates becomes the new primary or backup FortiGate and begins processing traffic.

The figure below shows an example virtual cluster configuration consisting of two FortiGates. The virtual cluster has two VDOMs, root and Eng_vdm.

Example virtual cluster

The root VDOM includes the port1 and port2 interfaces. The Eng_vdm VDOM includes the port5 and port6 interfaces. The port3 and port4 interfaces (not shown in the diagram) are the HA heartbeat interfaces.

If you don't want active-passive virtual clustering to distribute traffic between FortiGates, you can configure VDOM partitioning to send traffic for all VDOMs to the primary unit. The result is the same as standard active-passive FCGP HA, all traffic is processed by the primary FortiGate.

Separation of VDOM traffic

Virtual clustering creates a cluster between instances of each VDOM on the two FortiGates in the virtual cluster. All traffic to and from a given VDOM is sent to one of the FortiGates where it stays within its VDOM and is only processed by that VDOM. One FortiGate is the primary FortiGate for each VDOM and one FortiGate is the backup FortiGate for each VDOM. The primary FortiGate processes all traffic for its VDOMs. The backup FortiGate processes all traffic for its VDOMs.

If your cluster has a VLAN that is part of a different VDOM than the physical interface that the VLAN has been added to, then you must configure VDOM partitioning to keep traffic for both of these VDOMs on the same FortiGate.

Virtual clustering and heartbeat interfaces

The HA heartbeat provides the same HA services in a virtual clustering configuration as in a standard HA configuration. One set of HA heartbeat interfaces provides HA heartbeat services for all of the VDOMs in the cluster. You do not have to add a heartbeat interface for each VDOM.

Virtual clustering and load balancing

There are two ways to configure load balancing for virtual clustering. The first is to set the HA mode to active-active. The second is to configure VDOM partitioning. For virtual clustering, setting the HA Mode to active-active has the same result as active-active HA for a cluster without virtual domains. The primary FortiGate receives all sessions and load balances them among the cluster units according to the load balancing schedule. All cluster units process traffic for all virtual domains.

In an active-passive virtual clustering configuration, you can configure a form of load balancing by using VDOM partitioning to distribute traffic between the primary and backup FortiGates. While a cluster is operating, you can change the VDOM partitioning configuration to change the distribution of traffic between the cluster units. For example, if you have two VDOMs with high traffic volume you can set up VDOM partitioning so that different FortiGates process the traffic for each high-volume VDOM. If over time traffic patterns change you can dynamically re-adjust VDOM partitioning to optimize traffic throughput. VDOM partitioning can be changed at any time with only minor traffic disruptions.

Configuring virtual clustering

Configuring virtual clustering is the same as configuring standard FCGP HA with the addition of VDOM partitioning. Using VDOM partitioning you can control the distribution of VDOMs, and the traffic they process, between the FortiGates in the cluster.

VDOM partitioning can be thought of in two parts. First there is configuring the distribution of VDOMs between two virtual clusters. By default, all VDOMs are in virtual cluster 1 and virtual cluster 1 is associated with the primary FortiGate. In this configuration, the primary FortiGate processes all traffic. If you want traffic to be processed by the backup FortiGate, you need to enable virtual cluster 2, move some of the VDOMs to it, and associate virtual cluster 2 with the backup FortiGate.

Since there are only two virtual clusters, even in a virtual clustering configuration of three or four FortiGates only two of the FortiGates process traffic. The third and fourth FortiGates operate in standby mode and process traffic after a failover.

By default all VDOMs are in virtual cluster 1 and the primary FortiGate processes all traffic.

You associate a virtual cluster with a FortiGate using priorities. The FortiGate with the highest device priority is associated with virtual cluster 1. To associate a FortiGate with virtual cluster 2 you must enable virtual cluster 2 and set the virtual cluster 2 device priority. The FortiGate with the highest virtual cluster 2 device priority processes traffic for the VDOMs added to virtual cluster 2. (Reminder: device priorities are not synchronized.)

If both FortiGates have the same device priority, virtual cluster 1 is associated with the primary FortiGate. If both FortiGates have the same virtual cluster 2 device priority, virtual cluster 2 is associated with the primary FortiGate.

Virtual clustering and the override setting

Enabling virtual cluster 2 also turns on the HA override setting. Enabling override is required for virtual clustering to function as configured. Enabling override causes the cluster to negotiate every time a failure occurs. If override is not enabled, the cluster will not negotiate after all failures. While more frequent negotiation may cause more minor traffic disruptions, with virtual clustering its more important to negotiate after any failure to make sure the correct traffic flows are maintained.

Example virtual clustering configuration

For example, consider a configuration that includes four VDOMs: root, Engineering, Marketing, and Finance. You can use the following configuration to send root and Engineering traffic to the primary FortiGate and Marketing and Finance traffic to the backup FortiGate.

First, on the primary FortiGate:

- Set the device priority to 200
- Enable virtual cluster 2 (vcluster2)
- Set the virtual cluster 2 device priority (secondary-vcluster) to 50
- Add the Marketing and Finance VDOMs to virtual cluster 2 (secondary-vcluster)

When you enable multiple VDOMs, virtual cluster 2 is enabled by default. Even so the command to enable virtual cluster 2 is included in this example in case for some reason it has been disabled. Enabling virtual cluster 2 also enables override.

```
config global
  config system ha
    set mode a-p
    set group-name mygroup
    set password <password>
    set priority 200
    set vcluster2 enable
    config secondary-vcluster
      set vdom Marketing Finance
      set priority 50
    end
  end
end
```

Then on the backup FortiGate:

- Set the device priority to 50 (lower than the primary FortiGate)
- Enable virtual cluster 2 (vcluster2)
- Set the virtual cluster 2 device priority (secondary-vcluster) to 200 (higher than the primary FortiGate).

```
config global
  config system ha
    set mode a-p
    set group-name mygroup
    set password <password>
    set priority 50
    set vcluster2 enable
    config secondary-vcluster
      set priority 200
    end
  end
end
```

Since the primary FortiGate has the highest device priority, the primary unit processes all traffic for the VDOMs in virtual cluster 1. Since the backup FortiGate has the highest virtual cluster 2 device priority, the backup FortiGate processes all traffic for the VDOMs in virtual cluster 2. The primary FortiGate configuration adds the VDOMs to virtual cluster 2. All you have to configure on the backup FortiGate for virtual cluster 2 is the virtual cluster 2 (or secondary-vcluster) device priority.

Adding a third FortiGate to the virtual cluster

You can add a third FortiGate to the virtual cluster and configure it so that if the primary FortiGate fails, the third FortiGate becomes the new primary FortiGate or if the backup FortiGate fails, the third FortiGate becomes the new backup FortiGate.

On the third FortiGate:

- Set the device priority to 150 (lower than the primary FortiGate but higher than the backup FortiGate)
- Enable virtual cluster 2 (vcluster2)
- Set the virtual cluster 2 device priority (secondary-vcluster) to 100 (higher than the primary FortiGate but lower than the backup FortiGate)

```
config global
  config system ha
    set mode a-p
    set group-name mygroup
    set password <password>
    set priority 150
    set vcluster2 enable
    config secondary-vcluster
      set priority 100
    end
  end
end
```

Adding a fourth FortiGate to the virtual cluster

You can add a fourth FortiGate to the virtual cluster and configure it so that:

- If the primary FortiGate fails, the third FortiGate becomes the new primary FortiGate, the backup FortiGate continues to operate as the backup FortiGate.
- If the backup FortiGate fails, the fourth FortiGate becomes the new backup FortiGate.
- If both the primary and backup FortiGates fail, the third FortiGate becomes the primary FortiGate and the fourth FortiGate becomes the backup FortiGate.

On the fourth FortiGate:

- Set the device priority to 100 (lower than the primary and third FortiGate but higher than the backup FortiGate)
- Enable virtual cluster 2 (vcluster2)
- Set the virtual cluster 2 device priority (secondary-vcluster) to 150 (higher than the primary FortiGate and the third FortiGate but lower than the backup FortiGate)

```
config global
  config system ha
    set mode a-p
    set group-name mygroup
    set password <password>
    set priority 100
```

```
set vcluster2 enable
config secondary-vcluster
    set priority 150
end
end
```

Virtual clustering with four FortiGates recommended configuration

As described in the previous sections, here is a recommended device priority configuration for a virtual cluster consisting of four FortiGates. Other configurations are also supported depending on how you want the virtual cluster to respond to a failure.

FortiGate	Device Priority	Virtual Cluster 2 Device Priority
Primary	200	50
Backup	50	100
Third	150	200
Fourth	100	150

Virtual clustering GUI configuration

From the GUI, you configure virtual clustering from the Global menu by going to **System > HA** setting the **Mode** to **Active-Passive** and enabling **VDOM Partitioning**.

Example primary FortiGate virtual clustering configuration

Mode	Active-Passive ▼
Device priority ⓘ	200

Virtual clustering configuration examples

See the following cookbook recipe for a virtual clustering configuration example. This example shows how to set up a virtual cluster of two FortiGates and then how to add a third and fourth FortiGate to the virtual cluster configuration.

- FGCP virtual clustering with two FortiGates
- FGCP virtual clustering with two FortiGates

Inter-VDOM links in a virtual clustering configuration

In a virtual domain configuration you can use inter-VDOM links to route traffic between two virtual domains operating in a single FortiGate without using physical interfaces. Adding an inter-VDOM link has the affect of adding two interfaces to the FortiGate and routing traffic between the virtual domains using the inter-VDOM link interfaces.

In a virtual clustering configuration inter-VDOM links can only be made between virtual domains that are in the same virtual cluster. So, if you are planning on configuring inter-VDOM links in a virtual clustering configuration, you should make sure the virtual domains that you want to link are in the same virtual cluster.

For example, the following tables show an example virtual clustering configuration where each virtual cluster contains four virtual domains. In this configuration you can configure inter-VDOM links between root and vdom_1 and between vdom_2 and vdom_3. But, you cannot configure inter-VDOM links between root and vdom_2 or between vdom_1 and vdom_3 (and so on).

Hostname		
Virtual Domains	FortiGate_A	FortiGate_B
root	Priority	Priority
	200	100
vdom_1	Role	Role
	Primary	Subordinate

Hostname		
Virtual Domains	FortiGate_A	FortiGate_B
vdom_2	Priority	Priority
	100	200
vdom_3	Role	Role
	Subordinate	Primary

Configuring inter-VDOM links in a virtual clustering configuration

Configuring inter-VDOM links in a virtual clustering configuration is very similar to configuring inter-VDOM links for a standalone FortiGate. The main difference the `config system vdom-link` command includes the `vcluster` keyword. The default setting for `vcluster` is `vcluster1`. So you only have to use the `vcluster` keyword if you are added an inter-VDOM link to virtual cluster 2.

To add an inter-VDOM link to virtual cluster 1

This procedure describes how to create an inter-VDOM link to virtual cluster 1 that results in a link between the root and vdom_1 virtual domains.

Inter-VDOM links are also called internal point-to-point interfaces.

1. Add an inter-VDOM link called `vc1link`.

```
config global
  config system vdom-link
    edit vc1link
  end
```

Adding the inter-VDOM link also adds two interfaces. In this example, these interfaces are called `vc1link0` and `vc1link1`. These interfaces appear in all CLI and GUI interface lists. These interfaces can only be added to virtual domains in virtual cluster 1.

2. Bind the `vc1link0` interface to the root virtual domain and bind the `vc1link1` interface to the `vdom_1` virtual domain.

```
config system interface
  edit vc1link0
    set vdom root
  next
  edit vc1link1
    set vdom vdom_1
  end
```

To add an inter-VDOM link to virtual cluster 2

This procedure describes how to create an inter-VDOM link to virtual cluster 2 that results in a link between the `vdom_2` and `vdom_3` virtual domains.

1. Add an inter-VDOM link called `vc2link`.

```
config global
  config system vdom-link
    edit vc2link
      set vcluster vcluster2
    end
```

Adding the inter-VDOM link also adds two interfaces. In this example, these interfaces are called `vc2link0` and `vc2link1`. These interfaces appear in all CLI and GUI interface lists. These interfaces can only be added to virtual domains in virtual cluster 2.

2. Bind the `vc2link0` interface to the `vdom_2` virtual domain and bind the `vc2link1` interface to the `vdom_3` virtual domain.

```
config system interface
  edit vc2link0
    set vdom vdom_2
  next
  edit vc2link1
    set vdom vdom_3
  end
```

Troubleshooting virtual clustering

Troubleshooting virtual clusters is similar to troubleshooting any cluster (see [FGCP configuration examples and troubleshooting on page 1412](#)). This section describes a few testing and troubleshooting techniques for virtual clustering.

To test the VDOM partitioning configuration

You can do the following to confirm that traffic for different VDOMs will be distributed among both FortiGates in the virtual cluster. These steps assume the cluster is otherwise operating correctly.

1. Log into the GUI or CLI using the IP addresses of interfaces in each VDOM.
Confirm that you have logged into the FortiGate that should be processing traffic for that VDOM by checking the HTML title displayed by your web browser or the CLI prompt. Both of these should include the host name of the cluster unit that you have logged into. Also on the system Dashboard, the System Information widget displays the serial number of the FortiGate that you logged into. From the CLI the `get system status` command displays the status of the cluster unit that you logged into.
2. To verify that the correct cluster unit is processing traffic for a VDOM:
 - Add security policies to the VDOM that allow communication between the interfaces in the VDOM.
 - Optionally enable traffic logging and other monitoring for that VDOM and these security policies.
 - Start communication sessions that pass traffic through the VDOM.
 - Log into the GUI and go to **System > HA**. Verify that the statistics display shows more active sessions, total packets, network utilization, and total bytes for the unit that should be processing all traffic for the VDOM.
 - Optionally check traffic logging and the Top Sessions Widget for the FortiGate that should be processing traffic for that VDOM to verify that the traffic is being processed by this FortiGate.

Full mesh HA

This chapter provides an introduction to full mesh HA and also contains general procedures and configuration examples that describe how to configure FortiGate full mesh HA.

The examples in this chapter include example values only. In most cases you will substitute your own values. The examples in this chapter also do not contain detailed descriptions of configuration parameters.

Full mesh HA overview

When two or more FortiGates are connected to a network in an HA cluster the reliability of the network is improved because the HA cluster replaces a single FortiGate as a single point of failure. With a cluster, a single FortiGate is replaced by a cluster of two or more FortiGates.

However, even with a cluster, potential single points of failure remain. The interfaces of each cluster unit connect to a single switch and that switch provides a single connection to the network. If the switch fails or if the connection between the switch and the network fails service is interrupted to that network.

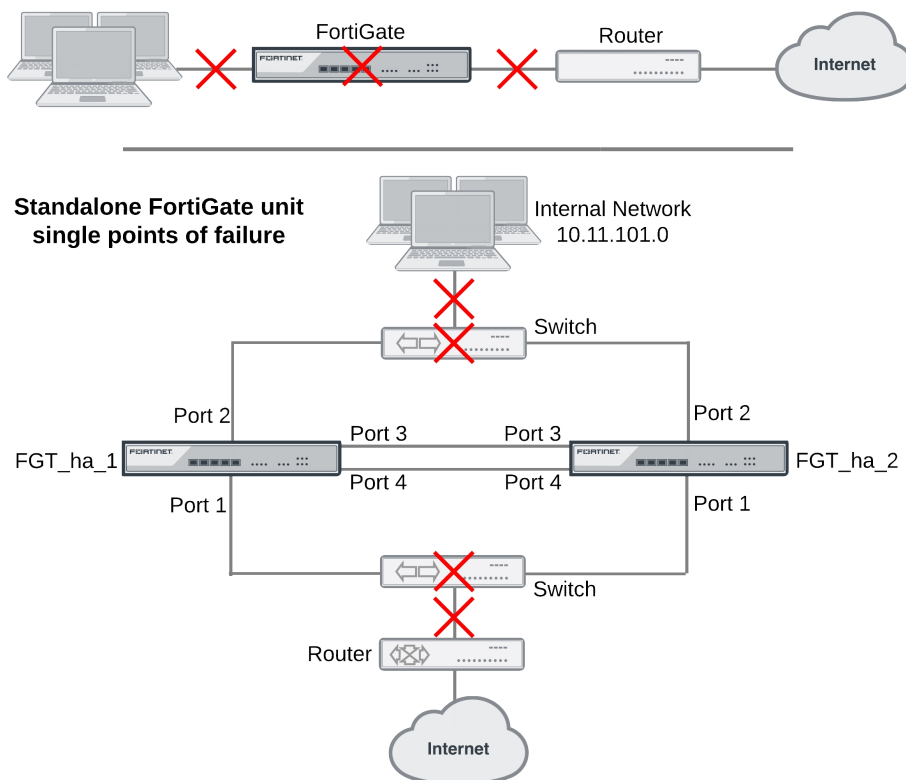

The HA cluster does improve the reliability of the network because switches are not as complex components as FortiGates, so are less likely to fail. However, for even greater reliability, a configuration is required that includes redundant connections between the cluster the networks that it is connected to.

FortiGate models that support 802.3ad Aggregate or Redundant interfaces can be used to create a cluster configuration called full mesh HA. Full mesh HA is a method of reducing the number of single points of failure on a network that includes an HA cluster.

This redundant configuration can be achieved using FortiGate 802.3ad Aggregate or Redundant interfaces and a full mesh HA configuration. In a full mesh HA configuration, you connect an HA cluster consisting of two or more FortiGates to the network using 802.3ad Aggregate or Redundant interfaces and redundant switches. Each 802.3ad Aggregate or Redundant interface is connected to two switches and both of these switches are connected to the network. In addition you must set up an IEEE 802.1Q (also called Dot1Q) or ISL link between the redundant switches connected to the Aggregate or Redundant interfaces.

The resulting full mesh configuration, an example is shown below, includes redundant connections between all network components. If any single component or any single connection fails, traffic automatically switches to the redundant component and connection and traffic flow resumes.

Single points of failure in a standalone and HA network configuration

Full mesh HA and redundant heartbeat interfaces

A full mesh HA configuration also includes redundant HA heartbeat interfaces. At least two heartbeat interfaces should be selected in the HA configuration and both sets of HA heartbeat interfaces should be connected. The HA heartbeat interfaces do not have to be configured as redundant interfaces because the FGCP handles failover between heartbeat interfaces.

Full mesh HA, redundant interfaces and 802.3ad aggregate interfaces

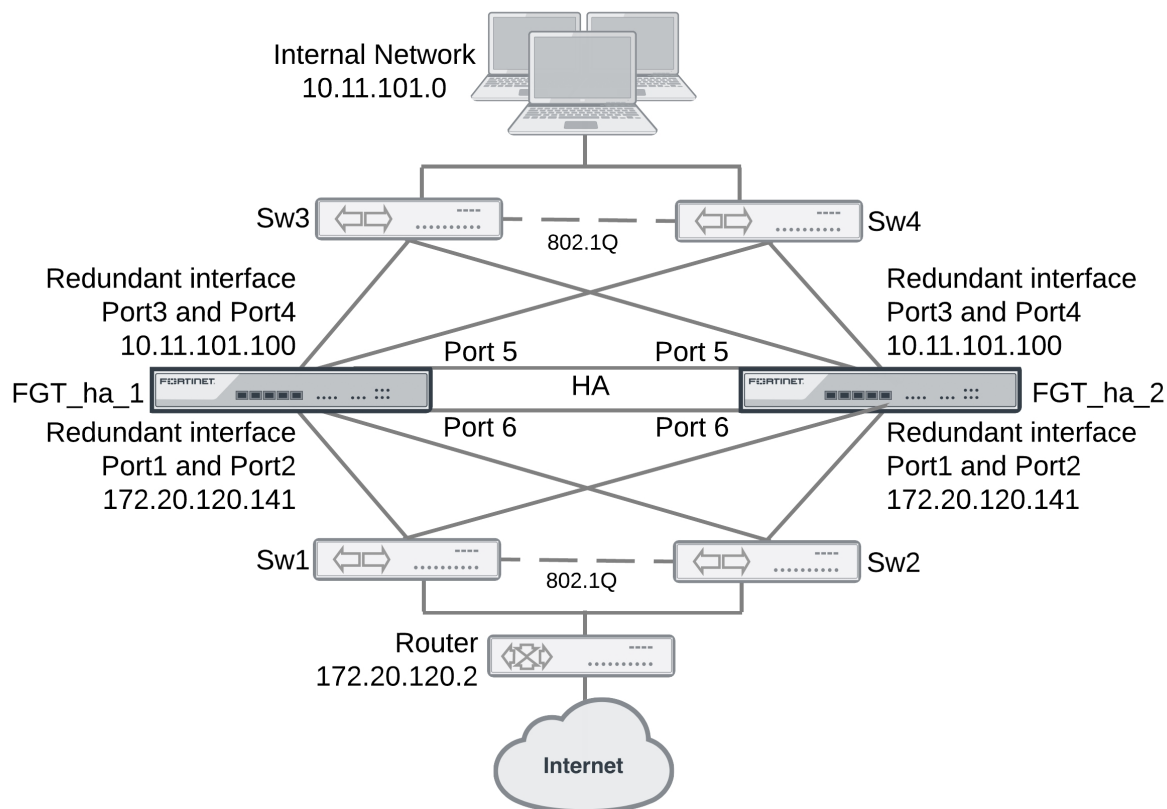

Full mesh HA is supported for both redundant interfaces and 802.3ad aggregate interfaces. In most cases you would simply use redundant interfaces. However, if your switches support 802.3ad aggregate interfaces and split multi-trunking you can use aggregate interfaces in place of redundant interfaces for full mesh HA. One advantage of using aggregate interfaces is that all of the physical interfaces in the aggregate interface can send and receive packets. As a result, using aggregate interfaces may increase the bandwidth capacity of the cluster.

Usually redundant and aggregate interfaces consist of two physical interfaces. However, you can add more than two physical interfaces to a redundant or aggregate interface. Adding more interfaces can increase redundancy protection. Adding more interfaces can also increase bandwidth capacity if you are using 802.3ad aggregate interfaces.

Example full mesh HA configuration

The following figure shows a full mesh HA configuration with a cluster of two FortiGate. This section describes the FortiGate configuration settings and network components required for a full mesh HA configuration. This section also contains example steps for setting up this full mesh HA configuration. The procedures in this section describe one of many possible sequences of steps for configuring full mesh HA. As you become more experienced with FortiOS, HA, and full mesh HA you may choose to use a different sequence of configuration steps.

Full Mesh HA configuration

For simplicity these procedures assume that you are starting with two new FortiGates set to the factory default configuration. However, starting from the default configuration is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

These procedures describe how to configure a cluster operating in NAT mode because NAT is the default FortiGate operating mode. However, the steps are the same if the cluster operates in transparent mode. You can either switch the cluster units to operate in transparent mode before beginning these procedures, or you can switch the cluster to operate in transparent mode after HA is configured and the cluster is connected and operating.

Full mesh HA configuration

The two FortiGates (FGT_ha_1 and FGT_ha_2) can be operating in NAT or transparent mode. Aside from the standard HA settings, the FortiGate configuration includes the following:

- The port5 and port6 interfaces configured as heartbeat interfaces. A full mesh HA configuration also includes redundant HA heartbeat interfaces.
- The port1 and port2 interfaces added to a redundant interface. Port1 is the active physical interface in this redundant interface. To make the port1 interface the active physical interface it should appear above the port2 interface in the redundant interface configuration.
- The port3 and port4 interfaces added to a redundant interface. Port3 is the active physical interface in this redundant interface. To make the port3 interface the active physical interface it should appear above the port4 interface in the redundant interface configuration.

Full mesh switch configuration

The following redundant switch configuration is required:

- Two redundant switches (Sw3 and Sw4) connected to the internal network. Establish an 802.1Q (Dot1Q) or interswitch-link (ISL) connection between them.
- Two redundant switches (Sw1 and Sw2) connected to the internet. Establish an 802.1Q (Dot1Q) or interswitch-link (ISL) connection between them.

Full mesh network connections

Make the following physical network connections for FGT_ha_1:

- Port1 to Sw1 (active)
- Port2 to Sw2 (inactive)
- Port3 to Sw3 (active)
- Port4 to Sw4 (inactive)

Make the following physical network connections for FGT_ha_2:

- Port1 to Sw2 (active)
- Port2 to Sw1 (inactive)
- Port3 to Sw4 (active)
- Port4 to Sw3 (inactive)

How packets travel from the internal network through the full mesh cluster and to the internet

If the cluster is operating in active-passive mode and FGT_ha_2 is the primary unit, all packets take the following path from the internal network to the internet:

1. From the internal network to Sw4. Sw4 is the active connection to FGT_ha_2; which is the primary unit. The primary unit receives all packets.
2. From Sw4 to the FGT_ha_2 port3 interface. Active connection between Sw4 and FGT_ha_2. Port3 is the active member of the redundant interface.
3. From FGT_ha_2 port3 to FGT_ha_2 port1. Active connection between FGT_ha_2 and Sw2. Port1 is the active member of the redundant interface.
4. From Sw2 to the external router and the internet.

Configuring full-mesh HA - GUI

Each cluster unit must have the same HA configuration.

To configure the FortiGates for HA operation

1. Register and apply licenses to the FortiGate.

2. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
3. Enter a new Host Name for this FortiGate.

New Name	FGT_ha_1
-----------------	----------

4. Go to **System > HA** and change the following settings.

Mode	Active-Active	
Group Name	Rexample1.com	
Password	RHA_pass_1	
Heartbeat Interface		
	Enable	Priority
port5	Select	50
port6	Select	50

5. Select **OK**.

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following

virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

6. Power off the first FortiGate.
7. Repeat these steps for the second FortiGate.

Set the second FortiGate host name to:

New Name	FGT_ha_2

To connect the cluster to your network

1. Make the following physical network connections for FGT_ha_1:
 - Port1 to Sw1 (active)
 - Port2 to Sw2 (inactive)
 - Port3 to Sw3 (active)
 - Port4 to Sw4 (inactive)
2. Make the following physical network connections for FGT_ha_2:
 - Port1 to Sw2 (active)
 - Port2 to Sw1 (inactive)
 - Port3 to Sw4 (active)
 - Port4 to Sw3 (inactive)
3. Connect Sw3 and Sw4 to the internal network.
4. Connect Sw1 and Sw2 to the external router.
5. Enable 802.1Q (Dot1Q) or ISL communication between Sw1 and Sw2 and between Sw3 and Sw4.
6. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.

The System Information dashboard widget shows the **Cluster Name** (Rexample1.com) and the host names and serial numbers of the **Cluster Members**. The Unit Operation widget shows multiple cluster units.
2. Go to **System > HA** to view the cluster members list.

The list shows two cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard does not display information for both cluster units the FortiGates are not functioning as a cluster. See [Example full mesh HA configuration on page 1475](#) to troubleshoot the cluster.

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings.

1. Log into the cluster GUI.
2. Go to **System > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.

5. Select **OK**.
6. Go to **Network > Static Routes** and temporarily delete the default route.
You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.
7. Go to **Network > Interfaces** and select **Create New > Interface** and configure the redundant interface to connect to the internet.

Name	Port1_Port2
Type	Redundant
Physical Interface Members	
Selected Interfaces	port1, port2
IP/Netmask	172.20.120.141/24

8. Select **OK**.
9. Select **Create New** and configure the redundant interface to connect to the internal network.

Name	Port3_Port4
Type	Redundant
Physical Interface Members	
Selected Interfaces	port3, port4
IP/Netmask	10.11.101.100/24
Administrative Access	HTTPS, PING, SSH

10. Select **OK**.
The virtual MAC addresses of the FortiGate interfaces change to the following. Notice that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)

- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

11. Go to **Router > Static > Static Routes**.

12. Add the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	Port1_Port2
Distance	10

13. Select **OK**.

To configure HA port monitoring for the redundant interfaces

1. Go to **System > HA**.
2. In the cluster members list, edit the primary unit.
3. Enable **interface monitoring** the **Port1_Port2** and the **Port3_Port4** interfaces
4. Select **OK**.

Configuring full mesh HA - CLI

Each cluster must have the same HA configuration. Use the following procedure to configure the FortiGates for HA operation.

To configure the FortiGates for HA operation

1. Register and apply licenses to the FortiGate.
2. Enter a new Host Name for this FortiGate.

```
config system global
    set hostname FGT_ha_1
end
```

3. Configure HA settings.

```
config system ha
    set mode a-a
    set group-name Rexample1.com
    set password RHA_pass_1
    set hbdev port5 50 port6 50
end
```

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose

connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4. Power off the first FortiGate.
5. Repeat these steps for the second FortiGate.

Set the other FortiGate host name to:

```
config system global
    set hostname FGT_ha_2
end
```

To connect the cluster to your network

1. Make the following physical network connections for FGT_ha_1:
 - Port1 to Sw1 (active)
 - Port2 to Sw2 (inactive)
 - Port3 to Sw3 (active)
 - Port4 to Sw4 (inactive)
2. Make the following physical network connections for FGT_ha_2:
 - Port1 to Sw2 (active)
 - Port2 to Sw1 (inactive)
 - Port3 to Sw4 (active)
 - Port4 to Sw3 (inactive)
3. Connect Sw3 and Sw4 to the internal network.
4. Connect Sw1 and Sw2 to the external router.
5. Enable 802.1Q (Dot1Q) or ISL communication between Sw1 and Sw2 and between Sw3 and Sw4.
6. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. Enter `get system status` to verify the HA status of the cluster unit that you logged into.

If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit.

If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit.

If the command output includes `Current HA mode: standalone` the cluster unit is not operating in HA mode.

3. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
HA Health Status: OK
Model: FortiGate-XXXX
Mode: HA A-P
Group: 0
Debug: 0
Cluster Uptime: 7 days 00:30:26
.
.
.
```

You can use this command to confirm that the cluster is healthy and operating normally, some information about the cluster configuration, and information about how long the cluster has been

operating. Information not shown in this example includes how the primary unit was selected, configuration synchronization status, usage stats for each cluster unit, heartbeat status, and the relative priorities of the cluster units.

4. Use the `execute ha manage` command to connect to the other cluster unit's CLI and use these commands to verify cluster status.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard does not display information for both cluster units the FortiGates are not functioning as a cluster. See [Example full mesh HA configuration on page 1475](#) to troubleshoot the cluster.

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings. Some steps use the CLI and some the GUI.

1. Log into the cluster CLI.
2. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <password_str>
  end
```

3. Temporarily delete the default route.

You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.

```
config router static
  delete 1
end
```

4. Go to **System > Network > Interface** and select **Create New** to add the redundant interface to connect to the internet.
5. Add the redundant interface to connect to the internet.

```
config system interface
  edit Port1_Port2
    set type redundant
    set member port1 port2
  end
```

6. Add the redundant interface to connect to the internal network.

```
config system interface
  edit Port3_Port4
    set type redundant
    set member port3 port4
  end
```

The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01

- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

7. Go to Router > Static > Static Routes.

8. Add the default route.

```
config router static
edit 1
set dst 0.0.0.0 0.0.0.0
set gateway 172.20.120.2
set device Port1_Port2
end
```

To configure HA port monitoring for the redundant interfaces

1. Enter the following command to configure port monitoring for the redundant interfaces:

```
config system ha
set monitor Port1_Port2 Port3_Port4
end
```

Troubleshooting full mesh HA

Troubleshooting full mesh HA clusters is similar to troubleshooting any cluster (see [FGCP configuration examples and troubleshooting on page 1412](#) or [Virtual clusters on page 1463](#)). The configuration and operation of a full mesh HA cluster is very similar to the configuration and operation of a standard cluster. The only differences relate to the configuration, connection, and operation of the redundant interfaces and redundant switches.

- Make sure the redundant interfaces and switches are connected correctly. With so many connections it is possible to make mistakes or for cables to become disconnected.
- Confirm that the configuration of the cluster unit 802.3ad Aggregate or Redundant interfaces is correct according to the configuration procedures in this chapter.
- In some configurations with some switch hardware, MAC-learning delays on the inter-switch links on the surrounding topologies may occur. The delays occur if the gratuitous ARP packets sent by the cluster after a failover

are delayed by the switches before being sent across the inter-switch link. If this happens the surrounding topologies may be delayed in recognizing the failover and will keep sending packets to the MAC address of the failed primary unit resulting in lost traffic. Resolving this problem may require changing the configuration of the switch or replacing them with switch hardware that does not delay the gratuitous ARP packets.

Operating clusters and virtual clusters

With some exceptions, you can operate a cluster in much the same way as you operate a standalone FortiGate. This chapter describes those exceptions and also the similarities involved in operating a cluster instead of a standalone FortiGate.

Operating a cluster

The configurations of all of the FortiGates in a cluster are synchronized so that the cluster units can simulate a single FortiGate. Because of this synchronization, you manage the HA cluster instead of managing the individual cluster units. You manage the cluster by connecting to the GUI using any cluster interface configured for HTTPS or HTTP administrative access. You can also manage the cluster by connecting to the CLI using any cluster interface configured for SSH or telnet administrative access.

The cluster GUI dashboard displays the cluster name, the host name and serial number of each cluster member, and also shows the role of each unit in the cluster. The roles can be master (primary unit) and slave (subordinate units). The dashboard also displays a cluster unit front panel illustration.

You can also go to **System > HA** to view the cluster members list. This includes status information for each cluster unit. You can also use the cluster members list for a number of cluster management functions including changing the HA configuration of an operating cluster, changing the host name and device priority of a subordinate unit, and disconnecting a cluster unit from a cluster. See [Cluster members list on page 1505](#).

You can use log messages to view information about the status of the cluster. See [Clusters and logging on page 1497](#).

You can use SNMP to manage the cluster by configuring a cluster interface for SNMP administrative access. Using an SNMP manager you can get cluster configuration information and receive traps. See [Clusters and SNMP on page 1500](#).

You can configure a reserved management interface to manage individual cluster units. You can use this interface to access the GUI or CLI and to configure SNMP management for individual cluster units. See [Managing individual cluster units using a reserved out-of-band management interface on page 1488](#).

You can manage individual cluster units by using SSH, telnet, or the CLI console on the GUI dashboard to connect to the CLI of the cluster. From the CLI you can use the `execute ha manage` command to connect to the CLI of any unit in the cluster.

You can also manage individual cluster units by using a null-modem cable to connect to any cluster unit CLI. From there you can use the `execute ha manage` command to connect to the CLI of each unit in the cluster.

Operating a virtual cluster

Managing a virtual cluster is very similar to managing a cluster that does not contain multiple virtual domains. Most of the information in this chapter applies to managing both kinds of clusters. This section describes what is different when managing a virtual cluster.

If virtual domains are enabled, the cluster GUI dashboard displays the cluster name and the role of each cluster unit in virtual cluster 1 and virtual cluster 2.

The configuration and maintenance options that you have when you connect to a virtual cluster GUI or CLI depend on the virtual domain that you connect to and the administrator account that you use to connect.

If you connect to a cluster as the administrator of a virtual domain, you connect directly to the virtual domain. Since HA virtual clustering is a global configuration, virtual domain administrators cannot see HA configuration options. However, virtual domain administrators see the host name of the cluster unit that they are connecting to on the web browser title bar or CLI prompt. This host name is the host name of the primary unit for the virtual domain. Also, when viewing log messages the virtual domain administrator can select to view log messages for either of the cluster units.

If you connect to a virtual cluster as the admin administrator you connect to the global GUI or CLI. Even so, you are connecting to an interface and to the virtual domain that the interface has been added to. The virtual domain that you connect to does not make a difference for most configuration and maintenance operations. However, there are a few exceptions. You connect to the FortiGate that functions as the primary unit for the virtual domain. So the host name displayed on the web browser title bar and on the CLI is the host name of this primary unit.

Managing individual cluster units using a reserved out-of-band management interface

You can provide direct management access to all cluster units by reserving up to four management interfaces as part of the HA configuration. Once a management interface is reserved, you can configure a different IP address, administrative access and other interface settings for each management interface for each cluster unit. Then by connecting these interfaces of each cluster unit to your network you can manage each cluster unit separately from different IP addresses. Configuration changes to the reserved management interfaces are not synchronized to other cluster units.

You can also configure an in-band management interface for a cluster unit. See ["Managing individual cluster units using an in-band management IP address" on page 1494](#).

Reserved management interfaces provide direct management access to each cluster unit and give each cluster unit a different identity on your network. This simplifies using external services, such as SNMP, to separately monitor and manage each cluster unit.

The reserved management interfaces are not assigned HA virtual MAC addresses like other cluster interfaces. Instead the reserved management interfaces retain the permanent hardware address of the physical interface unless you change it using the `config system interface` command.

Reserved management interfaces and their IP addresses should not be used for managing a cluster using FortiManager. To correctly manage a FortiGate HA cluster with FortiManager use the IP address of one of the cluster unit interfaces.

If you enable SNMP administrative access for a reserved management interface you can use SNMP to monitor each cluster unit using the reserved management interface IP address. To monitor each cluster unit using SNMP, just add the IP address of each cluster unit's reserved management interface to the SNMP server configuration. You must also enable direct management of cluster members in the cluster SNMP configuration.

If you enable HTTPS or HTTP administrative access for the reserved management interfaces you can connect to the GUI of each cluster unit. Any configuration changes made to any of the cluster units is automatically synchronized to all cluster units. From the subordinate units the GUI has the same features as the primary unit except that unit-specific information is displayed for the subordinate unit, for example:

- The **Dashboard System Information** widget displays the subordinate unit serial number but also displays the same information about the cluster as the primary unit

- On the Cluster members list (go to **System > HA**) you can change the HA configuration of the subordinate unit that you are logged into. For the primary unit and other subordinate units you can change only the host name and device priority.
- Log Access displays the logs of the subordinate that you are logged into first. You use the HA Cluster list to view the log messages of other cluster units including the primary unit.

If you enable SSH or TELNET administrative access for the reserved management interfaces you can connect to the CLI of each cluster unit. The CLI prompt contains the host name of the cluster unit that you have connected to. Any configuration changes made to any of the cluster units is automatically synchronized to all cluster units. You can also use the `execute ha manage` command to connect to other cluster unit CLIs.

The reserved management interface is available in NAT and in transparent mode. It is also available if the cluster is operating with multiple VDOMs. In transparent mode you cannot normally add an IP address to an interface. However, you can add an IP address to the reserved management interface.

Using an HA reserved management interface for FortiSandbox, SNMP and other management services

By default, management services such as SNMP, remote logging, remote authentication and communication with FortiSandbox and so on use a cluster interface. As a result communication from each cluster unit comes from a cluster interface instead of from the interface of an individual cluster unit and not from the HA reserved management interface.

If you want to use a HA reserved management interface for these features you must enter the following command:

```
config system ha
    set ha-direct enable
end
```

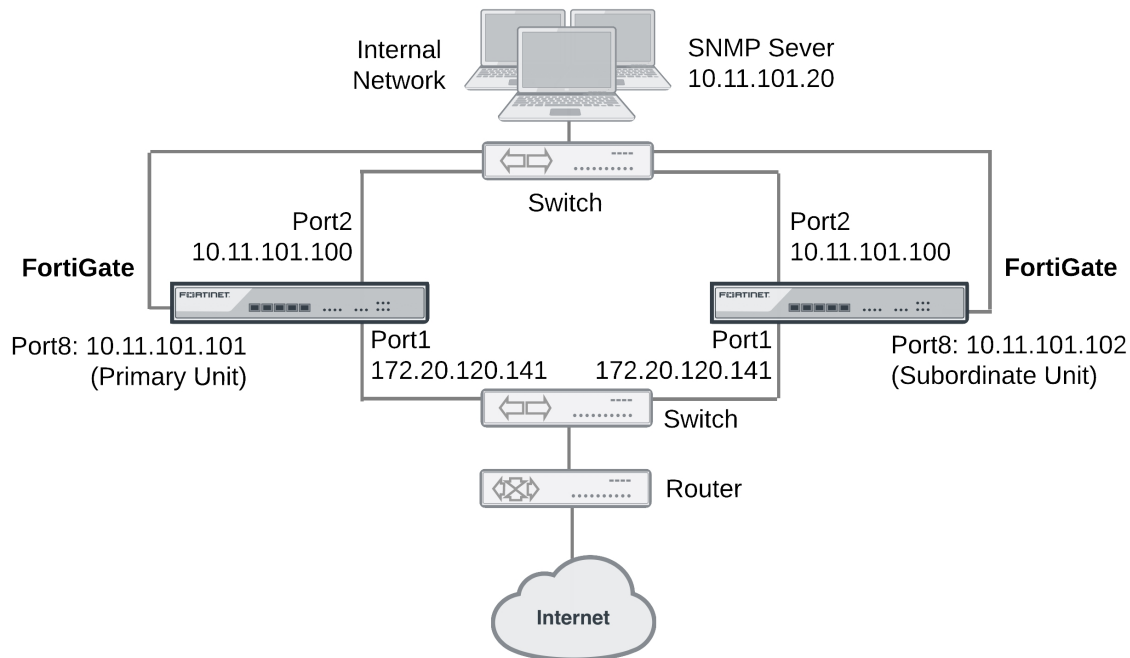

The result is that all management services can use the HA reserved management interfaces. This means that individual cluster units send log messages and communicate with FortiSandbox and so on using the HA reserved management interfaces instead of one of the cluster interfaces. This allows you to manage each cluster unit separately and to separate the management traffic from each cluster unit. This can also be useful if each cluster unit is in a different location.

If you just want to use HA reserved management interfaces for SNMP remote management you can enable `ha-direct` in the SNMP configuration as shown in the following example.

Configuring the reserved management interface and SNMP remote management of individual cluster units

This example describes how to configure SNMP remote management of individual cluster units using an HA reserved management interface. The configuration consists of two FortiGate-620B units already operating as a cluster. In the example, the port8 interface of each cluster unit is connected to the internal network using the switch and configured as the reserved management interface.

SNMP remote management of individual cluster units

To configure the reserved management interface - GUI

From the GUI you can also configure IPv4 and IPv6 default routes that are only used by the reserved management interface.

1. Go to **System > HA**.
2. Edit the primary unit.
3. Select **Management Interface Reservation** and select port8.
4. Set **Gateway** to 10.11.101.2.
5. Set **IPv6 Gateway** to 2001:db8:0:2::20
6. Select **OK**.

To configure the reserved management interface - CLI

From the CLI you can also configure IPv4 and IPv6 default routes that are only used by the reserved management interface.

1. Log into the CLI of any cluster unit.
2. Enter the following command to enable the reserved management interface, set port8 as the reserved interface, and add an IPv4 default route of 10.11.101.2 and an IPv6 default route of 2001:db8:0:2::20 for the reserved management interface.

```
config system ha
  set ha-mgmt-status enable
  config ha-mgmt-interfaces
    edit 1
      set interface port8
```

```

set gateway 10.11.101.2
set gateway6 2001:db8:0:2::20
end

```

The reserved management interface default route is not synchronized to other cluster units.

To change the primary unit reserved management interface configuration - GUI

You can change the IP address of the primary unit reserved management interface from the primary unit GUI. Configuration changes to the reserved management interface are not synchronized to other cluster units.

1. From a PC on the internal network, browse to <http://10.11.101.100> and log into the cluster GUI.

This logs you into the primary unit GUI.

You can identify the primary unit from its serial number or host name that appears on the System Information dashboard widget.

2. Go to **Network > Interfaces** and edit the port8 interface as follows:

Alias	primary_reserved
IP/Netmask	10.11.101.101/24
Administrative Access	Ping, SSH, HTTPS, SNMP

3. Select **OK**.

You can now log into the primary unit GUI by browsing to <https://10.11.101.101>. You can also log into this primary unit CLI by using an SSH client to connect to 10.11.101.101.

To change subordinate unit reserved management interface configuration - CLI

At this point you cannot connect to the subordinate unit reserved management interface because it does not have an IP address. Instead, this procedure describes connecting to the primary unit CLI and using the `execute ha manage` command to connect to subordinate unit CLI to change the port8 interface. You can also use a serial connection to the cluster unit CLI. Configuration changes to the reserved management interface are not synchronized to other cluster units.

1. Connect to the primary unit CLI and use the `execute ha manage` command to connect to a subordinate unit CLI.

You can identify the subordinate unit from its serial number or host name. The host name appears in the CLI prompt.

2. Enter the following command to change the port8 IP address to 10.11.101.102 and set management access to HTTPS, ping, SSH, and SNMP.

```

config system interface
  edit port8
    set ip 10.11.101.102/24
    set allowaccess https ping ssh snmp
  end

```

You can now log into the subordinate unit GUI by browsing to <https://10.11.101.102>. You can also log into this subordinate unit CLI by using an SSH client to connect to 10.11.101.102.

To configure the cluster for SNMP management using the reserved management interfaces - CLI

This procedure describes how to configure the cluster to allow the SNMP server to get status information from the primary unit and the subordinate unit. The SNMP configuration is synchronized to all cluster units. To support using the reserved management interfaces, you must add at least one HA direct management host to an SNMP community. If your SNMP configuration includes SNMP users with user names and passwords you must also enable HA direct management for SNMP users.

1. Enter the following command to add an SNMP community called `Community` and add a host to the community for the reserved management interface of each cluster unit. The host includes the IP address of the SNMP server (10.11.101.20).

```
config system snmp community
edit 1
set name Community
config hosts
edit 1
set ha-direct enable
set ip 10.11.101.20
end
end
```

Enabling ha-direct in non-HA environments makes SNMP unusable.

- 2.
3. Enter the following command to add an SNMP user for the reserved management interface.

```
config system snmp user
edit 1
set ha-direct enable
set notify-hosts 10.11.101.20
end
```

Configure other settings as required.

To get CPU, memory, and network usage of each cluster unit using the reserved management IP addresses

From the command line of an SNMP manager, you can use the following SNMP commands to get CPU, memory and network usage information for each cluster unit. In the examples, the community name is `Community`. The commands use the MIB field names and OIDs listed below.

Enter the following commands to get CPU, memory and network usage information for the primary unit with reserved management IP address 10.11.101.101 using the MIB fields:

```
snmpget -v2c -c Community 10.11.101.101 fgHaStatsCpuUsage
snmpget -v2c -c Community 10.11.101.101 fgHaStatsMemUsage
snmpget -v2c -c Community 10.11.101.101 fgHaStatsNetUsage
```

Enter the following commands to get CPU, memory and network usage information for the primary unit with reserved management IP address 10.11.101.101 using the OIDs:

```
snmpget -v2c -c Community 10.11.101.101 1.3.6.1.4.1.12356.101.13.2.1.1.3.1
snmpget -v2c -c Community 10.11.101.101 1.3.6.1.4.1.12356.101.13.2.1.1.4.1
snmpget -v2c -c Community 10.11.101.101 1.3.6.1.4.1.12356.101.13.2.1.1.5.1
```

Enter the following commands to get CPU, memory and network usage information for the subordinate unit with reserved management IP address 10.11.101.102 using the MIB fields:

```
snmpget -v2c -c Community 10.11.101.102 fgHaStatsCpuUsage
snmpget -v2c -c Community 10.11.101.102 fgHaStatsMemUsage
snmpget -v2c -c Community 10.11.101.102 fgHaStatsNetUsage
```

Enter the following commands to get CPU, memory and network usage information for the subordinate unit with reserved management IP address 10.11.101.102 using the OIDs:

```
snmpget -v2c -c Community 10.11.101.102 1.3.6.1.4.1.12356.101.13.2.1.1.3.1
snmpget -v2c -c Community 10.11.101.102 1.3.6.1.4.1.12356.101.13.2.1.1.4.1
snmpget -v2c -c Community 10.11.101.102 1.3.6.1.4.1.12356.101.13.2.1.1.5.1
```

Adding firewall local-in policies for the dedicated HA management interface

To add local-in policies for the dedicated management interface, enable `ha-mgmt-intf-only` and set `intf` to `any`. Enabling `ha-mgmt-intf-only` means the local-in policy applies only to the VDOM that contains the dedicated HA management interface. For example:

```
config firewall local-in-policy
edit 0
set ha-mgmt-intf-only enable
set intf any
set srcaddr internal-net
set dstaddr mgmt-int
set action accept
set service HTTPS
set schedule weekdays
end
```

NTP over dedicated HA management interfaces

If you set up dedicated management interfaces on each cluster unit, if NTP is enabled, the primary unit contacts an NTP server using the dedicated management interface. System time is then synchronized to the backup units through the HA heartbeat.

Example CLI:

```
config system interface
edit port5
set ip 172.16.79.46 255.255.255.0
end

config system ha
set group-name FGT-HA
set mode a-p
set ha-mgmt-status enable
config ha-mgmt-interfaces
edit 1
set interface port5
set gateway 172.16.79.1
end
set ha-direct enable
end

config system ntp
set ntpsync enable
set syncinterval 5
```

```
end
```

Managing individual cluster units using an in-band management IP address

You can use the following command to add an in-band management IP address to an individual cluster unit interface that is also connected to a network and processing traffic. The in-band management IP address is an alternative to the reserved HA management interface feature and does not require reserving an interface just for management access.

```
config system interface
  edit port1
    set management-ip 172.20.121.155/24
  end
```

The management IP address is accessible from the network that the cluster interface is connected to. This setting is not synchronized so each cluster unit can have their own in-band management IP addresses. You can add a management IP address to one or more interfaces of each cluster unit.

The in-band management IP address should be on the same subnet as the interface you are adding it to, but cannot be on the same subnet as other interface IP addresses.

You can connect to the in-band management IP address using the interface's administrative access settings. The in-band management IP only supports the following subset of administrative access settings: ping, Telnet, HTTP, HTTPS, and SNMP.

For example, use the following command to add an in-band management IP address and allow access using HTTPS, SSH and SNMP:

```
config system interface
  edit port23
    set management-ip 172.25.12.5/24
    set allowaccess https ssh snmp
  end
```

Managing individual cluster units in a virtual cluster

You can select the HA option **Do NOT Synchronize Management VDOM Configuration** if you have enabled multiple VDOMS and set a VDOM other than the root VDOM to be the management VDOM. You can select this option to prevent the management VDOM configuration from being synchronized between cluster units in a virtual cluster. This allows you to add an interface to the VDOM in each cluster unit and then to give the interfaces different IP addresses in each cluster unit, allowing you to manage each cluster unit separately.

You can also enable this feature using the following command:

```
config system ha
  set standalone-mgmt-vdom enable
end
```

This feature must be disabled to manage a cluster using FortiManager.

Shutting down or rebooting the primary unit

You can shutdown or reboot the primary unit from the primary unit GUI by selecting **Shutdown** or **Reboot** from the **Admin** menu. From the primary unit CLI you can use the `execute reboot` or `execute shutdown` commands to shutdown or reboot the primary unit.

During the shutdown the primary unit first becomes the backup unit before shutting down allowing the backup unit to become the new primary unit and avoiding a split brain scenario. This behavior only happens when you manually shutdown or reboot the primary unit.

The primary unit acts as a router for subordinate unit management traffic

HA uses routing and inter-VDOM links to route subordinate unit management traffic through the primary unit to the network. Similar to a standalone FortiGate, subordinate units may generate their own management traffic, including:

- DNS queries.
- FortiGuard Web Filtering rating requests.
- Log messages to be sent to a FortiAnalyzer unit, to a syslog server, or to the FortiGuard Analysis and Management Service.
- Log file uploads to a FortiAnalyzer unit.
- Quarantine file uploads to a FortiAnalyzer unit.
- SNMP traps.
- Communication with remote authentication servers (RADIUS, LDAP, TACACS+ and so on)

Subordinate units send this management traffic over the HA heartbeat link to the primary unit. The primary unit forwards the management traffic to its destination. The primary unit also routes replies back to the subordinate unit in the same way.

HA uses a hidden VDOM called `vsys_ha` for HA operations. The `vsys_ha` VDOM includes the HA heartbeat interfaces, and all communication over the HA heartbeat link goes through the `vsys_ha` VDOM. To provide communication from a subordinate unit to the network, HA adds hidden inter-VDOM links between the primary unit management VDOM and the primary unit `vsys_ha` VDOM. By default, `root` is the management VDOM.

Management traffic from the subordinate unit originates in the subordinate unit `vsys_ha` VDOM. The `vsys_ha` VDOM routes the management traffic over the HA heartbeat link to the primary unit `vsys_ha` VDOM. This management traffic is then routed to the primary unit management VDOM and from there out onto the network.

DNS queries and FortiGuard Web Filtering and Email Filter requests are still handled by the HA proxy so the primary unit and subordinate units share the same DNS query cache and the same FortiGuard Web Filtering and Email Filter cache. In a virtual clustering configuration, the cluster unit that is the primary unit for the management virtual domain maintains the FortiGuard Web Filtering, Email Filtering, and DNS query cache.

Subordinate unit management traffic path

Cluster communication with RADIUS and LDAP servers

In an active-passive cluster, only the primary unit processes traffic, so the primary unit communicates with RADIUS or LDAP servers. In a cluster that is operating in active-active mode, subordinate units send RADIUS and LDAP requests to the primary unit over the HA heartbeat link and the primary unit routes them to their destination. The primary unit relays the responses back to the subordinate unit.

Clusters and FortiGuard services

This section describes how various FortiGate HA clustering configurations communicate with the FDN.

In an operating cluster, the primary unit communicates directly with the FortiGuard Distribution Network (FDN). Subordinate units also communicate directly with the FDN but as described above, all communication between subordinate units and the FDN is routed through the primary unit.

You must register and license all of the units in a cluster for all required FortiGuard services, both because all cluster units communicate with the FDN and because any cluster unit could potentially become the primary unit.

FortiGuard and active-passive clusters

For an active-passive cluster, only the primary unit processes traffic. Even so, all cluster units communicate with the FDN. Only the primary unit sends FortiGuard Web Filtering and Antispam requests to the FDN. All cluster units receive FortiGuard Antivirus, IPS, and application control updates from the FDN.

In an active-passive cluster the FortiGuard Web Filter and Email Filter caches are located on the primary unit in the same way as for a standalone FortiGate. The caches are not shared among cluster units so after a failover the new primary unit must build up new caches.

In an active-passive cluster all cluster units also communicate with the FortiGuard Analysis and Management Service (FAMS).

FortiGuard and active-active clusters

For an active-active cluster, both the primary unit and the subordinate units process traffic. Communication between the cluster units and the FDN is the same as for active-passive clusters with the following exception.

Because the subordinate units process traffic, they may also be making FortiGuard Web Filtering and Email Filter requests. The primary unit receives all such requests from the subordinate units and relays them to the FDN and then relays the FDN responses back to the subordinate units. The FortiGuard Web Filtering and Email Filtering

URL caches are maintained on the primary unit. The primary unit caches are used for primary and subordinate unit requests.

FortiGuard and virtual clustering

For a virtual clustering configuration the management virtual domain of each cluster unit communicates with the FDN. The cluster unit that is the primary unit for the management virtual domain maintains the FortiGuard Web Filtering and Email Filtering caches. All FortiGuard Web Filtering and Email Filtering requests are proxied by the management VDOM of the cluster unit that is the primary unit for the management virtual domain.

Clusters and logging

This section describes the log messages that provide information about how HA is functioning, how to view and manage logs for each unit in a cluster, and provides some example log messages that are recorded during specific cluster events.

You configure logging for a cluster in the same way as you configuring logging for a standalone FortiGate. Log configuration changes made to the cluster are synchronized to all cluster units.

All cluster units record log messages separately to the individual cluster unit's log disk, to the cluster unit's system memory, or both. You can view and manage log messages for each cluster unit from the cluster GUI Log Access page.

When remote logging is configured, all cluster units send log messages to remote FortiAnalyzer units or other remote servers as configured. HA uses routing and inter-VDOM links to route subordinate unit log traffic through the primary unit to the network.

When you configure a FortiAnalyzer unit to receive log messages from a FortiGate cluster, you should add a cluster to the FortiAnalyzer unit configuration so that the FortiAnalyzer unit can receive log messages from all cluster units.

Viewing and managing log messages for individual cluster units

This section describes how to view and manage log messages for an individual cluster unit.

To view HA cluster log messages

1. Log into the cluster GUI.
2. Go to **Log&Report > Log Config > Log Settings > GUI Preferences** and select to display logs from **Memory, Disk or FortiAnalyzer**.

For each log display, the **HA Cluster** list displays the serial number of the cluster unit for which log messages are displayed. The serial numbers are displayed in order in the list.

3. Set **HA Cluster** to the serial number of one of the cluster units to display log messages for that unit.

About HA event log messages

HA event log messages always include the host name and serial number of the cluster unit that recorded the message. HA event log messages also include the HA state of the unit and also indicate when a cluster unit switches (or moves) from one HA state to another. Cluster units can operate in the HA states listed below:

HA states

Hello	A FortiGate configured for HA operation has started up and is looking for other FortiGates with which to form a cluster.
Work	In an active-passive cluster a cluster unit is operating as the primary unit. In an active-active cluster unit is operating as the primary unit or a subordinate unit.
Standby	In an active-passive cluster the cluster unit is operating as a subordinate unit.

HA log Event log messages also indicate the virtual cluster that the cluster unit is operating in as well as the member number of the unit in the cluster. If virtual domains are not enabled, all clusters unit are always operating in virtual cluster 1. If virtual domains are enabled, a cluster unit may be operating in virtual cluster 1 or virtual cluster 2. The member number indicates the position of the cluster unit in the cluster members list. Member 0 is the primary unit. Member 1 is the first subordinate unit, member 2 is the second subordinate unit, and so on.

HA log messages

See the FortiOS log message reference for a listing of and descriptions of the HA log messages.

FortiGate HA message "HA master heartbeat interface <intf_name> lost neighbor information"

The following HA log messages may be recorded by an operating cluster:

```
2009-02-16 11:06:34 device_id=FG2001111111 log_id=0105035001 type=event subtype=ha
pri=critical vd=root msg="HA slave heartbeat interface internal lost neighbor information"
```

```
2009-02-16 11:06:40 device_id=FG2001111111 log_id=0105035001 type=event subtype=ha
pri=notice vd=root msg="Virtual cluster 1 of group 0 detected new joined HA member"
```

```
2009-02-16 11:06:40 device_id=FG2001111111 log_id=0105035001 type=event subtype=ha
pri=notice vd=root msg="HA master heartbeat interface internal get peer information"
```

These log messages indicate that the cluster units could not connect to each other over the HA heartbeat link for the period of time that is given by hb-interval x hb-lost-threshold, which is 1.2 seconds with the default values.

To diagnose this problem

1. Check all heartbeat interface connections including cables and switches to make sure they are connected and operating normally.
2. Use the following commands to display the status of the heartbeat interfaces.

```
get hardware nic <heartbeat_interface_name>
diagnose hardware deviceinfo nic <heartbeat_interface_name>
```

The status information may indicate the interface status and link status and also indicate if a large number of errors have been detected.
3. If the log message only appears during peak traffic times, increase the tolerance for missed HA heartbeat packets by using the following commands to increase the lost heartbeat threshold and heartbeat interval:

```
config system ha
  set hb-lost-threshold 12
  set hb-interval 4
end
```

These settings multiply by 4 the loss detection interval. You can use higher values as well.

This condition can also occur if the cluster units are located in different buildings or even different geographical locations. Called a distributed cluster, as a result of the separation it may take a relatively long time for heartbeat packets to be transmitted between cluster units. You can support a distributed cluster by increasing the heartbeat interval so that the cluster expects extra time between heartbeat packets.

4. Optionally disable session-pickup to reduce the processing load on the heartbeat interfaces.
5. Instead of disabling session-pickup you can enable `session-pickup-delay` to reduce the number of sessions that are synchronized. With this option enabled only sessions that are active for more than 30 seconds are synchronized.

It may be useful to monitor CPU and memory usage to check for low memory and high CPU usage. You can configure event logging to monitor CPU and memory usage. You can also enable the CPU over usage and memory low SNMP events.

Once this monitoring is in place, try and determine if there have been any changes in the network or an increase of traffic recently that could be the cause. Check to see if the problem happens frequently and if so what the pattern is.

To monitor the CPU of the cluster units and troubleshoot further, use the following procedure and commands:

```
get system performance status
get system performance top 2
diagnose sys top 2
```

These commands repeated at frequent intervals will show the activity of the CPU and the number of sessions.

Search the Fortinet Knowledge Base for articles about monitoring CPU and Memory usage.

If the problem persists, gather the following information (a console connection might be necessary if connectivity is lost) and provide it to Technical Support when opening a ticket:

- Debug log from the GUI: **System > Advanced > Download Debug Log**
- CLI command output:

```
diagnose sys top 2 (keep it running for 20 seconds)
get system performance status (repeat this command multiple times to get good samples)
get system ha status
diagnose sys ha status
diagnose sys ha dump-by {all options}
diagnose netlink device list
diagnose hardware deviceinfo nic <heartbeat-interface-name>
execute log filter category 1
execute log display
```

Formatting cluster unit hard disks (log disks)

If you need to format the hard disk (also called log disk or disk storage) of one or more cluster units you should disconnect the unit from the cluster and use the `execute formatlogdisk` command to format the cluster unit hard disk then add the unit back to the cluster.

For information about how to remove a unit from a cluster and add it back, see [Disconnecting a cluster unit from a cluster on page 1518](#) and [Adding a disconnected FortiGate back to its cluster on page 1519](#).

Once you add the cluster unit with the formatted log disk back to the cluster you should make it the primary unit before removing other units from the cluster to format their log disks and then add them back to the cluster.

Clusters and SNMP

You can use SNMP to manage a cluster by configuring a cluster interface for SNMP administrative access. Using an SNMP manager you can get cluster configuration and status information and receive traps.

You configure SNMP for a cluster in the same way as configuring SNMP for a standalone FortiGate. SNMP configuration changes made to the cluster are shared by all cluster units.

Each cluster unit sends its own traps and SNMP manager systems can use SNMP get commands to query each cluster unit separately. To set SNMP get queries to each cluster unit you must create a special get command that includes the serial number of the cluster unit.

Alternatively you can use the HA reserved management interface feature to give each cluster unit a different management IP address. Then you can create an SNMP get command for each cluster unit that just includes the management IP address and does not have to include the serial number.

SNMP get command syntax for the primary unit

Normally, to get configuration and status information for a standalone FortiGate or for a primary unit, an SNMP manager would use an SNMP get commands to get the information in a MIB field. The SNMP get command syntax would be similar to the following:

```
snmpget -v2c -c <community_name> <address_ipv4> {<OID> | <MIB_field>}
```

where:

<community_name> is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. The most commonly used community name is public.

<address_ipv4> is the IP address of the FortiGate interface that the SNMP manager connects to.

{<OID> | <MIB_field>} is the object identifier (OID) for the MIB field or the MIB field name itself. The HA MIB fields and OIDs are listed below:

SNMP field names and OIDs

MIB field	OID	Description
fgHaSystemMode	.1.3.6.1.4.1.12356.101.13.1.1.0	HA mode (standalone, a-a, or a-p)
fgHaGroupId	.1.3.6.1.4.1.12356.101.13.1.2.0	The HA group ID of the cluster unit.
fgHaPriority	.1.3.6.1.4.1.12356.101.13.1.3.0	The HA priority of the cluster unit. Default 128.
fgHaOverride	.1.3.6.1.4.1.12356.101.13.1.4.0	Whether HA override is disabled or enabled for the cluster unit.
fgHaAutoSync	.1.3.6.1.4.1.12356.101.13.1.5.0	Whether automatic HA synchronization is disabled or enabled.

MIB field	OID	Description
fgHaSchedule	.1.3.6.1.4.1.12356.101.13.1.6.0	The HA load balancing schedule. Set to none unless operating in a-p mode.
fgHaGroupName	.1.3.6.1.4.1.12356.101.13.1.7.0	The HA group name.
fgHaStatsIndex	.1.3.6.1.4.1.12356.101.13.2.1.1.1.1	An index value that identifies the FortiGates in an HA cluster. The index is always 1 for the FortiGate that receives the HA get. The other FortiGate(s) in the cluster will have an index of 2, 3, or 4. For example, if you get the stats index from the primary FortiGate, the primary FortiGate will have a stats index of 1 and the backup FortiGate will have a stats index of 2. If you get the stats index from the backup unit, the backup unit will have a stats index of 1 and the primary unit will have a stats index of 2.
fgHaStatsSerial	.1.3.6.1.4.1.12356.101.13.2.1.1.2.1	The serial number of the cluster unit.
fgHaStatsCpuUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.3.1	The cluster unit's current CPU usage.
fgHaStatsMemUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.4.1	The cluster unit's current Memory usage.
fgHaStatsNetUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.5.1	The cluster unit's current Network bandwidth usage.
fgHaStatsSesCount	.1.3.6.1.4.1.12356.101.13.2.1.1.6.1	The cluster unit's current session count.
fgHaStatsPktCount	.1.3.6.1.4.1.12356.101.13.2.1.1.7.1	The cluster unit's current packet count.
fgHaStatsByteCount	.1.3.6.1.4.1.12356.101.13.2.1.1.8.1	The cluster unit's current byte count.
fgHaStatsIdsCount	.1.3.6.1.4.1.12356.101.13.2.1.1.9.1	The number of attacks reported by the IPS for the cluster unit.
fgHaStatsAvCount	.1.3.6.1.4.1.12356.101.13.2.1.1.10.1	The number of viruses reported by the antivirus system for the cluster unit.
fgHaStatsHostname	.1.3.6.1.4.1.12356.101.13.2.1.1.11.1	The hostname of the cluster unit.

To get the HA priority for the primary unit

The following SNMP get command gets the HA priority for the primary unit. The community name is `public`. The IP address of the cluster interface configured for SNMP management access is `10.10.10.1`. The HA priority MIB field is `fgHaPriority` and the OID for this MIB field is `1.3.6.1.4.1.12356.101.13.1.3.0`. The first command uses the MIB field name and the second uses the OID:

```
snmpget -v2c -c public 10.10.10.1 fgHaPriority
```

```
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.1.3.0
```

SNMP get command syntax for any cluster unit

To get configuration status information for a specific cluster unit (for the primary unit or for any subordinate unit), the SNMP manager must add the serial number of the cluster unit to the SNMP get command after the community name. The community name and the serial number are separated with a dash. The syntax for this SNMP get command would be:

```
snmpget -v2c -c <community_name>-<fgt_serial> <address_ipv4> {<OID> | <MIB_field>}
```

where:

<community_name> is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. All units in the cluster have the same community name. The most commonly used community name is `public`.

<fgt_serial> is the serial number of any cluster unit. For example, FGT4002803033172. You can specify the serial number of any cluster unit, including the primary unit, to get information for that unit.

<address_ipv4> is the IP address of the FortiGate interface that the SNMP manager connects to.

{<OID> | <MIB_field>} is the object identifier (OID) for the MIB field or the MIB field name itself.

If the serial number matches the serial number of a subordinate unit, the SNMP get request is sent over the HA heartbeat link to the subordinate unit. After processing the request, the subordinate unit sends the reply back over the HA heartbeat link back to the primary unit. The primary unit then forwards the response back to the SNMP manager.

If the serial number matches the serial number of the primary unit, the SNMP get request is processed by the primary unit. You can actually add a serial number to the community name of any SNMP get request. But normally you only need to do this for getting information from a subordinate unit.

To get the CPU usage for a subordinate unit

The following SNMP get command gets the CPU usage for a subordinate unit in a FortiGate-5001SX cluster. The subordinate unit has serial number FG50012205400050. The community name is `public`. The IP address of the FortiGate interface is 10.10.10.1. The HA status table MIB field is `fgHaStatsCpuUsage` and the OID for this MIB field is 1.3.6.1.4.1.12356.101.13.2.1.1.3.1. The first command uses the MIB field name and the second uses the OID for this table:

```
snmpget -v2c -c public-FG50012205400050 10.10.10.1 fgHaStatsCpuUsage
snmpget -v2c -c public-FG50012205400050 10.10.10.1 1.3.6.1.4.1.12356.101.13.2.1.1.3.1
```

FortiGate SNMP recognizes the community name with syntax `<community_name>-<fgt_serial>`. When the primary unit receives an SNMP get request that includes the community name followed by serial number, the FGCP extracts the serial number from the request. Then the primary unit redirects the SNMP get request to the cluster unit with that serial number. If the serial number matches the serial number of the primary unit, the SNMP get is processed by the primary unit.

Getting serial numbers of cluster units

The following SNMP get commands use the MIB field name `fgHaStatsSerial.<index>` to get the serial number of each cluster unit. Where `<index>` is the cluster unit's cluster index and 1 is the cluster index of the primary unit, 2 is the cluster index of the first subordinate unit, and 3 is the cluster index of the second subordinate unit.

The OID for this MIB field is 1.3.6.1.4.1.12356.101.13.2.1.1.2.1. The community name is `public`. The IP address of the FortiGate interface is 10.10.10.1.

The first command uses the MIB field name and the second uses the OID for this table and gets the serial number of the primary unit:

```
snmpget -v2c -c public 10.10.10.1 fgHaStatsSerial.1
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.2.1.1.2.1
```

The second command uses the MIB field name and the second uses the OID for this table and gets the serial number of the first subordinate unit:

```
snmpget -v2c -c public 10.10.10.1 fgHaStatsSerial.2
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.2.2.2
```

SNMP get command syntax - reserved management interface enabled

To get configuration and status information for any cluster unit where you have enabled the HA reserved management interface feature and assigned IP addresses to the management interface of each cluster unit, an SNMP manager would use the following get command syntax:

```
snmpget -v2c -c <community_name> <mgmt_address_ipv4> {<OID> | <MIB_field>}
```

where:

<community_name> is an SNMP community name added to the FortiGate configuration. You can add more than one community names to a FortiGate SNMP configuration. The most commonly used community name is public.

<mgmt_address_ipv4> is the IP address of the FortiGate HA reserved management interface that the SNMP manager connects to.

{<OID> | <MIB_field>} is the object identifier (OID) for the MIB field or the MIB field name itself. To find OIDs and MIB field names see your FortiGate's online help.

Adding FortiClient licenses to a cluster

Each FortiGate in a cluster must have its own FortiClient license. Contact your reseller to purchase FortiClient licenses for all of the FortiGates in your cluster.

When you receive the license keys you can visit the [Fortinet Support](#) website and add the FortiClient license keys to each FortiGate. Then, as long as the cluster can connect to the internet each cluster unit receives its FortiClient license key from the FortiGuard network.

Adding FortiClient licenses to cluster units with a reserved management interface

You can also use the following steps to manually add license keys to your cluster units from the GUI or CLI. Your cluster must be connected to the internet and you must have configured a reserved management interface for each cluster unit.

1. Log into the GUI of each cluster unit using its reserved management interface IP address.
2. Go to the **License Information** dashboard widget and beside **FortiClient** select **Enter License**.
3. Enter the license key and select **OK**.
4. Confirm that the license has been installed and the correct number of FortiClients are licensed.
5. Repeat for all of the cluster units.

You can also use the reserved management IP address to log into each cluster unit CLI and use following command to add the license key:

```
execute FortiClient-NAC update-registration-license <license-key>
```

You can connect to the CLIs of each cluster unit using their reserved management IP address.

Adding FortiClient licenses to cluster units with no reserved management interface

If you have not set up reserved management IP addresses for your cluster units, you can still add FortiClient license keys to each cluster unit. You must log into the primary unit and then use the `execute ha manage` command to connect to each cluster unit CLI. For example, use the following steps to add a FortiClient license key a cluster of three FortiGates:

1. Log into the primary unit CLI and enter the following command to confirm the serial number of the primary unit:

```
get system status
```

2. Add the FortiClient license key for that serial number to the primary unit:

```
execute FortiClient-NAC update-registration-license <license-key>
```

You can also use the GUI to add the license key to the primary unit.

3. Enter the following command to log into the first subordinate unit:

```
execute ha manage 1
```

4. Enter the following command to confirm the serial number of the cluster unit that you have logged into:

```
get system status
```

5. Add the FortiClient license key for that serial number to the cluster unit:

```
execute FortiClient-NAC update-registration-license <license-key>
```

6. Enter the following command to log into the second subordinate unit:

```
execute ha manage 2
```

7. Enter the following command to confirm the serial number of the cluster unit that you have logged into:

```
get system status
```

8. Add the FortiClient license key for that serial number to the cluster unit:

```
execute FortiClient-NAC update-registration-license <license-key>
```

Viewing FortiClient license status and active FortiClient users for each cluster unit

To view FortiClient license status and FortiClient information for each cluster unit you must log into each cluster unit's GUI or CLI. You can do this by connecting to each cluster unit's reserved management interface if they are configured. If you have not configured reserved management interfaces you can use the `execute ha manage` command to log into each cluster unit CLI.

From the GUI, view FortiClient License status from the License Information dashboard widget and select **Details** to display the list of active FortiClient users connecting through that cluster unit. You can also see active FortiClient users by going to **User & Device > Monitor > FortiClient**.

From the CLI you can use the `execute FortiClient {list | info}` command to display FortiClient license status and active FortiClient users.

For example, use the following command to display the FortiClient license status of the cluster unit that you are logged into:

```
execute forticlient info
Maximum FortiClient connections: unlimited.
Licensed connections: 114
  NAC: 114
  WANOPT: 0
  Test: 0
```

```
Other connections:
  IPsec: 0
  SSLVPN: 0
```

Use the following command to display the list of active FortiClient users connecting through the cluster unit. The output shows the time the connection was established, the type of FortiClient connection, the name of the device, the user name of the person connecting, the FortiClient ID, the host operating system, and the source IP address of the session.

```
execute forticlient list
TIMESTAMP TYPE CONNECT-NAME USER CLIENT-ID HOST-OS SRC-IP

```

Cluster members list

To display the cluster members list, go to **System > HA**.

The cluster members list displays illustrations of the front panels of the cluster units. If the network jack for an interface is shaded green, the interface is connected. Hover the mouse pointer over each illustration to view the cluster unit host name, serial number, and how long the unit has been operating (up time). The list of monitored interfaces is also displayed.

From the cluster members list you can:

- View HA statistics.
- Use the up and down arrows to change the order in which cluster units are listed.
- See the host name of each cluster unit. To change the primary unit host name, go to the system dashboard and select Change beside the current host name in the System Information widget. To view and change a subordinate unit host name, from the cluster members list select the edit icon for a subordinate unit.
- View the status or role of each cluster unit.
- View and optionally change the HA configuration of the operating cluster.
- View and optionally change the host name and device priority of a subordinate unit.
- Disconnect a cluster unit from a cluster.
- Download the Debug log for any cluster unit. You can send this debug log file to [Fortinet Support](#) to help diagnose problems with the cluster or with individual cluster units.

Virtual cluster members list

If virtual domains are enabled, you can display the cluster members list to view the status of the operating virtual clusters. The virtual cluster members list shows the status of both virtual clusters including the virtual domains added to each virtual cluster.

To display the virtual cluster members list for an operating cluster log in as the admin administrator, select Global Configuration and go to **System > HA**.

The functions of the virtual cluster members list are the same as the functions of the Cluster Members list with the following exceptions.

- When you select the edit icon for a primary unit in a virtual cluster, you can change the virtual cluster 1 and virtual cluster 2 device priority of this cluster unit and you can edit the VDOM partitioning configuration of the cluster.
- When you select the edit icon for a subordinate unit in a virtual cluster, you can change the device priority for the subordinate unit for the selected virtual cluster.

Also, the HA cluster members list changes depending on the cluster unit that you connect to.

Viewing HA statistics

From the cluster members list you can select **View HA statistics** to display the serial number, status, and monitor information for each cluster unit. To view HA statistics, go to **System > HA** and select View HA Statistics. Note the following about the HA statistics display:

- Use the serial number ID to identify each FortiGate in the cluster. The cluster ID matches the FortiGate serial number.
- Status indicates the status of each cluster unit. A green check mark indicates that the cluster unit is operating normally. A red X indicates that the cluster unit cannot communicate with the primary unit.
- The up time is the time in days, hours, minutes, and seconds since the cluster unit was last started.
- The GUI displays CPU usage for core processes only. CPU usage for management processes (for example, for HTTPS connections to the GUI) is excluded.
- The GUI displays memory usage for core processes only. Memory usage for management processes (for example, for HTTPS connections to the GUI) is excluded.

Changing the HA configuration of an operating cluster

To change the configuration settings of an operating cluster, go to **System > HA** to display the cluster members list. Select Edit for the master (or primary) unit in the cluster members list to display the HA configuration page for the cluster.

You can use the HA configuration page to check and fine tune the configuration of the cluster after the cluster is up and running. For example, if you connect or disconnect cluster interfaces you may want to change the Port Monitor configuration.

Any changes you make on this page, with the exception of changes to the device priority, are first made to the primary unit configuration and then synchronized to the subordinate units. Changing the device priority only affects the primary unit.

Changing the HA configuration of an operating virtual cluster

To change the configuration settings of the primary unit in a functioning cluster with virtual domains enabled, log in as the admin administrator, select Global Configuration and go to **System > HA** to display the cluster members list. Select Edit for the master (or primary) unit in virtual cluster 1 or virtual cluster 2 to display the HA configuration page for the virtual cluster.

You can use the virtual cluster HA configuration page to check and fine tune the configuration of both virtual clusters after the cluster is up and running. For example, you may want to change the Port Monitor configuration for virtual cluster 1 and virtual cluster 2 so that each virtual cluster monitors its own interfaces.

You can also use this configuration page to move virtual domains between virtual cluster 1 and virtual cluster 2. Usually you would distribute virtual domains between the two virtual clusters to balance the amount of traffic being processed by each virtual cluster.

Any changes you make on this page, with the exception of changes to the device priorities, are first made to the primary unit configuration and then synchronized to the subordinate unit.

You can also adjust device priorities to configure the role of this cluster unit in the virtual cluster. For example, to distribute traffic to both cluster units in the virtual cluster configuration, you would want one cluster unit to be the primary unit for virtual cluster 1 and the other cluster unit to be the primary unit for virtual cluster 2. You can create this configuration by setting the device priorities. The cluster unit with the highest device priority in virtual cluster 1 becomes the primary unit for virtual cluster 1. The cluster unit with the highest device priority in virtual cluster 2 becomes the primary unit in virtual cluster 2.

Changing the subordinate unit host name and device priority

To change the host name and device priority of a subordinate unit in an operating cluster, go to **System > HA** to display the cluster members list. Select Edit for any slave (subordinate) unit in the cluster members list.

To change the host name and device priority of a subordinate unit in an operating cluster with virtual domains enabled, log in as the admin administrator, select Global Configuration and go to **System > HA** to display the cluster members list. Select Edit for any slave (subordinate) unit in the cluster members list.

You can change the host name (Peer) and device priority (Priority) of this subordinate unit. These changes only affect the configuration of the subordinate unit.

The device priority is not synchronized among cluster members. In a functioning cluster you can change device priority to change the priority of any unit in the cluster. The next time the cluster negotiates, the cluster unit with the highest device priority becomes the primary unit.

The device priority range is 0 to 255. The default device priority is 128.

Upgrading cluster firmware

You can upgrade the FortiOS firmware running on an HA cluster in the same manner as upgrading the firmware running on a standalone FortiGate. During a normal firmware upgrade, the cluster upgrades the primary unit and all subordinate units to run the new firmware image. The firmware upgrade takes place without interrupting communication through the cluster.

Upgrading cluster firmware to a new major release (for example upgrading from 5.6.3 to 6.0.2) is supported for clusters. Make sure you are taking an appropriate [upgrade path](#). Even so you should back up your configuration and only perform such a firmware upgrade during a maintenance window.

To upgrade the firmware without interrupting communication through the cluster, the cluster goes through a series of steps that involve first upgrading the firmware running on the subordinate units, then making one of the subordinate units the primary unit, and finally upgrading the firmware on the former primary unit. These steps are transparent to the user and the network, but depending upon your HA configuration may result in the cluster selecting a new primary unit.

The following sequence describes in detail the steps the cluster goes through during a firmware upgrade and how different HA configuration settings may affect the outcome.

1. The administrator uploads a new firmware image from the GUI or CLI.
2. If the cluster is operating in active-active mode load balancing is turned off.
3. The cluster upgrades the firmware running on all of the subordinate units.
4. Once the subordinate units have been upgraded, a new primary unit is selected.

This primary unit will be running the new upgraded firmware.

5. The cluster now upgrades the firmware of the former primary unit.

If the age of the new primary unit is more than 300 seconds (5 minutes) greater than the age of all other cluster units, the new primary unit continues to operate as the primary unit.

This is the intended behavior but does not usually occur because the age difference of the cluster units is usually less than the cluster age difference margin of 300 seconds. So instead, the cluster negotiates again to select a primary unit as described in [Primary unit selection on page 1385](#).

You can keep the cluster from negotiating again by reducing the cluster age difference margin using the `ha-uptime-diff-margin` option. However, you should be cautious when reducing the age or other problems may occur. For information about the cluster age difference margin, see [Cluster age difference margin \(grace period\) on page 1388](#). For more information about changing the cluster age margin, see [Changing the cluster age difference margin on page 1388](#).

6. If the cluster is operating in active-active mode, load balancing is turned back on.

If, during the firmware upgrade process all of the subordinate units crash or otherwise stop responding, the primary unit will not be upgraded to the new firmware, but will continue to operate normally. The primary unit waits until at least one subordinate unit rejoins the cluster before upgrading its firmware.

Changing how the cluster processes firmware upgrades

By default cluster firmware upgrades proceed as uninterruptable upgrades that do not interrupt traffic flow. If required, you can use the following CLI command to change how the cluster handles firmware upgrades. You might want to change this setting if you are finding uninterruptable upgrades take too much time.

```
config system ha
    set uninterruptible-upgrade disable
end
```

`uninterruptible-upgrade` is enabled by default. If you disable `uninterruptible-upgrade` the cluster still upgrades the firmware on all cluster units, but all cluster units are upgraded at once; which takes less time but interrupts communication through the cluster.

Synchronizing the firmware build running on a new cluster unit

If the firmware build running on a FortiGate that you add to a cluster is older than the cluster firmware build, you may be able to use the following steps to synchronize the firmware running on the new cluster unit.

This procedure describes re-installing the same firmware build on a cluster to force the cluster to upgrade all cluster units to the same firmware build.

Due to firmware upgrade and synchronization issues, in some cases this procedure may not work. In all cases it will work to install the same firmware build on the new unit as the one that the cluster is running before adding the new unit to the cluster.

To synchronize the firmware build running on a new cluster unit

1. Obtain a firmware image that is the same as build already running on the cluster.
2. Connect to the cluster using the GUI.
3. Go to the **System Information** dashboard widget.
4. Select **Update** beside **Firmware Version**.

You can also install a newer firmware build.

5. Select **OK**.

After the firmware image is uploaded to the cluster, the primary unit upgrades all cluster units to this firmware build.

Downgrading cluster firmware

For various reasons you may need to downgrade the firmware that a cluster is running. You can use the information in this section to downgrade the firmware version running on a cluster.

In most cases you can downgrade the firmware on an operating cluster using the same steps as for a firmware upgrade. A warning message appears during the downgrade but the downgrade usually works and after the downgrade the cluster continues operating normally with the older firmware image.

Downgrading between some firmware versions, especially if features have changed between the two versions, may not always work without the requirement to fix configuration issues after the downgrade.

Only perform firmware downgrades during maintenance windows and make sure you back up your cluster configuration before the downgrade.

If the firmware downgrade that you are planning may not work without configuration loss or other problems, you can use the following downgrade procedure to make sure your configuration is not lost after the downgrade.

To downgrade cluster firmware

This example shows how to downgrade the cluster shown in Example NAT/Route mode HA network topology. The cluster consists of two cluster units (FGT_ha_1 and FGT_ha_2). The port1 and port2 interfaces are connected to networks and the port3 and port4 interfaces are connected together for the HA heartbeat.

This example, describes separating each unit from the cluster and downgrading the firmware for the standalone FortiGates. There are several ways you could disconnect units from the cluster. This example describes using the disconnect from cluster function on the cluster members list GUI page.

1. Go to the **System Information** dashboard widget and backup the cluster configuration.

From the CLI use `execute backup config`.

2. Go to **System > HA** and for FGT_ha_1 select the **Disconnect from cluster** icon.

3. Select the port2 interface and enter an IP address and netmask of 10.11.101.101/24 and select **OK**.

From the CLI you can enter the following command (FG600B3908600705 is the serial number of the cluster unit) to be able to manage the standalone FortiGate by connecting to the port2 interface with IP address and netmask 10.11.101.101/24.

```
execute ha disconnect FG600B3908600705 port2 10.11.101.101/24
```

After FGT_ha_1 is disconnected, FGT_ha_2 continues processing traffic.

4. Connect to the FGT_ha_1 GUI or CLI using IP address 10.11.101.101/24 and follow normal procedures to downgrade standalone FortiGate firmware.
5. When the downgrade is complete confirm that the configuration of 620_ha_1 is correct.
6. Set the HA mode of FGT_ha_2 to Standalone and follow normal procedures to downgrade standalone FortiGate firmware.

Network communication will be interrupted for a short time during the downgrade.

7. When the downgrade is complete confirm that the configuration of FGT_ha_2 is correct.
8. Set the HA mode of FGT_ha_2 to Active-Passive or the required HA mode.
9. Set the HA mode of FGT_ha_1 to the same mode as FGT_ha_2.
If you have not otherwise changed the HA settings of the cluster units and if the firmware downgrades have not affected the configurations the units should negotiate and form cluster running the downgraded firmware.

Backing up and restoring the cluster configuration

You can backup and restore the configuration of a cluster in the same way as backing up and restoring a standalone FortiGate unit. Backing up the cluster from the primary unit GUI or CLI saves a single configuration file for the cluster. If you restore this configuration file, the configuration of all cluster units is restored. The restore process keeps configuration settings of individual cluster units that are not synchronized unchanged but resets all other configuration setting to those in the restored configuration file.

When restoring the configuration of a cluster, all cluster units reboot to install the new configuration. This may result in a brief traffic interruption as all cluster units may restart at the same time.

Restoring settings that are not synchronized

The FGCP does not synchronize some FortiOS configuration settings. For details about settings that are not synchronized, see [Synchronizing the configuration \(and settings that are not synchronized\) on page 1376](#). If you need to restore the configuration of the cluster including the configuration settings that are not synchronized, you should first restore the configuration of the primary FortiGate and then restore the configuration of the other cluster units. Alternatively you could log into each FortiGate in the cluster and manually add the configuration settings that were not restored.

Monitoring cluster units for failover

If the primary unit in the cluster fails, the units in the cluster renegotiate to select a new primary unit. Failure of the primary unit results in the following:

- If SNMP is enabled, the new primary unit sends HA trap messages. The messages indicate a cluster status change, HA heartbeat failure, and HA member down.
- If event logging is enabled and HA activity event is selected, the new primary unit records log messages that show that the unit has become the primary unit.
- If alert email is configured to send email for HA activity events, the new primary unit sends an alert email containing the log message recorded by the event log.
- The cluster contains fewer FortiGates. The failed primary unit no longer appears on the Cluster Members list.
- The host name and serial number of the primary unit changes. You can see these changes when you log into the GUI or CLI.
- The cluster info displayed on the dashboard, cluster members list or from the `get system ha status` command changes.

If a subordinate unit fails, the cluster continues to function normally. Failure of a subordinate unit results in the following:

- If event logging is enabled and HA activity event is selected, the primary unit records log messages that show that a subordinate has been removed from the cluster.
- If alert email is configured to send email for HA activity events, the new primary unit sends an alert email containing the log message recorded by the event log.
- The cluster contains fewer FortiGates. The failed unit no longer appears on the Cluster Members list.

Viewing cluster status from the CLI

Use the `get system ha status` command to display information about an HA cluster. The command displays general HA configuration settings. The command also displays information about how the cluster unit that you have logged into is operating in the cluster. You can enter the `get system ha status` command from the primary or backup units. The output produced by the command is similar for each unit, it shows cluster data as well as data for the FortiGate that you are logged into.

For a virtual cluster configuration, the `get system ha status` command displays information about how the cluster unit that you have logged into is operating in virtual cluster 1 and virtual cluster 2. For example, if you connect to the cluster unit that is the primary unit for virtual cluster 1 and the subordinate unit for virtual cluster 2, the output of the `get system ha status` command shows virtual cluster 1 in the work state and virtual cluster 2 in the standby state. The `get system ha status` command also displays additional information about virtual cluster 1 and virtual cluster 2.

The command includes the following fields.

Field	Description
HA Health Status	Indicates if all cluster units are operating normally (OK) or if a problem was detected with the cluster. For example, a message similar to <code>ERROR <serial-number> is lost @ <date> <time></code> appears if one the subordinate units leaves the cluster.
Model	The FortiGate model number.
Mode	The HA mode of the cluster, for example, HA A-P or HA A-A.
Group	The group ID of the cluster.
Debug	The debug status of the cluster.
Cluster Uptime	The number of days, hours, minutes, and seconds that the cluster has been operating.
Cluster state changed time	The date and time at which the FortiGate most recently changed state. For example, the last time the FortiGate joined the cluster or changed from the primary unit to a backup unit, and so on.

Field	Description
Master selected using	Shows how the primary unit was selected the last four times that the cluster negotiated. For example, when a cluster first forms, this part of the command output could have one line showing that the primary unit is the cluster unit with the highest uptime. Up to four lines can be included as the cluster negotiates to choose a new primary unit on different occasions. Each line includes a time stamp and the criteria used to select the primary unit.
ses_pickup	The status of session pickup: enable or disable.
load_balance	The status of the <code>load-balance-all</code> keyword: enable or disable. Active-active clusters only.
load_balance_udp	The status of the <code>load-balance-udp</code> keyword: enable or disable. Available on some FortiGate models. Active-active clusters only.
schedule	The active-active load balancing schedule. Active-active clusters only.
override	The status of the override option for the current cluster unit: enable or disable.
Configuration Status	Shows if the configurations of each of the cluster units are synchronized or not.
System Usage stats	Shows how busy each cluster unit is by displaying the number of sessions being processed by the cluster unit, CPU usage, and memory usage.
HBDEV stats	Shows the status of each cluster unit's heartbeat interfaces. Includes whether the interfaces are up or down, how much data they have processed, as well as errors found.
Master Slave	<p>Displays the host name, serial number, and cluster index of the primary unit (master) and the subordinate units (slave). The FortiGate with cluster index 0 is the primary unit and the FortiGates with cluster indexes 1 to 3 are the backup units.</p> <p>The order in which the cluster units are listed starts with the cluster unit that you are logged into.</p>
number of vcluster	The number of virtual clusters. If virtual domains are not enabled, the cluster has one virtual cluster. If virtual domains are enabled the cluster has two virtual clusters.
vcluster 1 vcluster 2	The heartbeat interface IP address of the primary unit in each virtual cluster. If virtual domains are not enabled there is one vcluster and this is the IP address of the primary unit. If virtual domains are enabled then each vcluster line will have an IP address. If the IP addresses are the same then the same FortiGate is the primary unit for both virtual clusters.

Field	Description
<code>vcluster 1</code>	<p>The HA state (hello, work, or standby) and HA heartbeat IP address of the primary unit. If virtual domains are not enabled, <code>vcluster 1</code> displays information for the cluster. If virtual domains are enabled, <code>vcluster 1</code> displays information for virtual cluster 1.</p> <p><code>vcluster 1</code> also lists the primary unit (master) and subordinate units (slave) in virtual cluster 1. The list includes the serial number and operating cluster index of each cluster unit in virtual cluster 1. The cluster unit that you have logged into is at the top of the list. The FortiGate in the cluster with the highest serial number always has an operating cluster index of 0. Other FortiGates in the cluster get a higher operating cluster index based in their serial number. When you use the <code>execute ha manage</code> command to log into another FortiGate you use the operating cluster index to specify the FortiGate to log into.</p>
Master	<p>If virtual domains are not enabled and you connect to the primary unit CLI, the HA state of the cluster unit in virtual cluster 1 is work. The display lists the cluster units starting with the primary unit.</p>
Slave	<p>If virtual domains are not enabled and you connect to a subordinate unit CLI, the HA state of the cluster unit in virtual cluster 1 is standby. The display lists the cluster units starting with the subordinate unit that you have logged into.</p> <p>If virtual domains are enabled and you connect to the virtual cluster 1 primary unit CLI, the HA state of the cluster unit in virtual cluster 1 is work. The display lists the cluster units starting with the virtual cluster 1 primary unit.</p> <p>If virtual domains are enabled and you connect to the virtual cluster 1 subordinate unit CLI, the HA state of the cluster unit in virtual cluster 1 is standby. The display lists the cluster units starting with the subordinate unit that you are logged into.</p>
<code>vcluster 2</code>	<p><code>vcluster 2</code> only appears if virtual domains are enabled. <code>vcluster 2</code> displays the HA state (hello, work, or standby) and HA heartbeat IP address of the cluster unit that you have logged into in virtual cluster 2. The HA heartbeat IP address is 169.254.0.2 if you are logged into the primary unit of virtual cluster 2 and 169.254.0.1 if you are logged into a subordinate unit of virtual cluster 2.</p> <p><code>vcluster 2</code> also lists the primary unit (master) and subordinate units (slave) in virtual cluster 2. The list includes the cluster index and serial number of each cluster unit in virtual cluster 2. The cluster unit that you have logged into is at the top of the list.</p>
Master	<p>If you connect to the virtual cluster 2 primary unit CLI, the HA state of the cluster unit in virtual cluster 2 is <code>work</code>. The display lists the cluster units starting with the virtual cluster 2 primary unit.</p>
Slave	<p>If you connect to the virtual cluster 2 subordinate unit CLI, the HA state of the cluster unit in virtual cluster 2 is <code>standby</code>. The display lists the cluster units starting with the subordinate unit that you are logged into.</p>

Get system ha status example - two FortiGates in active-passive mode

The following example shows `get system ha status` output for a cluster of two FortiGate-600Ds operating in active-passive mode. The cluster is healthy and has been running for 3 hours and 26 minutes. Primary unit selection took place once and the cluster has been stable since then.

The following command output was produced by connecting to the primary unit CLI (host name Edge2-Primary).

```
get system ha status
HA Health Status: OK
Model: FortiGate-600D
Mode: HA A-P
Group: 25
Debug: 0
Cluster Uptime: 0 days 03:26:00
Cluster state change time: 2018-03-06 13:16:33
Master selected using:
    <2018/03/06 13:16:33> FGT6HD3916806098 is selected as the master because it has the
largest value of override priority.
    <2018/03/06 12:47:58> FGT6HD3916806070 is selected as the master because it has the
largest value of override priority.
    <2018/03/06 12:47:55> FGT6HD3916806098 is selected as the master because it has the
largest value of uptime.
    <2018/03/06 12:47:55> FGT6HD3916806098 is selected as the master because it's the only
member in the cluster.
ses_pickup: enable, ses_pickup_delay=disable
override: disable
Configuration Status:

```

About the HA operating cluster index and the execute ha manage command

When a cluster starts up, if primary unit select is based on serial number, the FortiGate Cluster Protocol (FGCP) assigns a cluster index and an HA heartbeat IP address to each cluster unit based on the serial number of the cluster unit:

- The FGCP selects the cluster unit with the highest serial number to become the primary unit. The FGCP assigns a cluster index of 0, an operating cluster index of 0, and an HA heartbeat IP address of 169.254.0.1 to this unit.

- The FGCP assigns a cluster index of 1, an operating cluster index of 1, and an HA heartbeat IP address of 169.254.0.2 to the cluster unit with the second highest serial number.
- If the cluster contains more units, the cluster unit with the third highest serial number is assigned a cluster index of 2, and operating cluster index of 2, and an HA heartbeat IP address of 169.254.0.3, and so on.

You can display the cluster index and operating cluster index assigned to each cluster unit using the `get system ha status` command. When you use the `execute ha manage` command you select a cluster unit to log into by entering its operating cluster index.

The operating cluster index and HA heartbeat IP address only change if a unit leaves the cluster or if a new unit joins the cluster. When one of these events happens, the FGCP resets the cluster index, operating cluster index, and HA heartbeat IP address of each cluster unit according to serial number in the same way as when the cluster first starts up.

If FortiGates don't leave or join, each cluster unit keeps its assigned operating cluster index, and HA heartbeat IP address since these are based on the FortiGate serial number, even as the units take on different roles in the cluster. After the operating cluster index and HA heartbeat IP addresses are set according to serial number, the FGCP checks other primary unit selection criteria such as device priority and monitored interfaces. Checking these criteria could result in selecting a cluster unit without the highest serial number to operate as the primary unit.

Even if the cluster unit without the highest serial number now becomes the primary unit, the operating cluster indexes and HA heartbeat IP addresses assigned to the individual cluster units do not change. Instead the FGCP changes the cluster index to reflect this role change. The cluster index is always 0 for the primary unit and 1 and higher for the other units in the cluster. By default both sets of cluster indexes are the same. But if primary unit selection selects the cluster unit that does not have the highest serial number to be the primary unit, then this cluster unit is assigned a cluster index of 0.

Using the `execute ha manage` command

When you use the CLI command `execute ha manage <index_integer>` to connect to the CLI of another cluster unit, the `<index_integer>` that you enter is the operating cluster index of the unit that you want to connect to.

Using `get system ha status` to display cluster indexes

You can display the cluster index assigned to each cluster unit using the CLI command `get system ha status`. The following example shows the information displayed by the `get system ha status` command for a cluster consisting of two FortiGates operating in active-passive HA mode with virtual domains not enabled and without virtual clustering.

```
get system ha status
.
.
.
Master: Edge2-Primary , FGT6HD3916806098, cluster index = 0
Slave : Edge2-Backup , FGT6HD3916806070, cluster index = 1
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master: FGT6HD3916806098, operating cluster index = 0
Slave : FGT6HD3916806070, operating cluster index = 1
```

In this example, the cluster unit with serial number FGT6HD3916806098 has the highest serial number and so has a cluster index and an operating cluster index of 0 and the cluster unit with serial number

FGT6HD3916806070 has a cluster index and an operating cluster index of 1. From the CLI of the primary unit of this cluster you can connect to the CLI of the subordinate unit using the following command:

```
execute ha manage 1
```

This works because the cluster unit with serial number FGT6HD3916806070 has a cluster index of 1.

The last three lines of the command output display the status of vcluster 1. In a cluster consisting of two cluster units operating without virtual domains enabled, all clustering actually takes place in virtual cluster 1. HA is designed to work this way to support virtual clustering. If this cluster was operating with virtual domains enabled, adding virtual cluster 2 is similar to adding a new copy of virtual cluster 1. Virtual cluster 2 is visible in the `get system ha status` command output when you add virtual domains to virtual cluster 2.

The HA heartbeat IP address displayed by the command is the HA heartbeat IP address of the cluster unit that is actually operating as the primary unit. For a default configuration, this IP address will always be 169.254.0.1 because the cluster unit with the highest serial number will be the primary unit. This IP address changes if the operating primary unit is not the primary unit with the highest serial number.

Example where the cluster index and operating cluster index do not match

This example shows `get system ha status` command output for the same cluster. However, in this example the device priority of the cluster unit with the serial number FGT6HD3916806098 is increased to 250. As a result the cluster unit with the lowest serial number becomes the primary unit. This means the cluster index and the operating cluster index of the cluster units do not match.

```
get system ha status
.
.
.
Master: Edge2-Primary , FGT6HD3916806098, cluster index = 1
Slave : Edge2-Backup , FGT6HD3916806070, cluster index = 0
number of vcluster: 1
vcluster 1: work 169.254.0.2
Master: FGT6HD3916806098, operating cluster index = 0
Slave : FGT6HD3916806070, operating cluster index = 1
```

The actual cluster indexes have not changed but the operating cluster indexes have. Also, the HA heartbeat IP address displayed for vcluster 1 has changed to 169.254.0.2.

Virtual clustering example output

The `get system ha status` command output is the same if a cluster is operating with virtual clustering turned on but with all virtual domains in virtual cluster 1. The following `get system ha status` command output example shows the same cluster operating as a virtual cluster with virtual domains in virtual cluster 1 and added to virtual cluster 2. In this example the cluster unit with serial number FG50012204400045 is the primary unit for virtual cluster 1 and the cluster unit with serial number FG50012205400050 is the primary unit for virtual cluster 2.

```
get system ha status
.
.
.
number of vcluster: 2
vcluster 1: work 169.254.0.2
Master: FG50012205400050, operating cluster index = 1
Slave : FG50012204400045, operating cluster index = 0
vcluster 2: standby 169.254.0.1
```

```
Master: FG50012205400050, operating cluster index = 0
```

```
Slave : FG50012204400045, operating cluster index = 1
```

This example shows three sets of indexes. The indexes in lines six and seven are still used by the `execute ha manage` command. The indexes on lines ten and eleven are for the primary and subordinate units in virtual cluster 1 and the indexes on the last two lines are for virtual cluster 2.

Managing individual cluster units

The following procedure describes how to use SSH to log into the primary unit CLI and from there to use the `execute ha manage` command to connect to the CLI of any other unit in the cluster. The procedure is very similar if you use telnet, or the GUI dashboard CLI console.

You can use the `execute ha manage` command from the CLI of any cluster unit to log into the CLI of another the cluster unit. Usually you would use this command from the CLI of the primary unit to log into the CLI of a subordinate unit. However, if you have logged into a subordinate unit CLI, you can use this command to log into the primary unit CLI, or the CLI of another subordinate unit.

Using SSH or telnet or the GUI CLI console you can only log into the primary unit CLI. Using a direct console connection you can log into any cluster unit. In both cases you can use `execute ha manage` to connect to the CLI of other cluster units.

1. Log into the primary unit CLI.

Connect to any cluster interface configured for SSH administrative access to log into the cluster.

2. Enter the following command followed by a space and type a question mark (?):

```
execute ha manage
```

The CLI displays a list of the serial numbers of all of the subordinate units in the cluster. Each cluster unit is numbered. The number is the operating cluster index.

3. Complete the command with the operating cluster index number of the subordinate unit to log into. For example, to log into subordinate unit 1, enter the following command:

```
execute ha manage 1
```

4. Log into the CLI of the selected subordinate unit.

The CLI prompt changes to the host name of the subordinate unit. You can use CLI commands to manage this subordinate unit. If you make changes to the configuration of any cluster unit (primary or subordinate unit) these changes are synchronized to all cluster units.

5. You can now use the `execute ha manage` command to connect to any other cluster unit (including the primary unit). You can also use the `exit` command to return to the primary unit CLI.

Disconnecting a cluster unit from a cluster

Use the following procedures to disconnect a cluster unit from a functioning cluster without disrupting the operation of the cluster. You can disconnect a cluster unit if you need to use the disconnected FortiGate for another purpose, such as to act as a standalone firewall.

You can use the following procedures for a standard cluster and for a virtual clustering configuration. To use the following procedures from a virtual cluster you must be logged in as the admin administrator and you must have selected Global Configuration.

When you disconnect a cluster unit you must assign an IP address and netmask to one of the interfaces of the disconnected unit. You can disconnect any unit from the cluster even the primary unit. After the unit is

disconnected, the cluster responds as if the disconnected unit has failed. The cluster may renegotiate and may select a new primary unit.

When the cluster unit is disconnected the HA mode is changed to standalone. In addition, all interface IP addresses of the disconnected unit are set to 0.0.0.0 except for the interface that you configure.

Otherwise the configuration of the disconnected unit is not changed. The HA configuration of the disconnected unit is not changed either (except to change the HA mode to Standalone).

To disconnect a cluster unit from a cluster - GUI

1. Go to **System > HA** to view the cluster members list.
2. Select the Disconnect from cluster icon for the cluster unit to disconnect from the cluster.
3. Select the interface that you want to configure. You also specify the IP address and netmask for this interface. When the FortiGate is disconnected, all management access options are enabled for this interface.
4. Specify an IP address and netmask for the interface. You can use this IP address to connect to the interface to configure the disconnected FortiGate.
5. Select **OK**.

The FortiGate is disconnected from the cluster and the cluster may renegotiate and select a new primary unit. The selected interface of the disconnected unit is configured with the specified IP address and netmask.

To disconnect a cluster unit from a cluster - CLI

1. Enter the following command to disconnect a cluster unit with serial number FGT5002803033050. The internal interface of the disconnected unit is set to IP address 1.1.1.1 and netmask 255.255.255.0

```
execute ha disconnect FGT5002803033050 internal 1.1.1.1 255.255.255.0
```

Adding a disconnected FortiGate back to its cluster

If you disconnect a FortiGate from a cluster, you can re-connect the disconnected FortiGate to the cluster by setting the HA mode of the disconnected unit to match the HA mode of the cluster. Usually the disconnected unit rejoins the cluster as a subordinate unit and the cluster automatically synchronizes its configuration.

You do not have to change the HA password on the disconnected unit unless the HA password has been changed after the unit was disconnected. Disconnecting a unit from a cluster does not change the HA password.

You should make sure that the device priority of the disconnected unit is lower than the device priority of the current primary unit. You should also make sure that the HA `override` CLI option is not enabled on the disconnected unit. Otherwise, when the disconnected unit joins the cluster, the cluster will renegotiate and the disconnected unit may become the primary unit. If this happens, the configuration of the disconnected unit is synchronized to all other cluster units. This configuration change might disrupt the operation of the cluster.

The following procedure assumes that the disconnected FortiGate is correctly physically connected to your network and to the cluster but is not running in HA mode and not part of the cluster.

Before you start this procedure you should note the device priority of the primary unit.

To add a disconnected FortiGate back to its cluster - GUI

1. Log into the disconnected FortiGate.
If virtual domains are enabled, log in as the admin administrator and select Global Configuration.
2. Go to **System > HA**.
3. Change Mode to match the mode of the cluster.
4. If required, change the group name and password to match the cluster.
5. Set the Device Priority lower than the device priority of the primary unit.
6. Select **OK**.
The disconnected FortiGate joins the cluster.

To add a disconnected FortiGate back to its cluster - CLI

1. Log into the CLI of the FortiGate to be added back to the cluster.
2. Enter the following command to access the global configuration and add the FortiGate back to a cluster operating in active-passive mode and set the device priority to 50 (a low number) so that this unit will not become the primary unit:

```
config global
  config system ha
    set mode a-p
    set priority 50
  end
end
```

You may have to also change the group name, group id and password. However if you have not changed these for the cluster or the FortiGate after it was disconnected from the cluster you should not have to adjust them now.

diagnose sys ha dump-by command

You can use the following diagnose command to display data about a cluster:

```
diagnose sys ha dump-by {group | vcluster | rcache | debug-zone | vdom | kernel | device}
```

kernel

This command displays the HA configuration stored by the kernel.

```
diagnose sys ha dump-by kernel
      HA information.
group_id=88, nvcluster=2, mode=2, load_balance=0, schedule=3, ldb_udp=0.
nvcluster=2, mode=2, ses_pickup=0, delay=0, load_balance=0
schedule=3, ldb_udp=0, standalone_ha=0, upgrade_mode=0.
vcluster 1:
FGT51E5618000206, 0, 0.
FGT51E5618000259, 1, 1.
vcluster 2:
FGT51E5618000206, 1, 1.
FGT51E5618000259, 0, 0.
```

HA and failover protection

In FortiGate active-passive HA, the FortiGate Clustering Protocol (FGCP) provides failover protection. This means that an active-passive cluster can provide FortiGate services even when one of the cluster units encounters a problem that would result in complete loss of connectivity for a stand-alone FortiGate. This failover protection provides a backup mechanism that can be used to reduce the risk of unexpected downtime, especially in a mission-critical environment.

The FGCP supports three kinds of failover protection. Device failover automatically replaces a failed device and restarts traffic flow with minimal impact on the network. Link failover maintains traffic flow if a link fails. Session failover resumes communication sessions with minimal loss of data if a device or link failover occurs.

This chapter describes how FGCP failover protection works and provides detailed NAT/Route and transparent mode packet flow descriptions.

About active-passive failover

To achieve failover protection in an active-passive cluster, one of the cluster units functions as the primary unit, while the rest of the cluster units are subordinate units, operating in an active stand-by mode. The cluster IP addresses and HA virtual MAC addresses are associated with the cluster interfaces of the primary unit. All traffic directed at the cluster is actually sent to and processed by the primary unit.

While the cluster is functioning, the primary unit functions as the FortiGate network security device for the networks that it is connected to. In addition, the primary unit and subordinate units use the HA heartbeat to keep in constant communication. The subordinate units report their status to the cluster unit and receive and store connection and state table updates.

Device failure

If the primary unit encounters a problem that is severe enough to cause it to fail, the remaining cluster units negotiate to select a new primary unit. This occurs because all of the subordinate units are constantly waiting to negotiate to become primary units. Only the heartbeat packets sent by the primary unit keep the subordinate units from becoming primary units. Each received heartbeat packet resets negotiation timers in the subordinate units. If this timer is allowed to run out because the subordinate units do not receive heartbeat packets from the primary unit, the subordinate units assume that the primary unit has failed, and negotiate to become primary units themselves.

Using the same FGCP negotiation process that occurs when the cluster starts up, after they determine that the primary unit has failed, the subordinate units negotiate amongst themselves to select a new primary unit. The subordinate unit that wins the negotiation becomes the new primary unit with the same MAC and IP addresses as the former primary unit. The new primary unit then sends gratuitous ARP packets out all of its interfaces to inform attached switches to send traffic to the new primary unit. Sessions then resume with the new primary unit.

Link failure

If a primary unit interface fails or is disconnected while a cluster is operation, a link failure occurs. When a link failure occurs the cluster units negotiate to select a new primary unit. Since the primary unit has not stopped operating, it participates in the negotiation. The link failure means that a new primary unit must be selected and the cluster unit with the link failure joins the cluster as a subordinate unit.

Just as for a device failover, the new primary unit sends gratuitous arp packets out all of its interfaces to inform attached switches to send traffic to it. Sessions then resume with the new primary unit.

If a subordinate unit experiences a device failure its status in the cluster does not change. However, in future negotiations a cluster unit with a link failure is unlikely to become the primary unit.

Session failover

If you enable session failover (also called session pickup) for the cluster, during cluster operation the primary unit informs the subordinate units of changes to the primary unit connection and state tables, keeping the subordinate units up-to-date with the traffic currently being processed by the cluster.

After a failover the new primary unit recognizes open sessions that were being handled by the cluster. The sessions continue to be processed by the new primary unit and are handled according to their last known state.

If you leave session pickup disabled, the cluster does not keep track of sessions and after a failover, active sessions have to be restarted or resumed.

Primary unit recovery

If a primary unit recovers after a device or link failure, it will operate as a subordinate unit, unless the `override` CLI keyword is enabled and its device priority is set higher than the unit priority of other cluster units (see [HA override on page 1393](#)).

About active-active failover

HA failover in a cluster running in active-active mode is similar to active-passive failover described above. Active-active subordinate units are constantly waiting to negotiate to become primary units and, if session failover is enabled, continuously receive connection state information from the primary unit. If the primary unit fails, or one of the primary unit interfaces fails, the cluster units use the same mechanisms to detect the failure and to negotiate to select a new primary unit. If session failover is enabled, the new primary unit also maintains communication sessions through the cluster using the shared connection state table.

Active-active HA load balances sessions among all cluster units. For session failover, the cluster must maintain all of these sessions. To load balance sessions, the functioning cluster uses a load balancing schedule to distribute sessions to all cluster units. The shared connection state table tracks the communication sessions being processed by all cluster units (not just the primary unit). After a failover, the new primary unit uses the load balancing schedule to re-distribute all of the communication sessions recorded in the shared connection state table among all of the remaining cluster units. The connections continue to be processed by the cluster, but possibly by a different cluster unit, and are handled according to their last known state.

Device failover

The FGCP provides transparent device failover. Device failover is a basic requirement of any highly available system. Device failover means that if a device fails, a replacement device automatically takes the place of the failed device and continues operating in the same manner as the failed device.

In the case of FortiOS HA, the device is the primary unit. If the primary unit fails, device failover ensures that one of the subordinate units in the cluster automatically takes the place of the primary unit and can continue processing network traffic in the same way as the failed primary unit.

Device failover does not maintain communication sessions. After a device failover, communication sessions have to be restarted. To maintain communication sessions, you must enable session failover. See [Device failover on page 1522](#).

FortiGate HA device failover is supported by the HA heartbeat, virtual MAC addresses, configuration synchronization, route synchronization and IPsec VPN SA synchronization.

The HA heartbeat makes sure that the subordinate units detect a primary unit failure. If the primary unit fails to respond on time to HA heartbeat packets the subordinate units assume that the primary unit has failed and negotiate to select a new primary unit.

The new primary unit takes the place of the failed primary unit and continues functioning in the same way as the failed primary unit. For the new primary unit to continue functioning like the failed primary unit, the new primary unit must be able to reconnect to network devices and the new primary unit must have the same configuration as the failed primary unit.

FortiGate HA uses virtual MAC addresses to reconnect the new primary unit to network devices. The FGCP causes the new primary unit interfaces to acquire the same virtual MAC addresses as the failed primary unit. As a result, the new primary unit has the same network identity as the failed primary unit.

The new primary unit interfaces have different physical connections than the failed primary unit. Both the failed and the new primary unit interfaces are connected to the same switches, but the new primary unit interfaces are connected to different ports on these switches. To make sure that the switches send packets to the new primary unit, the new primary unit interfaces send gratuitous ARP packets to the connected switches. These gratuitous ARP packets notify the switches that the primary unit MAC and IP addresses are on different switch ports and cause the switches to send packets to the ports connected to the new primary unit. In this way, the new primary unit continues to receive packets that would otherwise have been sent to the failed primary unit.

Configuration synchronization means that the new primary unit always has the same configuration as the failed primary unit. As a result the new primary unit operates in exactly the same way as the failed primary unit. If configuration synchronization were not available the new primary unit may not process network traffic in the same way as the failed primary unit.

Kernel routing table synchronization synchronizes the primary unit kernel routing table to all subordinate units so that after a failover the new primary unit does not have to form a completely new routing table. IPsec VPN SA synchronization synchronizes IPsec VPN security associations (SAs) and other IPsec session data so that after a failover the new primary unit can resume IPsec tunnels without having to establish new SAs.

HA heartbeat and communication between cluster units

The HA heartbeat keeps cluster units communicating with each other. The heartbeat consists of hello packets that are sent at regular intervals by the heartbeat interface of all cluster units. These hello packets describe the state of the cluster unit and are used by other cluster units to keep all cluster units synchronized.

HA heartbeat packets are non-TCP packets that use Ethertype values 0x8890, 0x8891, and 0x8893. The default time interval between HA heartbeats is 200 ms. The FGCP uses link-local IPv4 addresses in the 169.254.0.x range for HA heartbeat interface IP addresses.

For best results, isolate the heartbeat devices from your user networks by connecting the heartbeat devices to a separate switch that is not connected to any network. If the cluster consists of two FortiGates you can connect the heartbeat device interfaces directly using a crossover cable. Heartbeat packets contain sensitive information

about the cluster configuration. Heartbeat packets may also use a considerable amount of network bandwidth. For these reasons, it is preferable to isolate heartbeat packets from your user networks.

On startup, a FortiGate configured for HA operation broadcasts HA heartbeat hello packets from its HA heartbeat interface to find other FortiGates configured to operate in HA mode. If two or more FortiGates operating in HA mode connect with each other, they compare HA configurations (HA mode, HA password, and HA group ID). If the HA configurations match, the units negotiate to form a cluster.

While the cluster is operating, the HA heartbeat confirms that all cluster units are functioning normally. The heartbeat also reports the state of all cluster units, including the communication sessions that they are processing.

Heartbeat interfaces

A heartbeat interface is an Ethernet network interface in a cluster that is used by the FGCP for HA heartbeat communications between cluster units.

To change the HA heartbeat configuration go to **System > HA** and select the *FortiGate interfaces* to use as HA heartbeat interfaces.

Do not use a switch port for the HA heartbeat traffic. This configuration is not supported.

From the CLI enter the following command to make port4 and port5 HA heartbeat interfaces and give both interfaces a heartbeat priority of 150:

```
config system ha
    set hbdev port4 150 port5 150
end
```

The following example shows how to change the default heartbeat interface configuration so that the port4 and port1 interfaces can be used for HA heartbeat communication and to give the port4 interface the highest heartbeat priority so that port4 is the preferred HA heartbeat interface.

```
config system ha
    set hbdev port4 100 port1 50
end
```

By default, for most FortiGate models two interfaces are configured to be heartbeat interfaces. You can change the heartbeat interface configuration as required. For example you can select additional or different heartbeat interfaces. You can also select only one heartbeat interface.

In addition to selecting the heartbeat interfaces, you also set the **Priority** for each heartbeat interface. In all cases, the heartbeat interface with the highest priority is used for all HA heartbeat communication. If the interface fails or becomes disconnected, the selected heartbeat interface that has the next highest priority handles all heartbeat communication.

If more than one heartbeat interface has the same priority, the heartbeat interface with the highest priority that is also highest in the heartbeat interface list is used for all HA heartbeat communication. If this interface fails or becomes disconnected, the selected heartbeat interface with the highest priority that is next highest in the list handles all heartbeat communication.

The default heartbeat interface configuration sets the priority of two heartbeat interfaces to 50. You can accept the default heartbeat interface configuration if one or both of the default heartbeat interfaces are connected. You can select different heartbeat interfaces, select more heartbeat interfaces and change heartbeat priorities according to your requirements.

For the HA cluster to function correctly, you must select at least one heartbeat interface and this interface of all of the cluster units must be connected together. If heartbeat communication is interrupted and cannot failover to a second heartbeat interface, the cluster units will not be able to communicate with each other and more than one cluster unit may become a primary unit. As a result the cluster stops functioning normally because multiple devices on the network may be operating as primary units with the same IP and MAC addresses creating a kind of split brain scenario.

The heartbeat interface priority range is 0 to 512. The default priority when you select a new heartbeat interface is 0. The higher the number the higher the priority.

In most cases you can maintain the default heartbeat interface configuration as long as you can connect the heartbeat interfaces together. Configuring HA heartbeat interfaces is the same for virtual clustering and for standard HA clustering.

You can enable heartbeat communications for physical interfaces, but not for VLAN subinterfaces, IPsec VPN interfaces, redundant interfaces, or for 802.3ad aggregate interfaces. You cannot select these types of interfaces in the heartbeat interface list.

Selecting more heartbeat interfaces increases reliability. If a heartbeat interface fails or is disconnected, the HA heartbeat fails over to the next heartbeat interface.

You can select up to 8 heartbeat interfaces. This limit only applies to FortiGates with more than 8 physical interfaces.

HA heartbeat traffic can use a considerable amount of network bandwidth. If possible, enable HA heartbeat traffic on interfaces used only for HA heartbeat traffic or on interfaces connected to less busy networks.

Connecting HA heartbeat interfaces

For most FortiGate models if you do not change the heartbeat interface configuration, you can isolate the default heartbeat interfaces of all of the cluster units by connecting them all to the same switch. Use one switch per heartbeat interface. If the cluster consists of two units you can connect the heartbeat interfaces together using crossover cables.

HA heartbeat and data traffic are supported on the same cluster interface. In NAT/Route mode, if you decide to use heartbeat interfaces for processing network traffic or for a management connection, you can assign the interface any IP address. This IP address does not affect HA heartbeat traffic.

In transparent mode, you can connect the heartbeat interface to your network and enable management access. You would then establish a management connection to the interface using the transparent mode management IP address. This configuration does not affect HA heartbeat traffic.

Heartbeat packets and heartbeat interface selection

HA heartbeat hello packets are constantly sent by all of the enabled heartbeat interfaces. Using these hello packets, each cluster unit confirms that the other cluster units are still operating. The FGCP selects one of the heartbeat interfaces to be used for communication between the cluster units. The FGCP selects the heartbeat interface for heartbeat communication based on the linkfail states of the heartbeat interfaces, on the priority of the heartbeat interfaces, and on the interface index.

The FGCP checks the linkfail state of all heartbeat interfaces to determine which ones are connected. The FGCP selects one of these connected heartbeat interfaces to be the one used for heartbeat communication. The FGCP selects the connected heartbeat interface with the highest priority for heartbeat communication.

If more than one connected heartbeat interface has the highest priority the FGCP selects the heartbeat interface with the lowest interface index. The GUI lists the FortiGate interfaces in alphabetical order. This order corresponds to the interface index order with lowest index at the top and highest at the bottom. If more than one heartbeat interface has the highest priority, the FGCP selects the interface that is highest in the heartbeat interface list (or first in alphabetical order) for heartbeat communication.

If the interface that is processing heartbeat traffic fails or becomes disconnected, the FGCP uses the same criteria to select another heartbeat interface for heartbeat communication. If the original heartbeat interface is fixed or reconnected, the FGCP again selects this interface for heartbeat communication.

The HA heartbeat communicates cluster session information, synchronizes the cluster configuration, synchronizes the cluster kernel routing table, and reports individual cluster member status. The HA heartbeat constantly communicates HA status information to make sure that the cluster is operating properly.

Interface index and display order

The GUI and CLI display interface names in alphanumeric order. For example, the sort order for a FortiGate with 10 interfaces (named port1 through port10) places port10 at the bottom of the list:

- port1
- port2 through 9
- port10

However, interfaces are indexed in hash map order, rather than purely by alphabetic order or purely by interface number value comparisons. As a result, the list is sorted primarily alphabetical by interface name (for example, base1 is before port1), then secondarily by index numbers:

- port1
- port10
- port2 through port9

HA heartbeat interface IP addresses

The FGCP uses link-local IPv4 addresses ([RFC 3927](#)) in the 169.254.0.x range for HA heartbeat interface IP addresses and for inter-VDOM link interface IP addresses. When a cluster initially starts up, the primary unit heartbeat interface IP address is 169.254.0.1. Subordinate units are assigned heartbeat interface IP addresses in the range 169.254.0.2 to 169.254.0.63. HA inter-VDOM link interfaces on the primary unit are assigned IP addresses 169.254.0.65 and 169.254.0.66.

If a failover occurs, the primary unit heartbeat interface could be something other than 169.254.0.1. If for example, the first subordinate unit is now the primary unit, the primary unit heartbeat interface IP address would be 169.254.0.2.

The output from the `get system ha status` CLI command shows the HA heartbeat interface IP address of the primary unit.

```
get system ha status
.
.
.
vcluster 1: work 169.254.0.2
.
.
.
```

You can also use the `execute traceroute` command from the subordinate unit CLI to display HA heartbeat IP addresses and the HA inter-VDOM link IP addresses. For example, use `execute ha manage 1` to connect to the subordinate unit CLI and then enter the following command to trace the route to an IP address on your network:

```
execute traceroute 172.20.20.10
traceroute to 172.20.20.10 (172.20.20.10), 32 hops max, 72 byte packets
 1 169.254.0.1 0 ms 0 ms 0 ms
 2 169.254.0.66 0 ms 0 ms 0 ms
 3 172.20.20.10 0 ms 0 ms 0 ms
```

Both HA heartbeat and data traffic are supported on the same FortiGate interface. All heartbeat communication takes place on a separate VDOM called `vsys_ha`. Heartbeat traffic uses a virtual interface called `port_ha` in the `vsys_ha` VDOM. Data and heartbeat traffic use the same physical interface, but they're logically separated into separate VDOMs.

Heartbeat packet Ethertypes

Normal IP packets are 802.3 packets that have an Ethernet type (Ethertype) field value of 0x0800. Ether type values other than 0x0800 are understood as level 2 frames rather than IP packets.

By default, HA heartbeat packets use the following Ethertypes:

- HA heartbeat packets for NAT/Route mode clusters use Ether type 0x8890. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the Ether type of these packets using the `ha-eth-type` option of the `config system ha` command.
- HA heartbeat packets for transparent mode clusters use Ether type 0x8891. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the Ether type of these packets using the `hc-eth-type` option of the `config system ha` command.
- HA telnet sessions between cluster units over HA heartbeat links use Ether type 0x8893. The telnet sessions allow an administrator to connect between FortiGates in the cluster using the `execute ha manage` command. You can change the Ether type of these packets using the `l2ep-eth-type` option of the `config system ha` command.

Because heartbeat packets are recognized as level 2 frames, the switches and routers on your heartbeat network that connect to heartbeat interfaces must be configured to allow them. If level2 frames are dropped by these network devices, heartbeat traffic will not be allowed between the cluster units.

Some third-party network equipment may use packets with these Ethertypes for other purposes. For example, Cisco N5K/Nexus switches use Ether type 0x8890 for some functions. When one of these switches receives Ether type 0x8890 packets from an attached cluster unit, the switch generates CRC errors and the packets are not forwarded. As a result, FortiGates connected with these switches cannot form a cluster.

In some cases, if the heartbeat interfaces are connected and configured so regular traffic flows but heartbeat traffic is not forwarded, you can change the configuration of the switch that connects the HA heartbeat interfaces to allow level2 frames with Ethertypes 0x8890, 0x8891, and 0x8893 to pass.

Alternatively, you can use the following CLI options to change the Ethertypes of the HA heartbeat packets:

```
config system ha
  set ha-eth-type <ha_ethertype_4-digit_hex>
  set hc-eth-type <hc_ethertype_4-digit_hex>
  set l2ep-eth-type <l2ep_ethertype_4-digit_hex>
end
```

For example, use the following command to change the Ether type of the HA heartbeat packets from 0x8890 to 0x8895 and to change the Ether type of HA Telnet session packets from 0x8891 to 0x889f:

```
config system ha
    set ha-eth-type 8895
    set l2ep-eth-type 889f
end
```

Modifying heartbeat timing

In an HA cluster, if a cluster unit CPU becomes very busy, the cluster unit may not be able to send heartbeat packets on time. If heartbeat packets are not sent on time other units in the cluster may think that the cluster unit has failed and the cluster will experience a failover.

A cluster unit CPU may become very busy if the cluster is subject to a syn flood attack, if network traffic is very heavy, or for other similar reasons. You can use the following CLI commands to configure how the cluster times HA heartbeat packets:

```
config system ha
    set hb-interval <interval_integer>
    set hb-lost-threshold <threshold_integer>
    set hello-holddown <holddown_integer>
end
```

Changing the lost heartbeat threshold

The lost heartbeat threshold is the number of consecutive heartbeat packets that are not received from another cluster unit before assuming that the cluster unit has failed. The default value is 6, meaning that if the 6 heartbeat packets are not received from a cluster unit then that cluster unit is considered to have failed. The range is 1 to 60 packets.

If the primary unit does not receive a heartbeat packet from a subordinate unit before the heartbeat threshold expires, the primary unit assumes that the subordinate unit has failed.

If a subordinate unit does not receive a heartbeat packet from the primary unit before the heartbeat threshold expires, the subordinate unit assumes that the primary unit has failed. The subordinate unit then begins negotiating to become the new primary unit.

The lower the `hb-lost-threshold` the faster a cluster responds when a unit fails. However, sometimes heartbeat packets may not be sent because a cluster unit is very busy. This can lead to a false positive failure detection. To reduce these false positives you can increase the `hb-lost-threshold`.

Use the following CLI command to increase the lost heartbeat threshold to 12:

```
config system ha
    set hb-lost-threshold 12
end
```

Changing the heartbeat interval

The heartbeat interval is the time between sending HA heartbeat packets. The heartbeat interval range is 1 to 20 (100*ms). The heartbeat interval default is 2 (200 ms).

A heartbeat interval of 2 means the time between heartbeat packets is 200 ms. Changing the heartbeat interval to 5 changes the time between heartbeat packets to 500 ms (5 * 100ms = 500ms).

The HA heartbeat packets consume more bandwidth if the heartbeat interval is short. But if the heartbeat interval is very long, the cluster is not as sensitive to topology and other network changes.

Use the following CLI command to increase the heartbeat interval to 10:

```
config system ha
    set hb-interval 10
end
```

The heartbeat interval combines with the lost heartbeat threshold to set how long a cluster unit waits before assuming that another cluster unit has failed and is no longer sending heartbeat packets. By default, if a cluster unit does not receive a heartbeat packet from a cluster unit for $6 * 200 = 1200$ milliseconds or 1.2 seconds the cluster unit assumes that the other cluster unit has failed.

You can increase both the heartbeat interval and the lost heartbeat threshold to reduce false positives. For example, increasing the heartbeat interval to 20 and the lost heartbeat threshold to 30 means a failure will be assumed if no heartbeat packets are received after $30 * 2000$ milliseconds = 60,000 milliseconds, or 60 seconds.

Use the following CLI command to increase the heartbeat interval to 20 and the lost heartbeat threshold to 30:

```
config system ha
    set hb-lost-threshold 30
    set hb-interval 20
end
```

Changing the time to wait in the hello state

The hello state hold-down time is the number of seconds that a cluster unit waits before changing from hello state to work state. After a failure or when starting up, cluster units operate in the hello state to send and receive heartbeat packets so that all the cluster units can find each other and form a cluster. A cluster unit should change from the hello state to work state after it finds all of the other FortiGate units to form a cluster with. If for some reason all cluster units cannot find each other during the hello state then some cluster units may be joining the cluster after it has formed. This can cause disruptions to the cluster and affect how it operates.

One reason for a delay in all of the cluster units joining the cluster could be the cluster units are located at different sites or if for some other reason communication is delayed between the heartbeat interfaces.

If cluster units are joining your cluster after it has started up or if it takes a while for units to join the cluster you can increase the time that the cluster units wait in the hello state. The hello state hold-down time range is 5 to 300 seconds. The hello state hold-down time default is 20 seconds.

Use the following CLI command to increase the time to wait in the hello state to 1 minute (60 seconds):

```
config system ha
    set hello-holddown 60
end
```

Enabling or disabling HA heartbeat encryption and authentication

You can enable HA heartbeat encryption and authentication to encrypt and authenticate HA heartbeat packets. HA heartbeat packets should be encrypted and authenticated if the cluster interfaces that send HA heartbeat packets are also connected to your networks.

If HA heartbeat packets are not encrypted the cluster password and changes to the cluster configuration could be exposed and an attacker may be able to sniff HA packets to get cluster information. Enabling HA heartbeat message authentication prevents an attacker from creating false HA heartbeat messages. False HA heartbeat messages could affect the stability of the cluster.

HA heartbeat encryption and authentication are disabled by default. Enabling HA encryption and authentication could reduce cluster performance. Use the following CLI command to enable HA heartbeat encryption and authentication.

```
config system ha
```

```
set authentication enable
set encryption enable
end
```

HA authentication and encryption uses AES-128 for encryption and SHA1 for authentication.

Heartbeat bandwidth requirements

The majority of the traffic processed by the HA heartbeat interface is session synchronization traffic. Other heartbeat interface traffic required to synchronize IPsec state/keys, routing tables, configuration changes, and so on is usually negligible.

The amount of traffic required for session synchronization depends on the connections per second (CPS) that the cluster is processing since only new sessions (and session table updates) need to be synchronized.

Another factor to consider is that if session pickup is enabled, traffic on the heartbeat interface surges during a failover or when a unit joins or re-joins the cluster. When one of these events happens, the whole session table needs to be synchronized. Lower bandwidth HA heartbeat interfaces may increase failover time if they can't handle the higher demand during these events.

You can also reduce the amount of heartbeat traffic by:

- Turning off session pickup if you don't need it,
- Configuring `session-pickup-delay` to reduce the number of sessions that are synchronized,
- Using the `session-sync-dev` option to move session synchronization traffic off of the heartbeat link.

See [Improving session synchronization performance on page 1](#) for details.

Cluster virtual MAC addresses

When a cluster is operating, the FGCP assigns virtual MAC addresses to each primary unit interface. HA uses virtual MAC addresses so that if a failover occurs, the new primary unit interfaces will have the same virtual MAC addresses and IP addresses as the failed primary unit. As a result, most network equipment would identify the new primary unit as the exact same device as the failed primary unit.

If the MAC addresses changed after a failover, the network would take longer to recover because all attached network devices would have to learn the new MAC addresses before they could communicate with the cluster.

If a cluster is operating in NAT/Route mode, the FGCP assigns a different virtual MAC address to each primary unit interface. VLAN subinterfaces are assigned the same virtual MAC address as the physical interface that the VLAN subinterface is added to. Redundant interfaces or 802.3ad aggregate interfaces are assigned the virtual MAC address of the first interface in the redundant or aggregate list.

If a cluster is operating in transparent mode, the FGCP assigns a virtual MAC address for the primary unit management IP address. Since you can connect to the management IP address from any interface, all of the FortiGate interfaces appear to have the same virtual MAC address.

A MAC address conflict can occur if two clusters are operating on the same network. See [Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain on page 1535](#) for more information.

Subordinate unit MAC addresses do not change. You can verify this by connecting to the subordinate unit CLI and using the `get hardware interface nic` command to display the MAC addresses of each FortiGate interface.

The MAC address of a reserved management interface is not changed to a virtual MAC address. Instead the reserved management interface keeps its original MAC address.

When the new primary unit is selected after a failover, the primary unit sends gratuitous ARP packets to update the devices connected to the cluster interfaces (usually layer-2 switches) with the virtual MAC address. Gratuitous ARP packets configure connected network devices to associate the cluster virtual MAC addresses and cluster IP address with primary unit physical interfaces and with the layer-2 switch physical interfaces. This is sometimes called using gratuitous ARP packets (sometimes called GARP packets) to train the network. The gratuitous ARP packets sent from the primary unit are intended to make sure that the layer-2 switch forwarding databases (FDBs) are updated as quickly as possible.

Sending gratuitous ARP packets is not required for routers and hosts on the network because the new primary unit will have the same MAC and IP addresses as the failed primary unit. However, since the new primary unit interfaces are connected to different switch interfaces than the failed primary unit, many network switches will update their FDBs more quickly after a failover if the new primary unit sends gratuitous ARP packets.

Changing how the primary unit sends gratuitous ARP packets after a failover

When a failover occurs it is important that the devices connected to the primary unit update their FDBs as quickly as possible to reestablish traffic forwarding.

Depending on your network configuration, you may be able to change the number of gratuitous ARP packets and the time interval between ARP packets to reduce the cluster failover time.

You cannot disable sending gratuitous ARP packets, but you can use the following command to change the number of packets that are sent. For example, enter the following command to send 20 gratuitous ARP packets:

```
config system ha
    set arps 20
end
```

You can use this command to configure the primary unit to send from 1 to 60 ARP packets. Usually you would not change the default setting of 5. In some cases, however, you might want to reduce the number of gratuitous ARP packets. For example, if your cluster has a large number of VLAN interfaces and virtual domains and because gratuitous ARP packets are broadcast, sending a higher number gratuitous ARP packets may generate a lot of network traffic. As long as the cluster still fails over successfully, you could reduce the number of gratuitous ARP packets that are sent to reduce the amount of traffic produced after a failover.

If failover is taking longer than expected, you may be able to reduce the failover time by increasing the number of gratuitous ARP packets sent.

You can also use the following command to change the time interval in seconds between gratuitous ARP packets. For example, enter the following command to change the time between ARP packets to 3 seconds:

```
config system ha
    set arps-interval 3
end
```

The time interval can be in the range of 1 to 20 seconds. The default is 8 seconds between gratuitous ARP packets. Normally you would not need to change the time interval. However, you could decrease the time to be able to send more packets in less time if your cluster takes a long time to failover.

There may also be a number of reasons to set the interval higher. For example, if your cluster has a large number of VLAN interfaces and virtual domains and because gratuitous ARP packets are broadcast, sending gratuitous

ARP packets may generate a lot of network traffic. As long as the cluster still fails over successfully you could increase the interval to reduce the amount of traffic produced after a failover.

For more information about gratuitous ARP packets see [RFC 826](#) and [RFC 3927](#).

Disabling gratuitous ARP packets after a failover

You can use the following command to turn off sending gratuitous ARP packets after a failover:

```
config system ha
    set gratuitous-arps disable
end
```

Sending gratuitous ARP packets is turned on by default.

In most cases you would want to send gratuitous ARP packets because its a reliable way for the cluster to notify the network to send traffic to the new primary unit. However, in some cases, sending gratuitous ARP packets may be less optimal. For example, if you have a cluster of FortiGates in transparent mode, after a failover the new primary unit will send gratuitous ARP packets to all of the addresses in its Forwarding Database (FDB). If the FDB has a large number of addresses it may take extra time to send all the packets and the sudden burst of traffic could disrupt the network.

If you choose to disable sending gratuitous ARP packets you must first enable the `link-failed-signal` setting. The cluster must have some way of informing attached network devices that a failover has occurred.

For more information about the `link-failed-signal` setting, see [Updating MAC forwarding tables when a link failover occurs on page 1553](#).

How the virtual MAC address is determined

The virtual MAC address is determined based on following formula:

$$00-09-0f-09- <group-id_hex> - (<vcluster_integer> + <idx>)$$

where

`<group-id_hex>` is the HA Group ID for the cluster converted to hexadecimal. The following table lists the virtual MAC address set for each group ID.

HA group ID in integer and hexadecimal format

Integer Group ID	Hexadecimal Group ID
0	00
1	01
2	02
3	03
4	04
...	...

Integer Group ID	Hexadecimal Group ID
10	0a
11	0b
...	...
63	3f
...	...
255	ff

`<vcluster_integer>` is 0 for virtual cluster 1 and 20 for virtual cluster 2. If virtual domains are not enabled, HA sets the virtual cluster to 1 and by default all interfaces are in the root virtual domain. Including virtual cluster and virtual domain factors in the virtual MAC address formula means that the same formula can be used whether or not virtual domains and virtual clustering is enabled.

`<idx>` is the index number of the interface. Interfaces are numbered from 0 to x (where x is the number of interfaces). Interfaces are numbered according to their has map order. See [Interface index and display order on page 1526](#). The first interface has an index of 0. The second interface in the list has an index of 1 and so on.

Only the `<idx>` part of the virtual MAC address is different for each interface. The `<vcluster_integer>` would be different for different interfaces if multiple VDOMs have been added.

Between FortiOS releases interface indexing may change so the virtual MAC addresses assigned to individual FortiGate interfaces may also change.

Example virtual MAC addresses

An HA cluster with HA group ID unchanged (default=0) and virtual domains not enabled would have the following virtual MAC addresses for interfaces port1 to port12:

- port1 virtual MAC: 00-09-0f-09-00-00
- port10 virtual MAC: 00-09-0f-09-00-01
- port2 virtual MAC: 00-09-0f-09-00-02
- port3 virtual MAC: 00-09-0f-09-00-03
- port4 virtual MAC: 00-09-0f-09-00-04
- port5 virtual MAC: 00-09-0f-09-00-05
- port6 virtual MAC: 00-09-0f-09-00-06
- port7 virtual MAC: 00-09-0f-09-00-07
- port8 virtual MAC: 00-09-0f-09-00-08
- port9 virtual MAC: 00-09-0f-09-00-

- port11 virtual MAC: 00-09-0f-09-00-0a
- port12 virtual MAC: 00-09-0f-09-00-0b

If the group ID is changed to 34 these virtual MAC addresses change to:

- port1 virtual MAC: 00-09-0f-09-22-00
- port3 virtual MAC: 00-09-0f-09-22-03
- port4 virtual MAC: 00-09-0f-09-22-04
- port5 virtual MAC: 00-09-0f-09-22-05
- port6 virtual MAC: 00-09-0f-09-22-06
- port7 virtual MAC: 00-09-0f-09-22-07
- port8 virtual MAC: 00-09-0f-09-22-08
- port9 virtual MAC: 00-09-0f-09-22-
- port11 virtual MAC: 00-09-0f-09-22-0a
- port12 virtual MAC: 00-09-0f-09-22-0b
- port10 virtual MAC: 00-09-0f-09-22-01
- port2 virtual MAC: 00-09-0f-09-22-02

A cluster with virtual domains enabled where the HA group ID has been changed to 23, port5 and port 6 are in the root virtual domain (which is in virtual cluster1), and port7 and port8 are in the vdom_1 virtual domain (which is in virtual cluster 2) would have the following virtual MAC addresses:

- port5 interface virtual MAC: 00-09-0f-09-23-05
- port6 interface virtual MAC: 00-09-0f-09-23-06
- port7 interface virtual MAC: 00-09-0f-09-23-27
- port8 interface virtual MAC: 00-09-0f-09-23-28

Displaying the virtual MAC address

Every FortiGate physical interface has two MAC addresses: the current hardware address and the permanent hardware address. The permanent hardware address cannot be changed, it is the actual MAC address of the interface hardware. The current hardware address can be changed. The current hardware address is the address seen by the network. For a FortiGate not operating in HA, you can use the following command to change the current hardware address of the port1 interface:

```
config system interface
  edit port1
    set macaddr <mac_address>
  end
end
```

For an operating cluster, the current hardware address of each cluster unit interface is changed to the HA virtual MAC address by the FGCP. The `macaddr` option is not available for a functioning cluster. You cannot change an interface MAC address and you cannot view MAC addresses from the `system interface` CLI command.

You can use the `get hardware nic <interface_name_str>` command to display both MAC addresses for any FortiGate interface. This command displays hardware information for the specified interface. Depending on their hardware configuration, this command may display different information for different interfaces. You can use this command to display the current hardware address as `Current_HWaddr` and the permanent hardware address as `Permanent_HWaddr`. For some interfaces the current hardware address is displayed as `MAC`. The command displays a great deal of information about the interface so you may have to scroll the output to find the hardware addresses.

You can also use the `diagnose hardware deviceinfo nic <interface_str>` command to display both MAC addresses for any FortiGate interface.

Before HA configuration the current and permanent hardware addresses are the same. For example for one of the units in Cluster_1:

```
FGT60B3907503171 # get hardware nic internal
.
.
.
MAC: 02:09:0f:78:18:c9
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

During HA operation the current hardware address becomes the HA virtual MAC address, for example for the units in Cluster_1:

```
FGT60B3907503171 # get hardware nic internal
.
.
.
MAC: 00:09:0f:09:00:02
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

The following command output for Cluster_2 shows the same current hardware address for port1 as for the internal interface of Cluster_2, indicating a MAC address conflict.

```
FG300A2904500238 # get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:02
Permanent_HWaddr: 00:09:0F:85:40:FD
.
.
.
```

Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain

A network may experience packet loss when two FortiGate HA clusters have been deployed in the same broadcast domain. Deploying two HA clusters in the same broadcast domain can result in packet loss because of MAC address conflicts. The packet loss can be diagnosed by pinging from one cluster to the other or by pinging both of the clusters from a device within the broadcast domain. You can resolve the MAC address conflict by changing the HA Group ID configuration of the two clusters. The HA Group ID is sometimes also called the Cluster ID.

This section describes a topology that can result in packet loss, how to determine if packets are being lost, and how to correct the problem by changing the HA Group ID.

Packet loss on a network can also be caused by IP address conflicts. Finding and fixing IP address conflicts can be difficult. However, if you are experiencing packet loss and your network contains two FortiGate HA clusters you can use the information in this article to eliminate one possible source of packet loss.

Changing the HA group ID to avoid MAC address conflicts

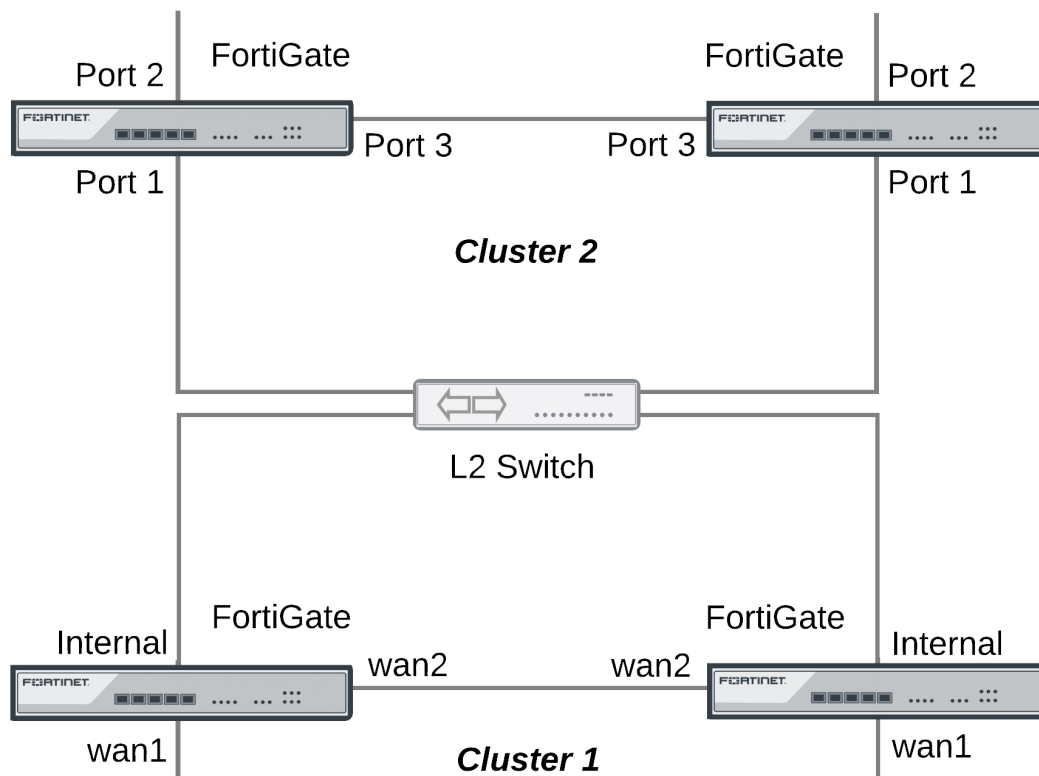

Change the Group ID to change the virtual MAC address of all cluster interfaces. You can change the Group ID from the FortiGate CLI using the following command:

```
config system ha
    set group-id <id_integer>
end
```

Example topology

The topology below shows two clusters. The Cluster_1 internal interfaces and the Cluster_2 port 1 interfaces are both connected to the same broadcast domain. In this topology the broadcast domain could be an internal network. Both clusters could also be connected to the internet or to different networks.

Example HA topology with possible MAC address conflicts

Ping testing for packet loss

If the network is experiencing packet loss, it is possible that you will not notice a problem unless you are constantly pinging both HA clusters. During normal operation of the network you also might not notice packet loss because the loss rate may not be severe enough to timeout TCP sessions. Also many common types of TCP traffic, such as web browsing, may not be greatly affected by packet loss. However, packet loss can have a significant effect on real time protocols that deliver audio and video data.

To test for packet loss you can set up two constant ping sessions, one to each cluster. If packet loss is occurring the two ping sessions should show alternating replies and timeouts from each cluster.

Cluster_1	Cluster_2
reply	timeout
reply	timeout
reply	timeout
timeout	reply
timeout	reply
reply	timeout
reply	timeout
timeout	reply
timeout	reply
timeout	reply
timeout	reply

Viewing MAC address conflicts on attached switches

If two HA clusters with the same virtual MAC address are connected to the same broadcast domain (L2 switch or hub), the MAC address will conflict and bounce between the two clusters. This example Cisco switch MAC address table shows the MAC address flapping between different interfaces (1/0/1 and 1/0/4).

```
1 0009.0f09.0002 DYNAMIC Gi1/0/1
1 0009.0f09.0002 DYNAMIC Gi1/0/4
```

Synchronizing the configuration

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit.

The following settings are not synchronized between cluster units:

- HA override.
- HA device priority.

- The virtual cluster priority.
- The FortiGate host name.
- The HA priority setting for a ping server (or dead gateway detection) configuration.
- The system interface settings of the HA reserved management interface.
- The HA default route for the reserved management interface, set using the `ha-mgmt-interface-gateway` option of the `config system ha` command.

The primary unit synchronizes all other configuration settings, including the other HA configuration settings.

All synchronization activity takes place over the HA heartbeat link using TCP/703 and UDP/703 packets.

Disabling automatic configuration synchronization

In some cases you may want to use the following command to disable automatic synchronization of the primary unit configuration to all cluster units.

```
config system ha
    set sync-config disable
end
```

When this option is disabled the cluster no longer synchronizes configuration changes. If a device failure occurs, the new primary unit may not have the same configuration as the failed primary unit. As a result, the new primary unit may process sessions differently or may not function on the network in the same way.

In most cases you should not disable automatic configuration synchronization. However, if you have disabled this feature you can use the `execute ha synchronize` command to manually synchronize a subordinate unit's configuration to that of the primary unit.

You must enter `execute ha synchronize` commands from the subordinate unit that you want to synchronize with the primary unit. Use the `execute ha manage` command to access a subordinate unit CLI.

For example, to access the first subordinate unit and force a synchronization at any time, even if automatic synchronization is disabled enter:

```
execute ha manage 0
execute ha synchronize start
```

You can use the following command to stop a synchronization that is in progress.

```
execute ha synchronize stop
```

Incremental synchronization

When you log into the cluster GUI or CLI to make configuration changes, you are actually logging into the primary unit. All of your configuration changes are first made to the primary unit. Incremental synchronization then immediately synchronizes these changes to all of the subordinate units.

When you log into a subordinate unit CLI (for example using `execute ha manage`) all of the configuration changes that you make to the subordinate unit are also immediately synchronized to all cluster units, including the primary unit, using the same process.

Incremental synchronization also synchronizes other dynamic configuration information such as the DHCP server address lease database, routing table updates, IPsec SAs, MAC address tables, and so on. See [FortiGate HA compatibility with DHCP and PPPoE on page 1397](#) for more information about DHCP server address lease synchronization and [Synchronizing kernel routing tables on page 1546](#) for information about routing table updates.

Whenever a change is made to a cluster unit configuration, incremental synchronization sends the same configuration change to all other cluster units over the HA heartbeat link. An HA synchronization process running on the each cluster unit receives the configuration change and applies it to the cluster unit. The HA synchronization process makes the configuration change by entering a CLI command that appears to be entered by the administrator who made the configuration change in the first place.

Synchronization takes place silently, and no log messages are recorded about the synchronization activity. However, log messages can be recorded by the cluster units when the synchronization process enters CLI commands. You can see these log messages on the subordinate units if you enable event logging and set the minimum severity level to **Information** and then check the event log messages written by the cluster units when you make a configuration change.

You can also see these log messages on the primary unit if you make configuration changes from a subordinate unit.

Periodic synchronization

Incremental synchronization makes sure that as an administrator makes configuration changes, the configurations of all cluster units remain the same. However, a number of factors could cause one or more cluster units to go out of sync with the primary unit. For example, if you add a new unit to a functioning cluster, the configuration of this new unit will not match the configuration of the other cluster units. Its not practical to use incremental synchronization to change the configuration of the new unit.

Periodic synchronization is a mechanism that looks for synchronization problems and fixes them. Every minute the cluster compares the configuration file checksum of the primary unit with the configuration file checksums of each of the subordinate units. If all subordinate unit checksums are the same as the primary unit checksum, all cluster units are considered synchronized.

If one or more of the subordinate unit checksums is not the same as the primary unit checksum, the subordinate unit configuration is considered out of sync with the primary unit. The checksum of the out of sync subordinate unit is checked again every 15 seconds. This re-checking occurs in case the configurations are out of sync because an incremental configuration sequence has not completed. If the checksums do not match after 5 checks the subordinate unit that is out of sync retrieves the configuration from the primary unit. The subordinate unit then reloads its configuration and resumes operating as a subordinate unit with the same configuration as the primary unit.

The configuration of the subordinate unit is reset in this way because when a subordinate unit configuration gets out of sync with the primary unit configuration there is no efficient way to determine what the configuration differences are and to correct them. Resetting the subordinate unit configuration becomes the most efficient way to resynchronize the subordinate unit.

Synchronization requires that all cluster units run the same FortiOS firmware build. If some cluster units are running different firmware builds, then unstable cluster operation may occur and the cluster units may not be able to synchronize correctly.

Re-installing the firmware build running on the primary unit forces the primary unit to upgrade all cluster units to the same firmware build.

Console messages when configuration synchronization succeeds

When a cluster first forms, or when a new unit is added to a cluster as a subordinate unit, the following messages appear on the CLI console to indicate that the unit joined the cluster and had its configuring synchronized with the

primary unit.

```
slave's configuration is not in sync with master's, sequence:0
slave's configuration is not in sync with master's, sequence:1
  slave's configuration is not in sync with master's, sequence:2
slave's configuration is not in sync with master's, sequence:3
  slave's configuration is not in sync with master's, sequence:4
  slave starts to sync with master
logout all admin users
slave succeeded to sync with master
```

Console messages when configuration synchronization fails

If you connect to the console of a subordinate unit that is out of synchronization with the primary unit, messages similar to the following are displayed.

```
slave is not in sync with master, sequence:0. (type 0x3)
slave is not in sync with master, sequence:1. (type 0x3)
slave is not in sync with master, sequence:2. (type 0x3)
slave is not in sync with master, sequence:3. (type 0x3)
slave is not in sync with master, sequence:4. (type 0x3)
global compared not matched
```

If synchronization problems occur the console message sequence may be repeated over and over again. The messages all include a type value (in the example `type 0x3`). The type value can help Fortinet Support diagnose the synchronization problem.

Comparing checksums of cluster units

You can use the `diagnose sys ha checksum show` command to compare the configuration checksums of all cluster units. The output of this command shows checksums labeled `global` and `all` as well as checksums for each of the VDOMs including the `root` VDOM. The `get system ha-nonsync-csum` command can be used to display similar information; however, this command is intended to be used by FortiManager.

The primary unit and subordinate unit checksums should be the same. If they are not you can use the `execute ha synchronize start` command to force a synchronization.

The following command output is for the primary unit of a cluster that does not have multiple VDOMs enabled:

```
diagnose sys ha checksum show
is_manage_master()=1, is_root_master()=1
debugzone
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5

checksum
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5
```

The following command output is for a subordinate unit of the same cluster:

```
diagnose sys ha checksum show
is_manage_master()=0, is_root_master()=0
debugzone
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5

checksum
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5
```

The following example shows using this command for the primary unit of a cluster with multiple VDOMs. Two VDOMs have been added named `test` and `Eng_vdm`.

From the primary unit:

```

config global
  diagnose sys ha checksum show
  is_manage_master()=1, is_root_master()=1
  debugzone
  global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
  test: a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
  root: 3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
  Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
  all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53

  checksum
  global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
  test: a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
  root: 3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
  Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
  all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53

```

From the subordinate unit:

```

config global
  diagnose sys ha checksum show
  is_manage_master()=0, is_root_master()=0
  debugzone
  global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
  test: a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
  root: 3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
  Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09

  all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53

```

How to diagnose HA out of sync messages

This section describes how to use the `diagnose sys ha checksum show` and `diagnose debug` commands to diagnose the cause of HA out of sync messages.

If HA synchronization is not successful, use the following procedures on each cluster unit to find the cause.

To determine why HA synchronization does not occur

1. Connect to each cluster unit CLI by connected to the console port.
2. Enter the following commands to enable debugging and display HA out of sync messages.

```

diagnose debug enable
diagnose debug console timestamp enable
diagnose debug application hataalk -1
diagnose debug application hasync -1

```

Collect the console output and compare the out of sync messages with the information in the table [HA out of sync object messages and the configuration objects that they reference on page 1540](#).

3. Enter the following commands to turn off debugging.

```

diagnose debug disable
diagnose debug reset

```

To determine what part of the configuration is causing the problem

If the previous procedure displays messages that include sync object 0x30 (for example, `HA_SYNC_SETTING_CONFIGURATION = 0x03`) there is a synchronization problem with the configuration. Use the following steps to determine the part of the configuration that is causing the problem.

If your cluster consists of two cluster units, use this procedure to capture the configuration checksums for each unit. If your cluster consists of more than two cluster units, repeat this procedure for all cluster units that returned messages that include 0x30 sync object messages.

1. Connect to each cluster unit CLI by connected to the console port.
2. Enter the following command to turn on terminal capture
`diagnose debug enable`
3. Enter the following command to stop HA synchronization.
`execute ha sync stop`
4. Enter the following command to display configuration checksums.
`diagnose sys ha checksum show global`
5. Copy the output to a text file.
6. Repeat for all affected units.
7. Compare the text file from the primary unit with the text file from each cluster unit to find the checksums that do not match.

You can use a diff function to compare text files.

8. Repeat for the root VDOM:
`diagnose sys ha checksum show root`
9. Repeat for all VDOMS (if multiple VDOM configuration is enabled):
`diagnose sys ha checksum show <vdom-name>`
10. You can also use the `grep` option to just display checksums for parts of the configuration.
For example to display system related configuration checksums in the root VDOM or log-related checksums in the global configuration:

```
diagnose sys ha checksum root | grep system
diagnose sys ha checksum global | grep log
```

Generally it is the first non-matching checksum that is the cause of the synchronization problem.

11. Attempt to remove/change the part of the configuration that is causing the problem. You can do this by making configuration changes from the primary unit or subordinate unit CLI.
12. Enter the following commands to start HA configuration and stop debugging:

```
execute ha sync start
diagnose debug disable
diagnose debug reset
```

Recalculating the checksums to resolve out of sync messages

Sometimes an error can occur when checksums are being calculated by the cluster. As a result of this calculation error the CLI console could display out of sync error messages even though the cluster is otherwise operating normally. You can also sometimes see checksum calculation errors in `diagnose sys ha checksum`

command output when the checksums listed in the `debugzone` output don't match the checksums in the `checksum` part of the output.

One solution to this problem could be to re-calculate the checksums. The re-calculated checksums should match and the out of sync error messages should stop appearing.

You can use the following command to re-calculate HA checksums:

```
diagnose sys ha checksum recalculate [<vdom-name> | global]
```

Just entering the command without options recalculates all checksums. You can specify a VDOM name to just recalculate the checksums for that VDOM. You can also enter `global` to recalculate the global checksum.

Determining what is causing a configuration synchronization problem

There are twenty-five FortiOS modules that have their configurations synchronized. It can be difficult to find the cause of a synchronization problem with so much data to analyze. You can use the following diagnose commands to more easily find modules that may be causing synchronization problems.

```
diagnose sys ha hasync-stats {all | most-recent [<seconds>] | by object [<number>]}
```

`all` displays the synchronization activity for all modules that happened since the hasync process started running (usually this would be since the cluster started-up).

`most-recent [<seconds>]` displays the most recently occurring synchronization events. You can include a time in seconds to display recent events that occurred during the time interval. If you don't include the number of seconds, the command displays the most recent events in the last 5 seconds. This option can be used to determine the module or modules that are currently synchronizing or attempting to synchronize. If no modules are currently synchronizing, the command just displays the most recent synchronization events.

`by-object [<number>]` displays the synchronization activity of a specific module, where `<number>` is the module number in the range 1 to 25. To display a list of all 25 modules and their numbers enter:

```
diagnose sys ha hasync-stats by-object ?
```

To display the most recent activity, enter:

```
diagnose sys ha hasync-stats most-recent 10
```

```
current-time/jiffies=2018-03-28 13:01:42/1148242:
```

```
hasync-obj=2(arp):
```

```
  epoll_handler=1(ev_arp_handler): start=1522256500.354400(2018-03-28 13:01:40),
end=1522256500.354406(2018-03-28 13:01:40), total=0.000006/1699
```

```
hasync-obj=5(config):
```

```
  timer=0(check_sync_status), add=1141764(2018-03-28 13:01:26), expire=1142764
(2018-03-28 13:01:36), end=1142764(2018-03-28 13:01:36), del=0(), total_call=1143
```

```
hasync-obj=8(time):
```

```
  obj_handler=0(packet): start=1522256497.851550(2018-03-28 13:01:37), end-
d=1522256497.851570(2018-03-28 13:01:37), total=0.000020/381
```

```
  timer=0(sync_timer), add=1140106(2018-03-28 13:01:10), expire=1143106(2018-03-
28 13:01:40), end=1143106(2018-03-28 13:01:40), del=0(), total_call=381
```

```
hasync-obj=21(hastats):
```

```
  obj_handler=0(packet): start=1522256499.760934(2018-03-28 13:01:39), end-
d=1522256499.760936(2018-03-28 13:01:39), total=0.000002/2285
```

```
  timer=0(hastats_timer), add=1142556(2018-03-28 13:01:34), expire=1143056(2018-
03-28 13:01:39), end=1143056(2018-03-28 13:01:39), del=0(), total_call=2286
```

The last few lines of this output shows activity with the `hastats` module, which is module 21. You can use the following command to see more information about synchronization activity with this module:

```
diagnose sys ha hasync-stats by-object 21
```

Synchronizing kernel routing tables

In a functioning cluster, the primary unit keeps all subordinate unit kernel routing tables (also called the forwarding information base FIB) up to date and synchronized with the primary unit. All synchronization activity takes place over the HA heartbeat link using TCP/703 and UDP/703 packets. After a failover, because of these routing table updates the new primary unit does not have to populate its kernel routing table before being able to route traffic. This gives the new primary unit time to rebuild its regular routing table after a failover.

Use the following command to view the regular routing table. This table contains all of the configured routes and routes acquired from dynamic routing protocols and so on. This routing table is not synchronized. On subordinate units this command will not produce the same output as on the primary unit.

```
get router info routing-table
```

Use the following command to view the kernel routing table (FIB). This is the list of resolved routes actually being used by the FortiOS kernel. The output of this command should be the same on the primary unit and the subordinate units.

```
get router info kernel
```

This section describes how clusters handle dynamic routing failover and also describes how to use CLI commands to control the timing of routing table updates of the subordinate unit routing tables from the primary unit.

Controlling how the FGCP synchronizes kernel routing table updates

You can use the following commands to control some of the timing settings that the FGCP uses when synchronizing routing updates from the primary unit to subordinate units and maintaining routes on the primary unit after a failover.

```
config system ha
  set route-hold <hold_integer>
  set route-ttl <ttl_integer>
  set route-wait <wait_integer>
end
```

Change how long routes stay in a cluster unit routing table

Change the `route-ttl` time to control how long routes remain in a cluster unit routing table. The time to live range is 5 to 3600 seconds. The default time to live is 10 seconds.

The time to live controls how long routes remain active in a cluster unit routing table after the cluster unit becomes a primary unit. To maintain communication sessions after a cluster unit becomes a primary unit, routes remain active in the routing table for the route time to live while the new primary unit acquires new routes.

By default, `route-ttl` is set to 10 which may mean that only a few routes will remain in the routing table after a failover. Normally keeping `route-ttl` to 10 or reducing the value to 5 is acceptable because acquiring new routes usually occurs very quickly, especially if graceful restart is enabled, so only a minor delay is caused by acquiring new routes.

If the primary unit needs to acquire a very large number of routes, or if for other reasons, there is a delay in acquiring all routes, the primary unit may not be able to maintain all communication sessions.

You can increase the route time to live if you find that communication sessions are lost after a failover so that the primary unit can use synchronized routes that are already in the routing table, instead of waiting to acquire new routes.

Change the time between routing updates

Change the `route-hold` time to change the time that the primary unit waits between sending routing table updates to subordinate units. The route hold range is 0 to 3600 seconds. The default route hold time is 10 seconds.

To avoid flooding routing table updates to subordinate units, set `route-hold` to a relatively long time to prevent subsequent updates from occurring too quickly. Flooding routing table updates can affect cluster performance if a great deal of routing information is synchronized between cluster units. Increasing the time between updates means that this data exchange will not have to happen so often.

The `route-hold` time should be coordinated with the `route-wait` time.

Change the time the primary unit waits after receiving a routing update

Change the `route-wait` time to change how long the primary unit waits after receiving routing updates before sending the updates to the subordinate units. For quick routing table updates to occur, set `route-wait` to a relatively short time so that the primary unit does not hold routing table changes for too long before updating the subordinate units.

The `route-wait` range is 0 to 3600 seconds. The default `route-wait` is 0 seconds.

Normally, because the `route-wait` time is 0 seconds the primary unit sends routing table updates to the subordinate units every time its routing table changes.

Once a routing table update is sent, the primary unit waits the `route-hold` time before sending the next update.

Usually routing table updates are periodic and sporadic. Subordinate units should receive these changes as soon as possible so `route-wait` is set to 0 seconds. `route-hold` can be set to a relatively long time because normally the next route update would not occur for a while.

In some cases, routing table updates can occur in bursts. A large burst of routing table updates can occur if a router or a link on a network fails or changes. When a burst of routing table updates occurs, there is a potential that the primary unit could flood the subordinate units with routing table updates. Flooding routing table updates can affect cluster performance if a great deal of routing information is synchronized between cluster units. Setting `route-wait` to a longer time reduces the frequency of additional updates and prevents flooding of routing table updates from occurring.

Configuring graceful restart for dynamic routing failover

When an HA failover occurs, neighbor routers will detect that the cluster has failed and remove it from the network until the routing topology stabilizes. During that time the routers may stop sending IP packets to the cluster and communication sessions that would normally be processed by the cluster may time out or be dropped. Also the new primary unit will not receive routing updates and so will not be able to build and maintain its routing database.

You can solve this problem by configuring graceful restart for the dynamic routing protocols that you are using. This section describes configuring graceful restart for OSPF and BGP.

To support graceful restart you should make sure the new primary unit keeps its synchronized routing data long enough to acquire new routing data. You should also increase the HA route time to live, route wait, and route hold values to 60 using the following CLI command:

```
config system ha
    set route-ttl 60
    set route-wait 60
    set route-hold 60
end
```

Graceful OSPF restart

You can configure graceful restart (also called nonstop forwarding (NSF) as described in [RFC3623](#) (Graceful OSPF Restart) to solve the problem of dynamic routing failover. If graceful restart is enabled on neighbor routers, they will keep sending packets to the cluster following the HA failover instead of removing it from the network. The neighboring routers assume that the cluster is experiencing a graceful restart.

After the failover, the new primary unit can continue to process communication sessions using the synchronized routing data received from the failed primary unit before the failover. This gives the new primary unit time to update its routing table after the failover.

You can use the following commands to enable graceful restart or NSF on Cisco routers:

```
router ospf 1
    log-adjacency-changes
    nsf ietf helper strict-lsa-checking
```

If the cluster is running OSPF, use the following command to enable graceful restart for OSPF:

```
config router ospf
    set restart-mode graceful-restart
end
```

Graceful BGP restart

If the cluster is running BGP only the primary unit keeps BGP peering connections. When a failover occurs, the BGP peering needs to be reestablished. This will happen if you enable BGP graceful restart which causes the adjacent routers to keep the routes active while the BGP peering is restarted by the new primary unit.

Enabling BGP graceful restart causes the FortiGate BGP process to restart which can temporarily disrupt traffic through the cluster. So normally you should wait for a quiet time or a maintenance period to enable BGP graceful restart.

Use the following command to enable graceful restart for BGP and set some graceful restart options.

```
config router bgp
    set graceful-restart enable
    set graceful-restart-time 120
    set graceful-stalepath-time 360
    set graceful-update-delay 120
end
```

Notifying BGP neighbors when graceful restart is enabled

You can add BGP neighbors and configure the cluster unit to notify these neighbors that it supports graceful restart.

```
config router bgp
```

```
config neighbor
  edit <neighbor_address_Ipv4>
    set capability-graceful-restart enable
  end
end
```

Bidirectional Forwarding Detection (BFD) enabled BGP graceful restart

You can add a BFD enabled BGP neighbor as a static BFD neighbor using the following command. This example shows how to add a BFD neighbor with IP address 172.20.121.23 that is on the network connected to port4:

```
config router bfd
  config neighbor
    edit 172.20.121.23
      set port4
    end
  end
end
```

The FGCP supports graceful restart of BFD enabled BGP neighbors. The `config router bfd` command is needed as the BGP auto-start timer is 5 seconds. After HA failover, BGP on the new primary unit has to wait for 5 seconds to connect to its neighbors, and then register BFD requests after establishing the connections. With static BFD neighbors, BFD requests and sessions can be created as soon as possible after the failover. The new command `get router info bfd requests` shows the BFD peer requests.

A BFD session created for a static BFD neighbor/peer request will initialize its state as "INIT" instead of "DOWN" and its detection time `asbfd-required-min-rx * bfd-detect-mult` milliseconds.

When a BFD control packet with nonzero `your_discr` is received, if no session can be found to match the `your_discr`, instead of discarding the packet, other fields in the packet, such as addressing information, are used to choose one session that was just initialized, with zero as its remote discriminator.

When a BFD session in the up state receives a control packet with zero as `your_discr` and down as the state, the session will change its state into down but will not notify this down event to BGP and/or other registered clients.

Link failover (port monitoring or interface monitoring)

Link failover means that if a monitored interface fails, the cluster reorganizes to reestablish a link to the network that the monitored interface was connected to and to continue operating with minimal or no disruption of network traffic.

You configure monitored interfaces (also called interface monitoring or port monitoring) by selecting the interfaces to monitor as part of the cluster HA configuration.

You can monitor up to 64 interfaces.

The interfaces that you can monitor appear on the port monitor list. You can monitor all FortiGate interfaces including redundant interfaces and 802.3ad aggregate interfaces.

You cannot monitor the following types of interfaces (you cannot select the interfaces on the port monitor list):

- FortiGate interfaces that contain an internal switch.
- VLAN subinterfaces.
- IPsec VPN interfaces.
- Individual physical interfaces that have been added to a redundant or 802.3ad aggregate interface.
- FortiGate-5000 series backplane interfaces that have not been configured as network interfaces.

If you are configuring a virtual cluster you can create a different port monitor configuration for each virtual cluster. Usually for each virtual cluster you would monitor the interfaces that have been added to the virtual domains in each virtual cluster.

Wait until after the cluster is up and running to enable interface monitoring. You do not need to configure interface monitoring to get a cluster up and running and interface monitoring will cause failovers if for some reason during initial setup a monitored interface has become disconnected. You can always enable interface monitoring once you have verified that the cluster is connected and operating properly.

You should only monitor interfaces that are connected to networks, because a failover may occur if you monitor an unconnected interface.

To enable interface monitoring - GUI

Use the following steps to monitor the port1 and port2 interfaces of a cluster.

1. Connect to the cluster GUI.
 2. Go to **System > HA** and edit the primary unit (**Role** is **MASTER**).
 3. Select the **Port Monitor** check boxes for the **port1** and **port2** interfaces and select **OK**.
- The configuration change is synchronized to all cluster units.

To enable interface monitoring - CLI

Use the following steps to monitor the port1 and port2 interfaces of a cluster.

1. Connect to the cluster CLI.
2. Enter the following command to enable interface monitoring for port1 and port2.

```
configure system ha
  set monitor port1 port2
end
```

The following example shows how to enable monitoring for the external, internal, and DMZ interfaces.

```
config system ha
  set monitor external internal dmz
end
```

With interface monitoring enabled, during cluster operation, the cluster monitors each cluster unit to determine if the monitored interfaces are operating and connected. Each cluster unit can detect a failure of its network interface hardware. Cluster units can also detect if its network interfaces are disconnected from the switch they should be connected to.

Cluster units cannot determine if the switch that its interfaces are connected to is still connected to the network. However, you can use remote IP monitoring to make sure that the cluster unit can connect to downstream network devices. See [Remote link failover on page 1556](#).

Because the primary unit receives all traffic processed by the cluster, a cluster can only process traffic from a network if the primary unit can connect to it. So, if the link between a network and the primary unit fails, to maintain communication with this network, the cluster must select a different primary unit; one that is still

connected to the network. Unless another link failure has occurred, the new primary unit will have an active link to the network and will be able to maintain communication with it.

To support link failover, each cluster unit stores link state information for all monitored cluster units in a link state database. All cluster units keep this link state database up to date by sharing link state information with the other cluster units. If one of the monitored interfaces on one of the cluster units becomes disconnected or fails, this information is immediately shared with all cluster units.

If a monitored interface on the primary unit fails

If a monitored interface on the primary unit fails, the cluster renegotiates to select a new primary unit using the process described in [Primary unit selection on page 1385](#). Because the cluster unit with the failed monitored interface has the lowest monitor priority, a different cluster unit becomes the primary unit. The new primary unit should have fewer link failures.

After the failover, the cluster resumes and maintains communication sessions in the same way as for a device failure. See [Device failover on page 1522](#).

If a monitored interface on a subordinate unit fails

If a monitored interface on a subordinate unit fails, this information is shared with all cluster units. The cluster does not renegotiate. The subordinate unit with the failed monitored interface continues to function in the cluster.

In an active-passive cluster after a subordinate unit link failover, the subordinate unit continues to function normally as a subordinate unit in the cluster.

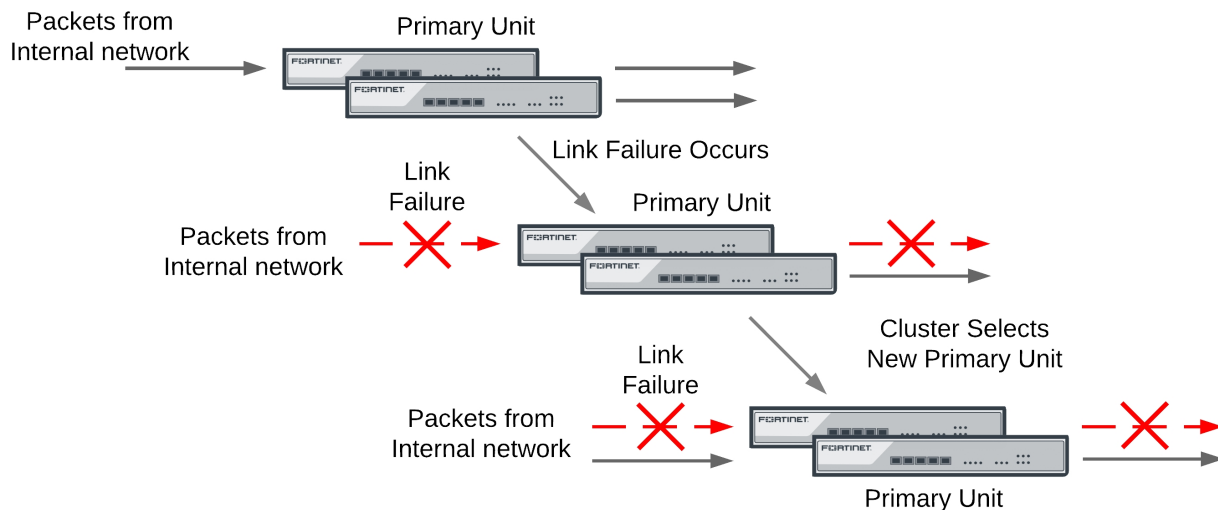

In an active-active cluster after a subordinate unit link failure:

- The subordinate unit with the failed monitored interface can continue processing connections between functioning interfaces. However, the primary unit stops sending sessions to a subordinate unit that use any failed monitored interfaces on the subordinate unit.
- If session pickup is enabled, all sessions being processed by the subordinate unit failed interface that can be failed over are failed over to other cluster units. Sessions that cannot be failed over are lost and have to be restarted.
- If session pickup is not enabled all sessions being processed by the subordinate unit failed interface are lost.

How link failover maintains traffic flow

Monitoring an interface means that the interface is connected to a high priority network. As a high priority network, the cluster should maintain traffic flow to and from the network, even if a link failure occurs. Because the primary unit receives all traffic processed by the cluster, a cluster can only process traffic from a network if the primary unit can connect to it. So, if the link that the primary unit has to a high priority network fails, to maintain traffic flow to and from this network, the cluster must select a different primary unit. This new primary unit should have an active link to the high priority network.

A link failure causes a cluster to select a new primary unit

If a monitored interface on the primary unit fails, the cluster renegotiates and selects the cluster unit with the highest monitor priority to become the new primary unit. The cluster unit with the highest monitor priority is the cluster unit with the most monitored interfaces connected to networks.

After a link failover, the primary unit processes all traffic and all subordinate units, even the cluster unit with the link failure, share session and link status. In addition all configuration changes, routes, and IPsec SAs are synchronized to the cluster unit with the link failure.

In an active-active cluster, the primary unit load balances traffic to all the units in the cluster. The cluster unit with the link failure can process connections between its functioning interfaces (for, example if the cluster has connections to an internal, external, and DMZ network, the cluster unit with the link failure can still process connections between the external and DMZ networks).

Recovery after a link failover and controlling primary unit selection (controlling falling back to the prior primary unit)

If you find and correct the problem that caused a link failure (for example, re-connect a disconnected network cable) the cluster updates its link state database and re-negotiates to select a primary unit.

What happens next depends on how the cluster configuration affects primary unit selection:

- The former primary unit will once again become the primary unit (falling back to becoming the primary unit)
- The primary unit will not change.

As described in [Primary unit selection and age on page 1387](#), when the link is restored, if no options are configured to control primary unit selection and the cluster age difference is less than 300 seconds the former

primary unit will once again become the primary unit. If the age differences are greater than 300 seconds then a new primary unit is not selected. Since you have no control on the age difference the outcome can be unpredictable. This is not a problem in cases where its not important which unit becomes the primary unit.

Preventing a primary unit change after a failed link is restored

Some organizations will not want the cluster to change primary units when the link is restored. Instead they would rather wait to restore the primary unit during a maintenance window. This functionality is not directly supported, but you can experiment with changing some primary unit selection settings. For example, in most cases it should work to enable override on all cluster units and make sure their priorities are the same. This should mean that the primary unit should not change after a failed link is restored.

Then, when you want to restore the original primary unit during a maintenance window you can just set its Device Priority higher. After it becomes the primary unit you can reset all device priorities to the same value. Alternatively during a maintenance window you could reboot the current primary unit and any subordinate units except the one that you want to become the primary unit.

If the `override` CLI keyword is enabled on one or more cluster units and the device priority of a cluster unit is set higher than the others, when the link failure is repaired and the cluster unit with the highest device priority will always become the primary unit.

Testing link failover

You can test link failure by disconnecting the network cable from a monitored interface of a cluster unit. If you disconnect a cable from a primary unit monitored interface the cluster should renegotiate and select one of the other cluster units as the primary unit. You can also verify that traffic received by the disconnected interface continues to be processed by the cluster after the failover.

If you disconnect a cable from a subordinate unit interface the cluster will not renegotiate.

Updating MAC forwarding tables when a link failover occurs

When a FortiGate HA cluster is operating and a monitored interface fails on the primary unit, the primary unit usually becomes a subordinate unit and another cluster unit becomes the primary unit. After a link failover, the new primary unit sends gratuitous ARP packets to refresh the MAC forwarding tables (also called arp tables) of the switches connected to the cluster. This is normal link failover operation.

Even when gratuitous ARP packets are sent, some switches may not be able to detect that the primary unit has become a subordinate unit and will keep sending packets to the former primary unit. This can occur if the switch does not detect the failure and does not clear its MAC forwarding table.

You have another option available to make sure the switch detects the failover and clears its MAC forwarding tables. You can use the following command to cause a cluster unit with a monitored interface link failure to briefly shut down all of its interfaces (except the heartbeat interfaces) after the failover occurs:

```
config system ha
    set link-failed-signal enable
end
```

Usually this means each interface of the former primary unit is shut down for about a second. When this happens the switch should be able to detect this failure and clear its MAC forwarding tables of the MAC addresses of the former primary unit and pickup the MAC addresses of the new primary unit. Each interface will shut down for a second but the entire process usually takes a few seconds. The more interfaces the FortiGate has, the longer it will take.

Normally, the new primary unit also sends gratuitous ARP packets that also help the switch update its MAC forwarding tables to connect to the new primary unit. If `link-failed-signal` is enabled, sending gratuitous ARP packets is optional and can be disabled if you don't need it or if its causing problems. See [Disabling gratuitous ARP packets after a failover on page 1532](#)

Multiple link failures

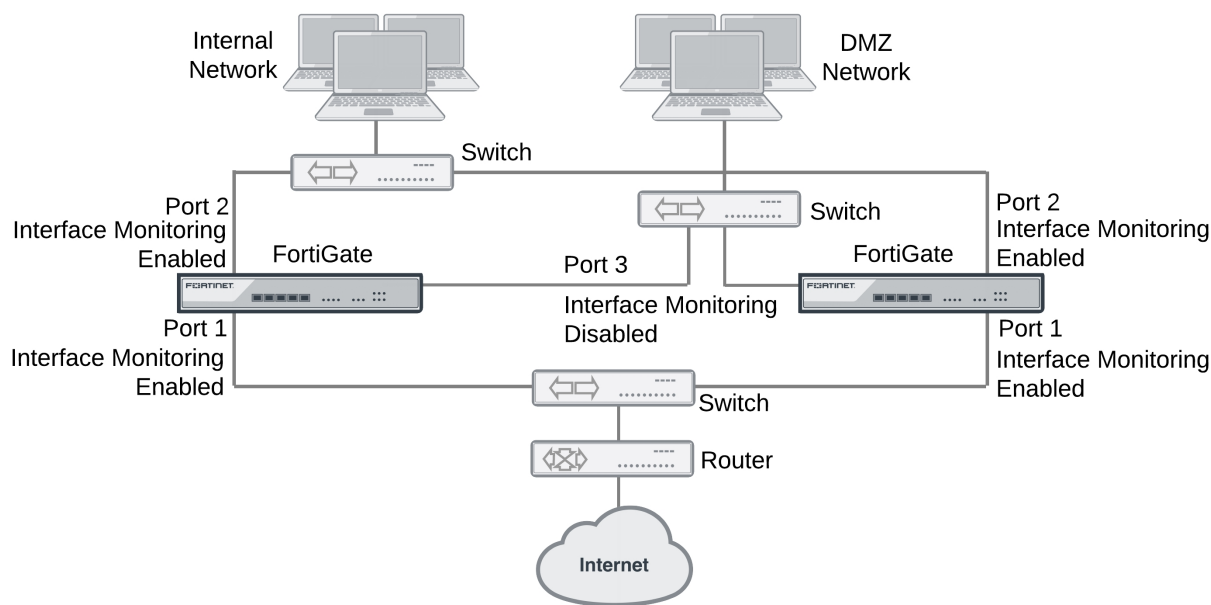

Every time a monitored interface fails, the cluster repeats the processes described above. If multiple monitored interfaces fail on more than one cluster unit, the cluster continues to negotiate to select a primary unit that can provide the most network connections.

Example link failover scenarios

For the following examples, assume a cluster configuration consisting of two FortiGates (FGT_1 and FGT_2) connected to three networks: internal using port2, external using port1, and DMZ using port3. In the HA configuration, the device priority of FGT_1 is set higher than the unit priority of FGT_2.

The cluster processes traffic flowing between the internal and external networks, between the internal and DMZ networks, and between the external and DMZ networks. If there are no link failures, FGT1 becomes the primary unit because it has the highest device priority.

Sample link failover scenario topology

Example the port1 link on FGT_1 fails

If the port1 link on FGT_1 fails, FGT_2 becomes primary unit because it has fewer interfaces with a link failure. If the cluster is operating in active-active mode, the cluster load balances traffic between the internal network

(port2) and the DMZ network (port3). Traffic between the internet (port1) and the internal network (port2) and between the internet (port1) and the DMZ network (port3) is processed by the primary unit only.

Example port2 on FGT_1 and port1 on FGT_2 fail

If port2 on FGT_1 and port1 on FGT_2 fail, then FGT_1 becomes the primary unit. After both of these link failures, both cluster units have the same monitor priority. So the cluster unit with the highest device priority (FGT_1) becomes the primary unit.

Only traffic between the internet (port1) and DMZ (port3) networks can pass through the cluster and the traffic is handled by the primary unit only. No load balancing will occur if the cluster is operating in active-active mode.

Monitoring VLAN interfaces

If the FortiGates in the cluster have VLAN interfaces, you can use the following command to monitor all VLAN interfaces and write a log message if one of the VLAN interfaces is found to be down.

Once configured, this feature works by verifying that the primary unit can connect to the subordinate unit over each VLAN. This verifies that the switch that the VLAN interfaces are connected to is configured correctly for each VLAN. If the primary unit cannot connect to the subordinate unit over one of the configured VLANs the primary unit writes a link monitor log message indicating that the named VLAN went down (log message id 20099).

Use the following CLI command to enable monitoring VLAN interfaces:

```
config system ha-monitor
  set monitor-vlan enable/disable
  set vlan-hb-interval <interval_seconds>
  set vlan-hb-lost-threshold <vlan-lost-heartbeat-threshold>
end
```

`vlan-hb-interval` is the time between sending VLAN heartbeat packets over the VLAN. The VLAN heartbeat range is 1 to 30 seconds. The default is 5 seconds.

`vlan-hb-lost-threshold` is the number of consecutive VLAN heartbeat packets that are not successfully received across the VLAN before assuming that the VLAN is down. The default value is 3, meaning that if 3 heartbeat packets sent over the VLAN are not received then the VLAN is considered to be down. The range is 1 to 60 packets.

A VLAN heartbeat interval of 5 means the time between heartbeat packets is five seconds. A VLAN heartbeat threshold of 3 means it takes $5 \times 3 = 15$ seconds to detect that a VLAN is down.

Sub-second failover

On FortiGate models 395xB and 3x40B HA link failover supports sub-second failover (that is a failover time of less than one second). Sub-second failover is available for interfaces that can issue a link failure system call when the interface goes down. When an interface experiences a link failure and sends the link failure system call, the FGCP receives the system call and initiates a link failover.

For interfaces that do not support subsection failover, port monitoring regularly polls the connection status of monitored interfaces. When a check finds that an interface has gone down, port monitoring causes a link failover. Sub-second failover results in a link failure being detected sooner because the system doesn't have to wait for the next poll to find out about the failure.

Sub-second failover can accelerate HA failover to reduce the link failover time to less than one second under ideal conditions. Actual failover performance may vary depending on traffic patterns and network configuration. For example, some network devices may respond slowly to an HA failover.

No configuration changes are required to support sub-second failover. However, for best sub-second failover results, the recommended heartbeat interval is 100ms and the recommended lost heartbeat threshold is 5 (see [Modifying heartbeat timing on page 1528](#)).

```
config system ha
    set hb-lost-threshold 5
    set hb-interval 1
end
```

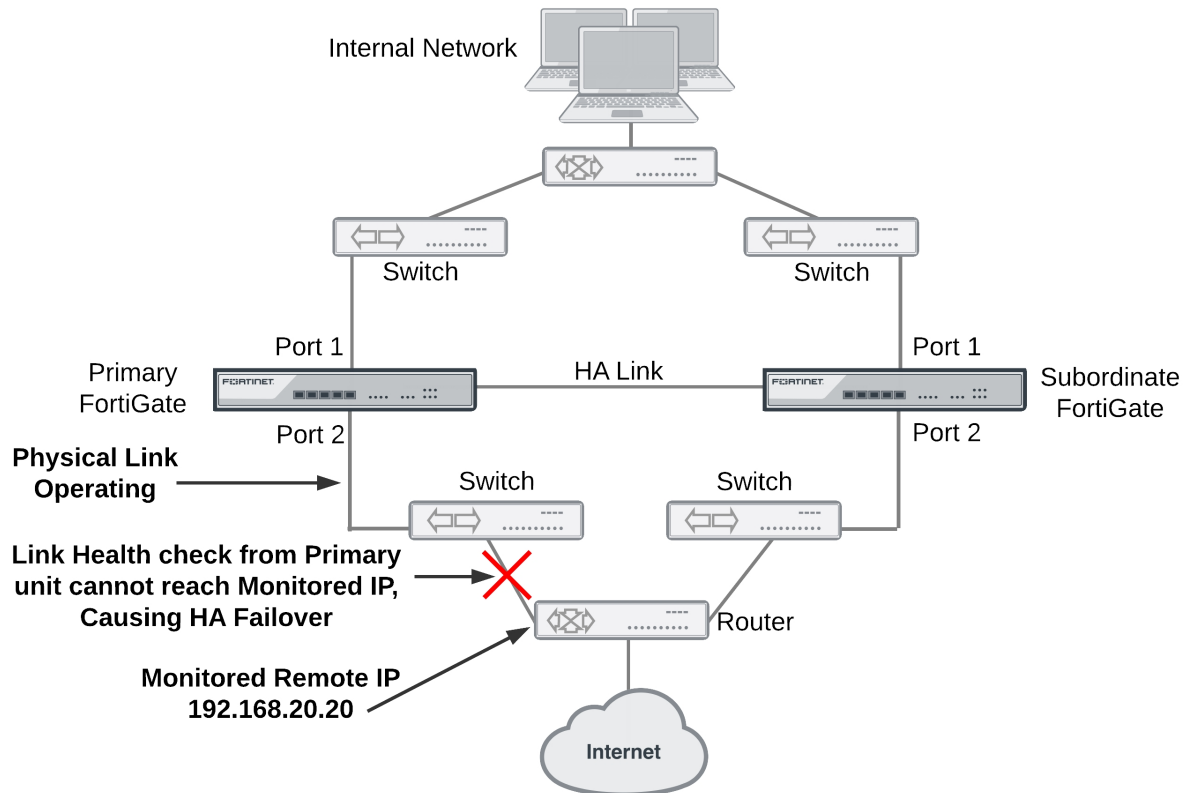

For information about how to reduce failover times, see [Failover performance on page 1566](#).

Remote link failover

Remote link failover (also called remote IP monitoring) is similar to HA port monitoring and link health monitoring (also known as dead gateway detection). Port monitoring causes a cluster to failover if a monitored primary unit interface fails or is disconnected. Remote IP monitoring uses link health monitors configured for FortiGate interfaces on the primary unit to test connectivity with IP addresses of network devices. Usually these would be IP addresses of network devices not directly connected to the cluster. For example, a downstream router. Remote IP monitoring causes a failover if one or more of these remote IP addresses does not respond to link health checking.

By being able to detect failures in network equipment not directly connected to the cluster, remote IP monitoring can be useful in a number of ways depending on your network configuration. For example, in a full mesh HA configuration, with remote IP monitoring, the cluster can detect failures in network equipment that is not directly connected to the cluster but that would interrupt traffic processed by the cluster if the equipment failed.

Example HA remote IP monitoring topology

In the simplified example topology shown above, the switch connected directly to the primary unit is operating normally but the link on the other side of the switches fails. As a result traffic can no longer flow between the primary unit and the internet.

To detect this failure you can create a link health monitor for port2 that causes the primary unit to test connectivity to 192.168.20.20. If the health monitor cannot connect to 192.268.20.20 the cluster fails over and the subordinate unit becomes the new primary unit. After the failover, the health check monitor on the new primary unit can connect to 192.168.20.20 so the failover maintains connectivity between the internal network and the internet through the cluster.

To configure remote IP monitoring

1. Enter the following commands to configure HA remote monitoring for the example topology.
 - Enter the `pingserver-monitor-interface` keyword to enable HA remote IP monitoring on port2.
 - Leave the `pingserver-failover-threshold` set to the default value of 5. This means a failover occurs if the link health monitor doesn't get a response after 5 attempts.
 - Enter the `pingserver-flip-timeout` keyword to set the flip timeout to 120 minutes. After a failover, if HA remote IP monitoring on the new primary unit also causes a failover, the flip timeout prevents the failover from occurring until the timer runs out. Setting the `pingserver-flip-timeout` to 120 means that remote IP monitoring can only cause a failover every 120 minutes. This flip timeout is required to prevent repeating failovers if remote IP monitoring causes a failover from all cluster units because none of the cluster units can connect to the monitored IP addresses.

```
config system ha
```

```

set pingserver-monitor-interface port2
set pingserver-failover-threshold 5
set pingserver-flip-timeout 120
end

```

2. Enter the following commands to add a link health monitor for the port2 interface and to set HA remote IP monitoring priority for this link health monitor.
 - Enter the `detectserver` keyword to set the health monitor server IP address to 192.168.20.20.
 - Leave the `ha-priority` keyword set to the default value of 1. You only need to change this priority if you change the HA `pingserver-failover-threshold`. The `ha-priority` setting is not synchronized among cluster units.

The `ha-priority` setting is not synchronized among cluster units. So if you want to change the `ha-priority` setting you must change it separately on each cluster unit. Otherwise it will remain set to the default value of 1.

- Use the `interval` keyword to set the time between link health checks and use the `failtime` keyword to set the number of times that a health check can fail before a failure is detected (the failover threshold). The following example reduces the failover threshold to 2 but keeps the health check interval at the default value of 5.

```

config system link-monitor
edit ha-link-monitor
set server 192.168.20.20
set srcintf port2
set ha-priority 1
set interval 5
set failtime 2
end

```

Configuring IPv6 remote IP monitoring

You can add link monitors to monitor remote IPv6 addresses. For example, use the following command:

```

config system link-monitor
edit port3
set addr-mode ipv6
set server 2001:db8:0:1
set protocol ping6
set ha-priority 1
set interval 5
set failtime 2
set gateway-ip6 2001:db8:0:2
set source-ip6 2001:db8:0:32
end

```

Adding HA remote IP monitoring to multiple interfaces

You can enable HA remote IP monitoring on multiple interfaces by adding more interface names to the `pingserver-monitor-interface` keyword. If your FortiGate configuration includes VLAN interfaces, aggregate interfaces and other interface types, you can add the names of these interfaces to the `pingserver-monitor-interface` keyword to configure HA remote IP monitoring for these interfaces.

For example, enable remote IP monitoring for interfaces named port2, port20, and vlan_234:

```

config system ha
    set pingserver-monitor-interface port2 port20 vlan_234
    set pingserver-failover-threshold 10
    set pingserver-flip-timeout 120
end

```

Then configure health monitors for each of these interfaces. In the following example, default values are accepted for all settings other than the server IP address.

```

config system link-monitor
    edit port2
        set server 192.168.20.20
    next
    edit port20
        set server 192.168.20.30
    next
    edit vlan_234
        set server 172.20.12.10
    end

```

Changing the link monitor failover threshold

If you have multiple link monitors you may want a failover to occur only if more than one of them fails.

For example, you may have 3 link monitors configured on three interfaces but only want a failover to occur if two of the link monitors fail. To do this you must set the HA priorities of the link monitors and the HA `pingserver-failover-threshold` so that the priority of one link monitor is less than the failover threshold but the added priorities of two link monitors is equal to or greater than the failover threshold. Failover occurs when the HA priority of all failed link monitors reaches or exceeds the threshold.

For example, set the failover threshold to 10 and monitor three interfaces:

```

config system ha
    set pingserver-monitor-interface port2 port20 vlan_234
    set pingserver-failover-threshold 10
    set pingserver-flip-timeout 120
end

```

Then set the HA priority of link monitor server to 5.

The HA Priority (`ha-priority`) setting is not synchronized among cluster units. In the following example, you must set the HA priority to 5 by logging into each cluster unit.

```

config system link-monitor
    edit port2
        set srcintf port2
        set server 192.168.20.20
        set ha-priority 5
    next
    edit port20
        set srcintf port20
        set server 192.168.20.30
        set ha-priority 5
    next
    edit vlan_234
        set srcintf vlan_234
        set server 172.20.12.10
    end

```

```
    set ha-priority 5
end
```

If only one of the link monitors fails, the total link monitor HA priority will be 5, which is lower than the failover threshold so a failover will not occur. If a second link monitor fails, the total link monitor HA priority of 10 will equal the failover threshold, causing a failover.

By adding multiple link monitors and setting the HA priorities for each, you can fine tune remote IP monitoring. For example, if it is more important to maintain connections to some networks you can set the HA priorities higher for these link monitors. And if it is less important to maintain connections to other networks you can set the HA priorities lower for these link monitors. You can also adjust the failover threshold so that if the cluster cannot connect to one or two high priority IP addresses a failover occurs. But a failover will not occur if the cluster cannot connect to one or two low priority IP addresses.

Monitoring multiple IP addresses from one interface

You can add multiple IP addresses to a single link monitor to use HA remote IP monitoring to monitor more than one IP address from a single interface. If you add multiple IP addresses, the health checking will be with all of the addresses at the same time. The link monitor only fails when no responses are received from all of the addresses.

```
config system link-monitor
    edit port2
        set srcintf port2
        set server 192.168.20.20 192.168.20.30 172.20.12.10
    end
```

Flip timeout

The HA remote IP monitoring configuration also involves setting a flip timeout. The flip timeout is required to reduce the frequency of failovers if, after a failover, HA remote IP monitoring on the new primary unit also causes a failover. This can happen if the new primary unit cannot connect to one or more of the monitored remote IP addresses. The result could be that until you fix the network problem that blocks connections to the remote IP addresses, the cluster will experience repeated failovers. You can control how often the failovers occur by setting the flip timeout. The flip timeout stops HA remote IP monitoring from causing a failover until the primary unit has been operating for the duration of the flip timeout.

If you set the flip timeout to a relatively high number of minutes you can find and repair the network problem that prevented the cluster from connecting to the remote IP address without the cluster experiencing very many failovers. Even if it takes a while to detect the problem, repeated failovers at relatively long time intervals do not usually disrupt network traffic.

Use the following command to set the flip timeout to 3 hours (360 minutes):

```
config system ha
    set pingserver-flip-timeout 360
end
```

Restoring normal cluster operation after the remote link is restored

In a remote IP monitoring configuration, if you also want the same cluster unit to always be the primary unit you can set its device priority higher and enable override. With this configuration, when a remote IP monitoring failover occurs, after the flip timeout expires another failover will occur (because override is enabled) and the unit with override enabled becomes the primary unit again. So the cluster automatically returns to normal operation.

The primary unit starts remote IP monitoring again. If the remote link is restored the cluster continues to operate normally. If, however, the remote link is still down, remote link failover causes the cluster to failover again. This will repeat each time the flip timeout expires until the failed remote link is restored.

You can use the `pingserver-slave-force-reset` option to control this behavior. By default this option is enabled and the behavior described above occurs. The overall behavior is that when the remote link is restored the cluster automatically returns to normal operation after the flip timeout.

If you disable `pingserver-slave-force-reset` after the initial remote IP monitoring failover nothing will happen after the flip timeout (as long as the new primary unit doesn't experience some kind of failover). The result is that repeated failovers no longer happen. But it also means that the original primary unit will remain the subordinate unit and will not resume operating as the primary unit.

Detecting HA remote IP monitoring failovers

Just as with any HA failover, you can detect HA remote IP monitoring failovers by using SNMP to monitor for HA traps. You can also use alert email to receive notifications of HA status changes and monitor log messages for HA failover log messages. In addition, FortiGates send the critical log message `Ping Server is down` when a ping server fails. The log message includes the name of the interface that the ping server has been added to.

Failover and attached network equipment

It normally takes a cluster approximately 6 seconds to complete a failover. However, the actual failover time experienced by your network users may depend on how quickly the switches connected to the cluster interfaces accept the cluster MAC address update from the primary unit. If the switches do not recognize and accept the gratuitous ARP packets and update their MAC forwarding table, the failover time will increase.

Also, individual session failover depends on whether the cluster is operating in active-active or active-passive mode, and whether the content of the traffic is to be virus scanned. Depending on application behavior, it may take a TCP session a longer period of time (up to 30 seconds) to recover completely.

Monitoring cluster units for failover

You can use logging and SNMP to monitor cluster units for failover. Both the primary and subordinate units can be configured to write log messages and send SNMP traps if a failover occurs. You can also log into the cluster GUI and CLI to determine if a failover has occurred.

NAT/Route mode active-passive cluster packet flow

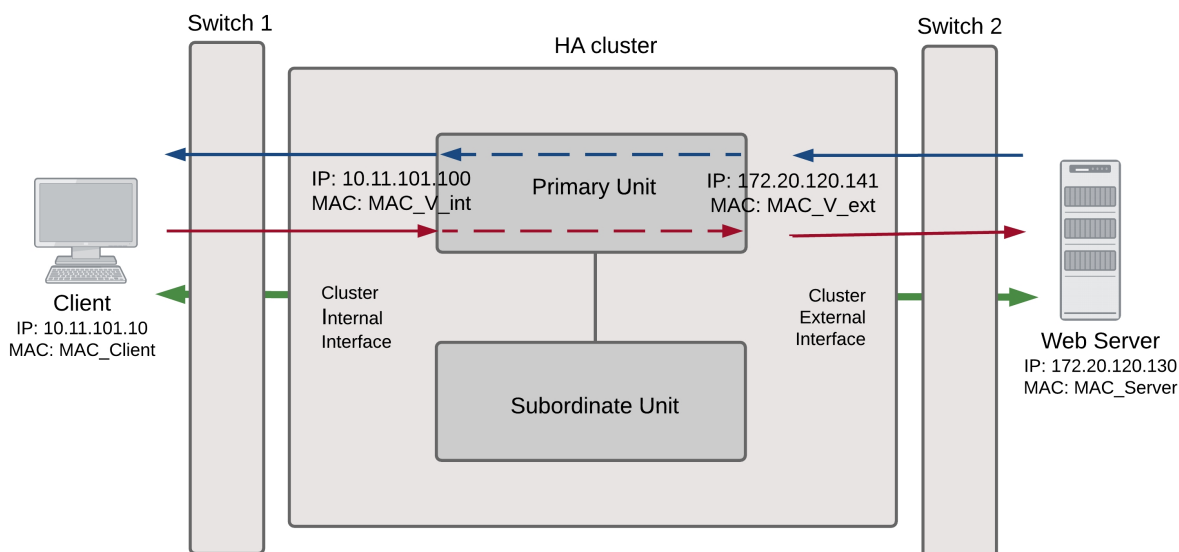

This section describes how packets are processed and how failover occurs in an active-passive HA cluster running in NAT/Route mode. In the example, the NAT/Route mode cluster acts as the internet firewall for a client computer's internal network. The client computer's default route points at the IP address of the cluster internal interface. The client connects to a web server on the internet. internet routing routes packets from the cluster external interface to the web server, and from the web server to the cluster external interface.

In an active-passive cluster operating in NAT/Route mode, four MAC addresses are involved in communication between the client and the web server when the primary unit processes the connection:

- Internal virtual MAC address (MAC_V_int) assigned to the primary unit internal interface,
- External virtual MAC address (MAC_V_ext) assigned to the primary unit external interface,
- Client MAC address (MAC_Client),
- Server MAC address (MAC_Server),

In NAT/Route mode, the HA cluster works as a gateway when it responds to ARP requests. Therefore, the client and server only know the gateway MAC addresses. The client only knows the cluster internal virtual MAC address (MAC_V_int) and the server only know the cluster external virtual MAC address (MAC_V_ext).

NAT/Route mode active-passive packet flow

Packet flow from client to web server

1. The client computer requests a connection from 10.11.101.10 to 172.20.120.130.
2. The default route on the client computer recognizes 10.11.101.100 (the cluster IP address) as the gateway to the external network where the web server is located.
3. The client computer issues an ARP request to 10.11.101.100.
4. The primary unit intercepts the ARP request, and responds with the internal virtual MAC address (MAC_V_int) which corresponds to its IP address of 10.11.101.100.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	172.20.120.130	MAC_V_int

6. The primary unit processes the packet.
7. The primary unit forwards the packet from its external interface to the web server.

	IP address	MAC address
Source	172.20.120.141	MAC_V_ext
Destination	172.20.120.130	MAC_Server

8. The primary unit continues to process packets in this way unless a failover occurs.

Packet flow from web server to client

1. When the web server responds to the client's packet, the cluster external interface IP address (172.20.120.141) is recognized as the gateway to the internal network.
2. The web server issues an ARP request to 172.20.120.141.
3. The primary unit intercepts the ARP request, and responds with the external virtual MAC address (MAC_V_ext) which corresponds its IP address of 172.20.120.141.
4. The web server then sends response packets to the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_Server
Destination	172.20.120.141	MAC_V_ext

5. The primary unit processes the packet.
6. The primary unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	172.20.120.130	MAC_V_int
Destination	10.11.101.10	MAC_Client

7. The primary unit continues to process packets in this way unless a failover occurs.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails the subordinate unit becomes the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC addresses.
The new primary unit has the same IP addresses and MAC addresses as the failed primary unit.
3. The new primary unit sends gratuitous ARP packets from the internal interface to the 10.11.101.0 network to associate its internal IP address with the internal virtual MAC address.
4. The new primary unit sends gratuitous ARP packets to the 172.20.120.0 to associate its external IP address with the external virtual MAC address.
5. Traffic sent to the cluster is now received and processed by the new primary unit.
If there were more than two cluster units in the original cluster, these remaining units would become subordinate units.

Transparent mode active-passive cluster packet flow

This section describes how packets are processed and how failover occurs in an active-passive HA cluster running in transparent mode. The cluster is installed on an internal network in front of a mail server and the client connects to the mail server through the transparent mode cluster.

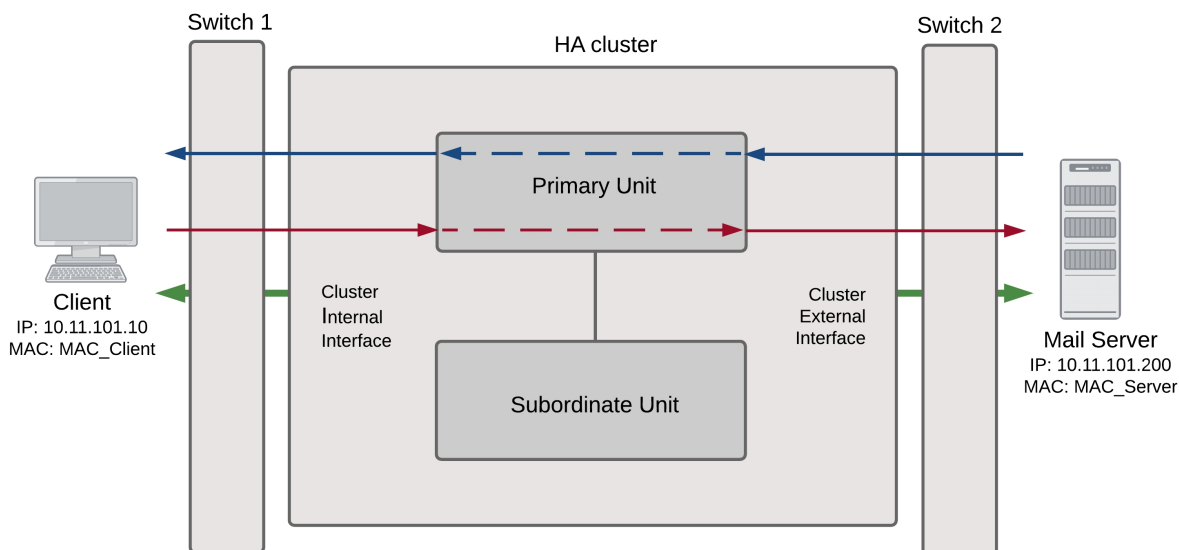

In an active-passive cluster operating in transparent mode, two MAC addresses are involved in the communication between a client and a server when the primary unit processes a connection:

- Client MAC address (MAC_Client)
- Server MAC address (MAC_Server)

The HA virtual MAC addresses are not directly involved in communication between the client and the server. The client computer sends packets to the mail server and the mail server sends responses. In both cases the packets are intercepted and processed by the cluster.

The cluster's presence on the network is transparent to the client and server computers. The primary unit sends gratuitous ARP packets to Switch 1 that associate all MAC addresses on the network segment connected to the cluster external interface with the HA virtual MAC address. The primary unit also sends gratuitous ARP packets to Switch 2 that associate all MAC addresses on the network segment connected to the cluster internal interface with the HA virtual MAC address. In both cases, this results in the switches sending packets to the primary unit interfaces.

Transparent mode active-passive packet flow

Packet flow from client to mail server

1. The client computer requests a connection from 10.11.101.10 to 10.11.101.200.
2. The client computer issues an ARP request to 10.11.101.200.
3. The primary unit forwards the ARP request to the mail server.
4. The mail server responds with its MAC address (MAC_Server) which corresponds to its IP address of 10.11.101.200. The primary unit returns the ARP response to the client computer.
5. The client's request packet reaches the primary unit internal interface.

IP address	MAC address
------------	-------------

Source	10.11.101.10	MAC_Client
Destination	10.11.101.200	MAC_Server

- The primary unit processes the packet.
- The primary unit forwards the packet from its external interface to the mail server.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	10.11.101.200	MAC_Server

- The primary unit continues to process packets in this way unless a failover occurs.

Packet flow from mail server to client

- To respond to the client computer, the mail server issues an ARP request to 10.11.101.10.
- The primary unit forwards the ARP request to the client computer.
- The client computer responds with its MAC address (MAC_Client) which corresponds to its IP address of 10.11.101.10. The primary unit returns the ARP response to the mail server.
- The mail server's response packet reaches the primary unit external interface.

	IP address	MAC address
Source	10.11.101.200	MAC_Server
Destination	10.11.101.10	MAC_Client

- The primary unit processes the packet.
- The primary unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	10.11.101.200	MAC_Server
Destination	10.11.101.10	MAC_Client

- The primary unit continues to process packets in this way unless a failover occurs.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

- If the primary unit fails, the subordinate unit negotiates to become the primary unit.
- The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC address.
- The new primary unit sends gratuitous ARP packets to switch 1 to associate its MAC address with the MAC addresses on the network segment connected to the external interface.
- The new primary unit sends gratuitous ARP packets to switch 2 to associate its MAC address with the MAC addresses on the network segment connected to the internal interface.
- Traffic sent to the cluster is now received and processed by the new primary unit.

If there were more than two cluster units in the original cluster, these remaining units would become subordinate units.

Failover performance

This section describes the designed device and link failover times for a FortiGate cluster and also shows results of a failover performance test.

Device failover performance

By design FGCP device failover time is 2 seconds for a two-member cluster with ideal network and traffic conditions. If sub-second failover is enabled the failover time can drop below 1 second.

All cluster units regularly receive HA heartbeat packets from all other cluster units over the HA heartbeat link. If any cluster unit does not receive a heartbeat packet from any other cluster unit for 2 seconds, the cluster unit that has not sent heartbeat packets is considered to have failed.

It may take another few seconds for the cluster to negotiate and re-distribute communication sessions. Typically if sub-second failover is not enabled you can expect a failover time of 9 to 15 seconds depending on the cluster and network configuration. The failover time can also be increased by more complex configurations and or configurations with network equipment that is slow to respond.

You can change the `hb-lost-threshold` to increase or decrease the device failover time. See [Modifying heartbeat timing on page 1528](#) for information about using `hb-lost-threshold`, and other heartbeat timing settings.

Link failover performance

Link failover time is controlled by how long it takes for a cluster to synchronize the cluster link database. When a link failure occurs, the cluster unit that experienced the link failure uses HA heartbeat packets to broadcast the updated link database to all cluster units. When all cluster units have received the updated database the failover is complete.

It may take another few seconds for the cluster to negotiate and re-distribute communication sessions.

Reducing failover times

- Keep the network configuration as simple as possible with as few as possible network connections to the cluster.
- If possible operate the cluster in transparent mode.
- Use high-performance switches to that the switches failover to interfaces connected to the new primary unit as quickly as possible.
- Use accelerated FortiGate interfaces. In some cases accelerated interfaces will reduce failover times.
- Make sure the FortiGate sends multiple gratuitous arp packets after a failover. In some cases, sending more gratuitous arp packets will cause connected network equipment to recognize the failover sooner. To send 10 gratuitous arp packets:

```
config system ha
  set arps 10
end
```

- Reduce the time between gratuitous arp packets. This may also caused connected network equipment to recognize the failover sooner. To send 50 gratuitous arp packets with 1 second between each packet:

```
config system ha
  set arps 50
```

```
    set arps-interval 1
end
```

- Reduce the number of lost heartbeat packets and reduce the heartbeat interval timers to be able to more quickly detect a device failure. To set the lost heartbeat threshold to 3 packets and the heartbeat interval to 100 milliseconds:

```
config system ha
    set hb-interval 1
    set hb-lost-threshold 3
end
```

- Reduce the hello state hold down time to reduce the amount of the time the cluster waits before transitioning from the hello to the work state. To set the hello state hold down time to 5 seconds:

```
config system ha
    set hello-holddown 5
end
```

- Enable sending a link failed signal after a link failover to make sure that attached network equipment responds as quickly as possible to a link failure. To enable the link failed signal:

```
config system ha
    set link-failed-signal enable
end
```

Session failover (session-pickup)

Session failover means that after the primary unit fails, communications sessions resume on the new primary unit with minimal or no interruption. Two categories of sessions need to be resumed after a failover:

- Sessions passing through the cluster
- Sessions terminated by the cluster

If you enable session failover (also called session-pickup) for the cluster, during cluster operation the primary unit informs the subordinate units of changes to the primary unit connection and state tables for sessions passing through the cluster, keeping the subordinate units up-to-date with the traffic currently being processed by the cluster. All synchronization activity takes place over the HA heartbeat link using TCP/703 and UDP/703 packets.

After a failover the new primary unit recognizes open sessions that were being handled by the cluster. The sessions continue to be processed by the new primary unit and are handled according to their last known state.

Session-pickup has some limitations. For example, session failover is not supported for sessions being scanned by proxy-based security profiles. Session failover is supported for sessions being scanned by flow-based security profiles; however, flow-based sessions that fail over are not inspected after they fail over. For more limitations, see [Session failover limitations for sessions passing through the cluster on page 1570](#).

Sessions terminated by the cluster include management sessions (such as HTTPS connections to the FortiGate GUI or SSH connection to the CLI as well as SNMP and logging and so on). Also included in this category are IPsec VPN, SSL VPN, sessions terminated by the cluster, explicit proxy, WAN Optimization and web caching. In general, whether or not session-pickup is enabled, these sessions do not failover and have to be restarted. There are some exceptions though, particularly for IPsec and SSL VPN. For more information, see [Session failover limitations for sessions terminated by the cluster on page 1573](#).

Enabling session-pickup for TCP, UDP, ICMP, and multicast session failover

To enable session-pickup, go to **System > HA** and enable session-pickup.

From the CLI enter:

```
config system ha
    set session-pickup enable
end
```

When session-pickup is enabled, the FGCP synchronizes the primary unit's TCP session table to all cluster units. As soon as a new TCP session is added to the primary unit session table, that session is synchronized to all cluster units. This synchronization happens as quickly as possible to keep the session tables synchronized.

If the primary unit fails, the new primary unit uses its synchronized session table to resume all TCP sessions that were being processed by the former primary unit with only minimal interruption. Under ideal conditions all TCP sessions should be resumed. This is not guaranteed though and under less than ideal conditions some TCP sessions may need to be restarted.

Enabling UDP and ICMP session failover

If session pickup is enabled, you can use the following command to also enable UDP and ICMP session failover:

```
config system ha
  set session-pickup-connectionless enable
end
```

Enabling multicast session failover

To configure multicast session failover, use the following command to change the multicast TTL timer to a smaller value than the default. The recommended setting to support multicast session failover is 120 seconds (2 minutes). The default setting is 600 seconds (10 minutes).

```
config system ha
  set multicast-ttl 120
end
```

The multicast TTL timer controls how long to keep synchronized multicast routes on the backup unit (so they are present on the backup unit when it becomes the new primary unit after a failover). If you set the multicast TTL lower the multicast routes on the backup unit are refreshed more often so are more likely to be accurate. Reducing this time causes route synchronization to happen more often and could affect performance.

If session pickup is disabled

If you leave session pickup disabled, the cluster does not keep track of sessions and after a failover, active sessions have to be restarted or resumed. Most session can be resumed as a normal result of how TCP/IP communications resumes communication after any routine network interruption.

The session-pickup setting does not affect session failover for sessions terminated by the cluster.

If you do not require session failover protection, leaving session pickup disabled may reduce CPU usage and reduce HA heartbeat network bandwidth usage. Also if your cluster is mainly being used for traffic that is not synchronized (for example, for proxy-based security profile processing) enabling session pickup is not recommended since most sessions will not be failed over anyway.

If session pickup is not enabled, the FGCP does not synchronize the primary unit session table to other cluster units and sessions do not resume after a failover. After a device or link failover all sessions are briefly interrupted and must be re-established at the application level after the cluster renegotiates.

Many protocols can successfully restart sessions with little, if any, loss of data. For example, after a failover, users browsing the web can just refresh their browsers to resume browsing. Since most HTTP sessions are very short, in most cases they will not even notice an interruption unless they are downloading large files. Users downloading a large file may have to restart their download after a failover.

Other protocols may experience data loss and some protocols may require sessions to be manually restarted. For example, a user downloading files with FTP may have to either restart downloads or restart their FTP client.

Improving session synchronization performance

Two HA configuration options are available to reduce the performance impact of enabling session-pickup. They include reducing the number of sessions that are synchronized by adding a session pickup delay and using more FortiGate interfaces for session synchronization.

Reducing the number of sessions that are synchronized

If session pickup is enabled, as soon as new sessions are added to the primary unit session table they are synchronized to the other cluster units. Enable the `session-pickup-delay` CLI option to reduce the number of sessions that are synchronized by synchronizing sessions only if they remain active for more than 30 seconds. Enabling this option could greatly reduce the number of sessions that are synchronized if a cluster typically processes very many short duration sessions, which is typical of most HTTP traffic for example.

Use the following command to enable a 30 second session pickup delay:

```
config system ha
    set session-pickup-delay enable
end
```

Enabling session pickup delay means that if a failover occurs more sessions may not be resumed after a failover. In most cases short duration sessions can be restarted with only a minor traffic interruption. However, if you notice too many sessions not resuming after a failover you might want to disable this setting.

Using multiple FortiGate interfaces for session synchronization

Using the `session-sync-dev` option you can select one or more FortiGate interfaces to use for synchronizing sessions as required for session pickup. Normally session synchronization occurs over the HA heartbeat link. Using this HA option means only the selected interfaces are used for session synchronization and not the HA heartbeat link. If you select more than one interface, session synchronization traffic is load balanced among the selected interfaces.

Moving session synchronization from the HA heartbeat interface reduces the bandwidth required for HA heartbeat traffic and may improve the efficiency and performance of the cluster, especially if the cluster is synchronizing a large number of sessions. Load balancing session synchronization among multiple interfaces can further improve performance and efficiency if the cluster is synchronizing a large number of sessions.

Use the following command to perform cluster session synchronization using the port10 and port12 interfaces.

```
config system ha
    set session-sync-dev port10 port12
end
```

Session synchronization packets use Ethertype 0x8892. The interfaces to use for session synchronization must be connected together either directly using the appropriate cable (possible if there are only two units in the cluster) or using switches. If one of the interfaces becomes disconnected the cluster uses the remaining interfaces for session synchronization. If all of the session synchronization interfaces become disconnected, session synchronization reverts back to using the HA heartbeat link. All session synchronization traffic is between the primary unit and each subordinate unit.

Since large amounts of session synchronization traffic can increase network congestion, it is recommended that you keep this traffic off of your network by using dedicated connections for it.

Session failover limitations for sessions passing through the cluster

This section contains information about session failover for communication sessions passing through the cluster. In general, if session pickup is enabled, session failover is supported for most TCP traffic. This section describes details about how this all works.

Protocol	Session Failover?
Most TCP sessions.	Supported if session-pickup is enabled. (More about TCP session failover on page 1571)
Multicast sessions	Supported if multicast session-pickup is enabled. (Enabling multicast session failover).
IPv6, NAT64, and NAT66	Supported if session-pickup is enabled.
Proxy-based security profile sessions	Not Supported, sessions have to be restarted. Proxy-based features require the FortiGate to maintain very large amounts of internal state information for each session. The FGCP does not synchronize this internal state information. As a result, proxy-based sessions are not failed over. Active-active clusters can resume some of these sessions after a failover. (Active-active HA subordinate units sessions can resume after a failover on page 1573)
Flow-based security profile sessions.	Supported if session-pickup is enabled. Flow-based sessions failover, but internal state information is not synchronized so sessions that fail over are no longer inspected by security profile functions. If both flow-based and proxy-based security profile features are applied to a TCP session, that session will not resume after a failover.
UDP and ICMP, or broadcast sessions	Supported if connectionless session-pickup is enabled. Otherwise, sessions have to be restarted. (UDP, ICMP, and broadcast packet session failover on page 1572)
GPRS Tunneling Protocol (GTP)	Supported with limitations. (FortiOS Carrier GTP session failover on page 1573)
SIP	Supported for active-passive HA only. (SIP session failover on page 1572)
SIMPLE, or SCCP signal session	Not supported, sessions have to be restarted.
SSL offloading and HTTP multiplexing	Not supported, sessions have to be restarted. (SSL offloading and HTTP multiplexing session failover on page 1573)

More about TCP session failover

TCP sessions that are not being processed by security profile features resume after a failover even if these sessions are accepted by security policies with security profiles. Only TCP sessions that are actually being processed by these security profile features do not resume after a failover. For example:

- TCP sessions that are not virus scanned, web filtered, spam filtered, content archived, or are not SIP, SIMPLE, or SCCP signal traffic resume after a failover, even if they are accepted by a security policy with security profile options enabled. For example, SNMP TCP sessions through the FortiGate resume after a failover because FortiOS does not apply any security profile options to SNMP sessions.
- TCP sessions for a protocol for which security profile features have not been enabled resume after a failover even if they are accepted by a security policy with security profile features enabled. For example, if you have not enabled any antivirus or content archiving settings for FTP, FTP sessions resume after a failover.

UDP, ICMP, and broadcast packet session failover

By default, even with session pickup enabled, the FGCP does not maintain a session table for UDP, ICMP, or broadcast packets. So the cluster does not specifically support failover of these packets.

Some UDP traffic can continue to flow through the cluster after a failover. This can happen if, after the failover, a UDP packet that is part of an already established communication stream matches a security policy. Then a new session will be created and traffic will flow. So after a short interruption, UDP sessions can appear to have failed over. However, this may not be reliable for the following reasons:

- UDP packets in the direction of the security policy must be received before reply packets can be accepted. For example, if a port1 -> port2 policy accepts UDP packets, UDP packets received at port2 destined for the network connected to port1 will not be accepted until the policy accepts UDP packets at port1 that are destined for the network connected to port2. So, if a user connects from an internal network to the internet and starts receiving UDP packets from the internet (for example streaming media), after a failover the user will not receive any more UDP packets until the user re-connects to the internet site.
- UDP sessions accepted by NAT policies will not resume after a failover because NAT will usually give the new session a different source port. So only traffic for UDP protocols that can handle the source port changing during a session will continue to flow.

You can however, enable session pickup for UDP and ICMP packets by enabling session pickup for TCP sessions and then enabling session pickup for connectionless sessions:

```
config system ha
    set session-pickup enable
    set session-pickup-connectionless enable
end
```

This configuration causes the cluster units to synchronize UDP and ICMP session tables and if a failover occurs UDP and ICMP sessions are maintained.

SIP session failover

If session pickup is enabled, the FGCP supports SIP session failover (also called stateful failover) for active-passive HA.

SIP session failover replicates SIP states to all cluster units. If an HA failover occurs, all in-progress SIP calls (setup complete) and their RTP flows are maintained and the calls will continue after the failover with minimal or no interruption.

SIP calls being set up at the time of a failover may lose signaling messages. In most cases the SIP clients and servers should use message retransmission to complete the call setup after the failover has completed. As a result, SIP users may experience a delay if their calls are being set up when an HA failover occurs. But in most cases the call setup should be able to continue after the failover.

FortiOS Carrier GTP session failover

FortiOS Carrier HA supports GTP session failover. The primary unit synchronizes the GTP tunnel state to all cluster units after the GTP tunnel setup is completed. After the tunnel setup is completed, GTP sessions use UDP and HA does not synchronize UDP sessions to all cluster units. However, similar to other UDP sessions, after a failover, since the new primary unit will have the GTP tunnel state information, GTP UDP sessions using the same tunnel can continue to flow with some limitations.

The limitation on packets continuing to flow is that there has to be a security policy to accept the packets. For example, if the FortiOS Carrier unit has an internal to external security policy, GTP UDP sessions using an established tunnel that are received by the internal interface are accepted by the security policy and can continue to flow. However, GTP UDP packets for an established tunnel that are received at the external interface cannot flow until packets from the same tunnel are received at the internal interface.

If you have bi-directional policies that accept GTP UDP sessions then traffic in either direction that uses an established tunnel can continue to flow after a failover without interruption.

SSL offloading and HTTP multiplexing session failover

SSL offloading and HTTP multiplexing are both enabled from firewall virtual IPs and firewall load balancing. Similar to the features applied by security profile, SSL offloading and HTTP multiplexing requires the FortiGate to maintain very large amounts of internal state information for each session. Sessions accepted by security policies containing virtual IPs or virtual servers with SSL offloading or HTTP multiplexing enabled do not resume after a failover.

Active-active HA subordinate units sessions can resume after a failover

In an active-active cluster, subordinate units process sessions. After a failover, all cluster units that are still operating may be able to continue processing the sessions that they were processing before the failover. These sessions are maintained because after the failover the new primary unit uses the HA session table to continue to send session packets to the cluster units that were processing the sessions before the failover. Cluster units maintain their own information about the sessions that they are processing and this information is not affected by the failover. In this way, the cluster units that are still operating can continue processing their own sessions without loss of data.

The cluster keeps processing as many sessions as it can. But some sessions can be lost. Depending on what caused the failover, sessions can be lost in the following ways:

- A cluster unit fails (the primary unit or a subordinate unit). All sessions that were being processed by that cluster unit are lost.
- A link failure occurs. All sessions that were being processed through the network interface that failed are lost.

This mechanism for continuing sessions is not the same as session failover because:

- Only the sessions that can be maintained are maintained.
- The sessions are maintained on the same cluster units and not re-distributed.
- Sessions that cannot be maintained are lost.

Session failover limitations for sessions terminated by the cluster

This section contains information about session failover for communication sessions terminated by the cluster. Sessions terminated by the cluster include management sessions as well as IPsec and SSL VPN, WAN Optimization and so on between the cluster and a client.

In general, most sessions terminated by the cluster have to be restarted after a failover. There are some exceptions though, for example, the FGCP provides failover for IPsec and SSL VPN sessions terminated by the cluster.

The session pickup setting does not affect session failover for sessions terminated by the cluster. Also other cluster settings such as active-active or active-passive mode do not affect session failover for sessions terminated by the cluster.

Protocol	Session Failover?
Administrative or management connections such as connecting to the GUI or CLI, SNMP, syslog, communication with FortiManager, FortiAnalyzer and so on.	Not supported, sessions have to be restarted.
Explicit web proxy, WCCP, WAN Optimization and Web Caching.	Not supported, sessions have to be restarted. (Explicit web proxy, explicit FTP proxy, WCCP, WAN optimization and Web Caching session failover on page 1574)
IPsec VPN tunnels terminating at the FortiGate	Supported. SAs and related IPsec VPN tunnel data is synchronized to cluster members. (Synchronizing IPsec VPN SAs on page 1575)
SSL VPN tunnels terminating at the FortiGate	Partially supported. Sessions are not synchronized and have to be restarted. Authentication failover and cookie failover is supported. Once the client restarts the session they shouldn't have to re-authenticate. (SSL VPN session failover and SSL VPN authentication failover on page 1575)
PPTP and L2TP VPN terminating at the FortiGate	Not supported, sessions have to be restarted.

Explicit web proxy, explicit FTP proxy, WCCP, WAN optimization and Web Caching session failover

Explicit web proxy, explicit FTP proxy, WCCP, WAN optimization and web caching sessions all require the FortiGate to maintain very large amounts of internal state information for each session. This information is not maintained and these sessions do not resume after a failover.

The active-passive HA clustering is recommended for WAN optimization. All WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions.

Also, Web cache and byte cache databases are only stored on the primary unit. These databases are not synchronized to the cluster. So, after a failover, the new primary unit must rebuild its web and byte caches. As well, the new primary unit cannot connect to a SAS partition that the failed primary unit used.

Rebuilding the byte caches can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGates that it is participating with in WAN optimization tunnels.

SSL VPN session failover and SSL VPN authentication failover

Session failover is not supported for SSL VPN tunnels. However, authentication failover is supported for the communication between the SSL VPN client and the FortiGate. This means that after a failover, SSL VPN clients can re-establish the SSL VPN session between the SSL VPN client and the FortiGate without having to authenticate again.

However, all sessions inside the SSL VPN tunnel that were running before the failover are stopped and have to be restarted. For example, file transfers that were in progress would have to be restarted. As well, any communication sessions with resources behind the FortiGate that are started by an SSL VPN session have to be restarted.

To support SSL VPN cookie failover, when an SSL VPN session starts, the FGCP distributes the cookie created to identify the SSL VPN session to all cluster units.

PPTP and L2TP VPN sessions

PPTP and L2TP VPNs are supported in HA mode. For a cluster you can configure PPTP and L2TP settings and you can also add security policies to allow PPTP and L2TP pass through. However, the FGCP does not provide session failover for PPTP or L2TP. After a failover, all active PPTP and L2TP sessions are lost and must be restarted.

Synchronizing IPsec VPN SAs

The FGCP synchronizes IPsec security associations (SAs) between cluster members so that if a failover occurs, the cluster can resume IPsec sessions without having to establish new SAs. The result is improved failover performance because IPsec sessions are not interrupted to establish new SAs. Also, establishing a large number of SAs can reduce cluster performance.

The FGCP implements slightly different synchronization mechanisms for IKEv1 and IKEv2.

Synchronizing SAs for IKEv1

When an SA is synchronized to the subordinate units, the sequence number is set to the maximum sequence number. After a failover, all inbound traffic that connects with the new primary unit and uses the SA will be accepted without needing to re-key. However, first outbound packet to use the SA causes the sequence number to overflow and so causes the new primary unit to re-key the SA.

Please note the following:

- The cluster synchronizes all IPsec SAs.
- IPsec SAs are not synchronized until the IKE process has finished synchronizing the ISAKMP SAs. This is required in for dialup tunnels since it is the synchronizing of the ISAKMP SA that creates the dialup tunnel.
- A dialup interface is created as soon as the phase 1 is complete. This ensures that the when HA synchronizes phase 1 information the dialup name is included.
- If the IKE process re-starts for any reason it deletes any dialup tunnels that exist. This forces the peer to re-key them.
- IPsec SA deletion happens immediately. Routes associated with a dialup tunnel that is being deleted are cleaned up synchronously as part of the delete, rather than waiting for the SA hard-expiry.
- The FGCP does not sync the IPsec tunnel MTU from the primary unit to the subordinate units. This means that after HA failover if the first packet received by the FortiGate arrives after the HA route has been deleted and before the new route is added and the packet is larger than the default MTU of 1024 then the FortiGate sends back an

ICMP fragmentation required. However, as soon as routing is re-established then the MTU will be corrected and traffic will flow.

Synchronizing SAs for IKEv2

Due to the way the IKEv2 protocol is designed the FGCP cannot use exactly the same solution that is used for synchronizing IKEv1 SAs, though it is similar.

For IKEv2, like IKEv1, the FGCP synchronizes IKE and ISAKMP SAs from the primary unit to the subordinate units. However, for IKEv2 the FGCP cannot actually use this IKE SA to send/receive IKE traffic because IKEv2 includes a sequence number in every IKE message and thus it would require synchronizing every message to the subordinate units to keep the sequence numbers on the subordinate units up to date.

Instead, the FGCP synchronizes IKEv2 Message IDs. This Message ID Sync allows IKEv2 to re-negotiate send and receive message ID counters after a failover. By doing this, the established IKE SA can remain up, instead of re-negotiating.

The `diagnose vpn ike stats` command shows statistics for the number of HA messages sent/received for IKEv2. The output of this command includes a number of fields prefixed with `ha` that contain high availability related-data. For example:

```
.
.
.
ha.resync: 0
ha.vike.sync: 0
ha.conn.sync: 0
ha.sync.tx: 1
ha.sync.rx: 0
ha.sync.rx.len.bad: 0
.
.
.
```

WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended HA configuration for WAN optimization is active-passive mode. Also, when the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions. HA also does not support WAN optimization session failover.

In a cluster, the primary unit only stores web cache and byte cache databases. These databases are not synchronized to the subordinate units. So, after a failover, the new primary unit must rebuild its web and byte caches. As well, the new primary unit cannot connect to a SAS partition that the failed primary unit used.

Rebuilding the byte caches can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGates that it is participating with in WAN optimization tunnels.

HA and load balancing

FGCP active-active (a-a) load balancing distributes network traffic among all of the units in a cluster. Load balancing can improve cluster performance because the processing load is shared among multiple cluster units.

This chapter describes how active-active load balancing works and provides detailed active-active HA NAT/Route and transparent mode packet flow descriptions.

Load balancing overview

FGCP active-active HA uses a technique similar to unicast load balancing in which the primary unit is associated with the cluster HA virtual MAC addresses and cluster IP addresses. The primary unit is the only cluster unit to receive packets sent to the cluster. The primary unit then uses a load balancing schedule to distribute sessions to all of the units in the cluster (including the primary unit). Subordinate unit interfaces retain their actual MAC addresses and the primary unit communicates with the subordinate units using these MAC addresses. Packets exiting the subordinate units proceed directly to their destination and do not pass through the primary unit first.

By default, active-active HA load balancing distributes proxy-based security profile processing to all cluster units. Proxy-based security profile processing is CPU and memory-intensive, so FGCP load balancing may result in higher throughput because resource-intensive processing is distributed among all cluster units.

Proxy-based security profile processing that is load balanced includes proxy-based virus scanning, proxy-based web filtering, proxy-based email filtering, and proxy-based data leak prevention (DLP) of HTTP, FTP, IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, IM, and NNTP, sessions accepted by security policies.

Other features enabled in security policies such as Endpoint security, traffic shaping and authentication have no effect on active-active load balancing.

You can also enable `load-balance-all` to have the primary unit load balance all TCP sessions. Load balancing TCP sessions increases overhead and may actually reduce performance so it is disabled by default. You can also enable `load-balance-udp` to have the primary unit load balance all UDP sessions. Load balancing UDP sessions also increases overhead so it is also disabled by default.

NP4 and NP6 processors can also offload and accelerate load balancing.

During active-active HA load balancing the primary unit uses the configured load balancing schedule to determine the cluster unit that will process a session. The primary unit stores the load balancing information for each load balanced session in the cluster load balancing session table. Using the information in this table, the primary unit can then forward all of the remaining packets in each session to the appropriate cluster unit. The load balancing session table is synchronized among all cluster units.

HTTPS, ICMP, multicast, and broadcast sessions are never load balanced and are always processed by the primary unit. IPS, Application Control, flow-based virus scanning, flow-based web filtering, flow-based DLP, flow-based email filtering, VoIP, IM, P2P, IPsec VPN, HTTPS, SSL VPN, HTTP multiplexing, SSL offloading, WAN optimization, explicit web proxy, and WCCP sessions are also always processed only by the primary unit.

In addition to load balancing, active-active HA also provides the same session, device and link failover protection as active-passive HA. If the primary unit fails, a subordinate unit becomes the primary unit and resumes operating the cluster.

Active-active HA also maintains as many load balanced sessions as possible after a failover by continuing to process the load balanced sessions that were being processed by the cluster units that are still operating. See [Active-active HA subordinate units sessions can resume after a failover on page 1](#) for more information.

Load balancing schedules

The load balancing schedule controls how the primary unit distributes packets to all cluster units. You can select from the following load balancing schedules.

Schedule	Description
None	No load balancing. Select None when the cluster interfaces are connected to load balancing switches. If you select None, the Primary unit does not load balance traffic and the subordinate units process incoming traffic that does not come from the Primary unit. For all other load balancing schedules, all traffic is received first by the Primary unit, and then forwarded to the subordinate units. The subordinate units only receive and process packets sent from the primary unit.
Hub	Load balancing if the cluster interfaces are connected to a hub. Traffic is distributed to cluster units based on the source IP and destination IP of the packet.
Least-Connection	If the cluster units are connected using switches, select Least Connection to distribute network traffic to the cluster unit currently processing the fewest connections.
Round-Robin	If the cluster units are connected using switches, select Round-Robin to distribute network traffic to the next available cluster unit.
Weighted Round-Robin	Similar to round robin, but weighted values are assigned to each of the units in a cluster based on their capacity and on how many connections they are currently processing. For example, the primary unit should have a lower weighted value because it handles scheduling and forwards traffic. Weighted round robin distributes traffic more evenly because units that are not processing traffic will be more likely to receive new connections than units that are very busy.
Random	If the cluster units are connected using switches, select Random to randomly distribute traffic to cluster units.
IP	Load balancing according to IP address. If the cluster units are connected using switches, select IP to distribute traffic to units in a cluster based on the source IP and destination IP of the packet.
IP Port	Load balancing according to IP address and port. If the cluster units are connected using switches, select IP Port to distribute traffic to units in a cluster based on the source IP, source port, destination IP, and destination port of the packet.

Once a packet has been propagated to a subordinate unit, all packets are part of that same communication session are also propagated to that same subordinate unit. Traffic is distributed according to communication session, not just according to individual packet.

Any subordinate unit that receives a forwarded packet processes it, without applying load balancing. Note that subordinate units are still considered to be active, because they perform routing, virus scanning, and other

FortiGate tasks on their share of the traffic. Active subordinate units also share their session and link status information with all cluster units. The only things that active members do not do is make load balancing decisions.

Even though the primary unit is responsible for the load balancing process, the primary unit still acts like a FortiGate in that it processes packets, performing, routing, firewall, virus scanning, and other FortiGate tasks on its share of the traffic. Depending on the load balancing schedule used, the primary unit may assign itself a smaller share of the total load.

More about active-active failover

If a subordinate unit fails, the primary unit re-distributes the sessions that the subordinate was processing among the remaining active cluster members. If the primary unit fails, the subordinate units negotiate to select a new primary unit. The new primary unit continues to distribute packets among the remaining active cluster units.

Failover works in a similar way if the cluster consists of only two units. If the primary unit fails the subordinate unit negotiates and becomes the new primary unit. If the subordinate unit fails, the primary unit processes all traffic. In both cases, the single remaining unit continues to function as a primary unit, maintaining the HA virtual MAC address for all of its interfaces.

HTTPS sessions, active-active load balancing, and proxy servers

To prevent HTTPS web filtering problems active-active HA does not load balance HTTPS sessions. The FortiGate identifies HTTPS sessions as all sessions received on the HTTPS TCP port. The default HTTPS port is 443. You can go to **Policy & Objects > Policy > SSL/SSH Inspection** to use a custom port for HTTPS sessions. If you change the HTTPS port, the FGCP stops load balancing all sessions that use the custom HTTPS port.

Normally you would not change the HTTPS port. However, if your network uses a proxy server for HTTPS traffic you may have to change to the custom HTTPS port used by your proxy server. If your network uses a proxy server you might also use the same port for both HTTP and HTTPS traffic. In this case you would configure the FortiGate to use custom ports for both HTTP and HTTPS traffic. Go to **Policy & Objects > Policy > Proxy Options** to use a custom port for HTTP.

Using the same port for HTTP and HTTPS traffic can cause problems with active-active clusters because active-active clusters always load balance HTTP traffic. If both HTTP and HTTPS use the same port, the active-active cluster cannot differentiate between HTTP and HTTPS traffic and will load balance both.

As mentioned above, load balancing HTTPS traffic may cause problems with HTTPS web filtering. To avoid this problem, you should configure your proxy server to use different ports for HTTP and HTTPS traffic. Then configure your cluster to also use different ports for HTTP and HTTPS.

Selecting a load balancing schedule

You can select the load balancing schedule when initially configuring the cluster and you can change the load balancing schedule at any time while the cluster is operating without affecting cluster operation.

You can select a load balancing schedule from the CLI. Use the following command to select a load balancing schedule:

```
config system ha
  set schedule {hub | ip | ipport | leastconnection | none | random | round-robin
    | weight-round-robin}
end
```

Load balancing TCP and UDP sessions

You can use the following command to configure the cluster to load balance TCP sessions in addition to security profile sessions.

```
config system ha
    set load-balance-all enable
end
```

Enabling `load-balance-all` to add load balancing of TCP sessions may not improve performance because the cluster requires additional overhead to load balance sessions. Load balancing a TCP session usually requires about as much overhead as just processing it. On the other hand, TCP load balancing performance may be improved if your FortiGate includes NP4 or NP6 processors.

You can enable `load-balance-all` and monitor network performance to see if it improves. If performance is not improved, you might want to change the HA mode to active-passive since active-active HA is not providing any benefit.

On some FortiGate models you can use the following command to also load balance UDP sessions:

```
config system ha
    set load-balance-udp enable
end
```

Similar to load balancing TCP sessions, load balancing UDP sessions may also not improve performance. Also UDP load balancing performance may be improved with NP4 and NP6 processors.

Using NP4 or NP6 processors to offload load balancing

FortiGates that include NP4 and NP6 network processors can provide hardware acceleration for active-active HA cluster by offloading load balancing from the primary unit CPU. Network processors are especially useful when load balancing TCP and UDP sessions.

The first packet of every new session is received by the primary unit and the primary unit uses its load balancing schedule to select the cluster unit that will process the new session. This information is passed back to the network processor and all subsequent packets of the same sessions are offloaded to the network processor which sends the packet directly to a subordinate unit. Load balancing is effectively offloaded from the primary unit to the network processor resulting in a faster and more stable active-active cluster.

To take advantage of network processor load balancing acceleration, connect the cluster unit interfaces with network processors to the busiest networks. Connect other interfaces to less busy networks. No special FortiOS or HA configuration is required. Network processor acceleration of active-active HA load balancing is supported for any active-active HA configuration or active-active HA load balancing schedule.

Configuring weighted-round-robin weights

You can configure weighted round-robin load balancing for a cluster and configure the static weights for each of the cluster units according to their priority in the cluster. When you set `schedule` to `weight-round-robin` you can use the `weight` option to set the static weight of each cluster unit. The static weight is set according to the priority of each unit in the cluster. A FortiGate HA cluster can contain up to four FortiGates so you can set up to 4 static weights.

The priority of a cluster unit is determined by its device priority, the number of monitored interfaces that are functioning, its age in the cluster and its serial number. Priorities are used to select a primary unit and to set the priorities of all of the subordinate units. Thus the priority of a cluster unit can change depending on configuration

settings, link failures and so on. Since weights are also set using this priority, the weights are independent of specific cluster units but do depend on the role of the each unit in the cluster.

You can use the following command to display the relative priorities of the units in a cluster. The cluster unit serial numbers and their priorities are listed in the last few lines of the command output. This example shows a cluster of three FortiGates:

```
get system ha status
.
.
.
Slave : FG-5KD3914800284, operating cluster index = 1
Master: FG-5KD3914800344, operating cluster index = 0
Slave : FG-5KD3914800353, operating cluster index = 2
```

The primary unit always has the highest priority and the subordinate units have lower priorities.

The default static weight for each cluster unit is 40. This means that sessions are distributed evenly among all cluster units. You can use the `set weight` command to change the static weights of cluster units to distribute sessions to cluster units depending on their priority in the cluster. The weight can be between 0 and 255. Increase the weight to increase the number of connections processed by the cluster unit with that priority.

You set the weight for each unit separately. For the example cluster of 3 FortiGates you can set the weight for each unit as follows:

```
config system ha
  set mode a-a
  set schedule weight-round-robin
  set weight 0 5
  set weight 1 10
  set weight 2 15
end
```

If you enter the `get` command to view the HA configuration the output for `weight` would be:

```
weight 5 10 15 40 40 40 40 40 40 40 40 40 40 40 40
```

This configuration has the following results if the output of the `get system ha status` command is that shown above:

- The first five connections are processed by the primary unit (priority 0, weight 5).
- The next 10 connections are processed by the first subordinate unit (priority 1, weight 10)
- The next 15 connections are processed by the second subordinate unit (priority 2, weight 15)

Dynamically optimizing weighted load balancing according to how busy cluster units are

In conjunction with using static weights to load balance sessions among cluster units you can configure a cluster to dynamically load balance sessions according to individual cluster unit CPU usage, memory usage, and number of HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy-based security profile sessions. If any of these system loading indicators increases above configured thresholds, weighted load balancing dynamically sends fewer new sessions to the busy unit until it recovers.

High CPU or memory usage indicates that a unit is under increased load and may not be able to process more sessions. HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy use are also good indicators of how busy a cluster unit is, since processing high numbers of these proxy sessions can quickly reduce overall cluster unit performance.

For example, you can set a CPU usage high watermark threshold. When a cluster unit reaches this high watermark threshold fewer sessions are sent to it. With fewer sessions to process the cluster unit's CPU usage should fall back to the low watermark threshold. When the low watermark threshold is reached the cluster resumes normal load balancing of sessions to the cluster unit.

You can set individual high and low watermark thresholds and weights for CPU usage, memory usage, and for the number of HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy sessions.

The CPU usage, memory usage, and proxy weights determine how the cluster load balances sessions when a high watermark threshold is reached and also affect how the cluster load balances sessions when multiple cluster units reach different high watermark thresholds at the same time. For example, you might be less concerned about a cluster unit reaching the memory usage high watermark threshold than reaching the CPU usage high watermark threshold. If this is the case you can set the weight lower for memory usage. Then, if one cluster unit reaches the CPU usage high watermark threshold and a second cluster unit reaches the memory usage high watermark threshold the cluster will load balance more sessions to the cluster unit with high memory usage and fewer sessions to the cluster unit with high CPU usage. As a result, reaching the CPU usage high watermark will have a greater affect on how sessions are redistributed than reaching the memory usage high watermark.

When a high watermark threshold is reached, the corresponding weight is subtracted from the static weight of the cluster unit. The lower the weight the fewer the number of sessions that are load balanced to that unit.

Subsequently when the low watermark threshold is reached, the static weight of the cluster unit returns to its configured value. For the weights to all be effective the weights assigned to the load indicators should usually be lower than or equal to the static weights assigned to the cluster units.

Use the following command to set thresholds and weights for CPU and memory usage and HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy sessions:

```
config system ha
  set mode a-a
  set schedule weight-round-robin
  set cpu-threshold <weight> <low> <high>
  set memory-threshold <weight> <low> <high>
  set http-proxy-threshold <weight> <low> <high>
  set ftp-proxy-threshold <weight> <low> <high>
  set imap-proxy-threshold <weight> <low> <high>
  set nntp-proxy-threshold <weight> <low> <high>
  set pop3-proxy-threshold <weight> <low> <high>
  set smtp-proxy-threshold <weight> <low> <high>
end
```

For each option, the weight range is 0 to 255 and the default weight is 5. The low and high watermarks are a percent (0 to 100). The default low and high watermarks are 0 which means they are disabled. The default configuration when weighted load balancing is enabled looks like the following:

```
config system ha
  set mode a-a
  set schedule weight-round-robin
  set cpu-threshold 5 0 0
  set memory-threshold 5 0 0
  set http-proxy-threshold 5 0 0
  set ftp-proxy-threshold 5 0 0
  set imap-proxy-threshold 5 0 0
  set nntp-proxy-threshold 5 0 0
  set pop3-proxy-threshold 5 0 0
  set smtp-proxy-threshold 5 0 0
end
```

When you first enable HA weighted load balancing, the weighted load balancing configuration is synchronized to all cluster units and each cluster unit has the default configuration shown above. Changes to the CPU, memory, HTTP, FTP, IMAP, NNTP, POP3, and SMTP proxy thresholds and low and high watermarks must be made for each cluster unit and are not synchronized to the other cluster units.

When you configure them, the high watermarks must be greater than their corresponding low watermarks.

For CPU and memory usage the low and high watermarks are compared with the percentage CPU and memory use of the cluster unit. For each of the proxies the high and low watermarks are compared to a number that represents percent of the max number of proxy sessions being used by a proxy. This number is calculated using the formula:

$$\text{proxy usage} = (\text{current sessions} * 100) / \text{max sessions}$$

where:

`current sessions` is the number of active sessions for the proxy type.

`max sessions` is the session limit for the proxy type. The session limit depends on the FortiGate and its configuration.

You can use the following command to display the maximum and current number of sessions for a proxy:

```
get test {ftpd | http | imap | nntp | pop3 | smtp} 4
```

You can use the following command to display the maximum number of sessions and the current number of sessions for all of the proxies:

```
get test proxyworker 4
```

The command output includes lines similar to the following:

```
get test http 4
HTTP Common
Current Connections          5000/8032
```

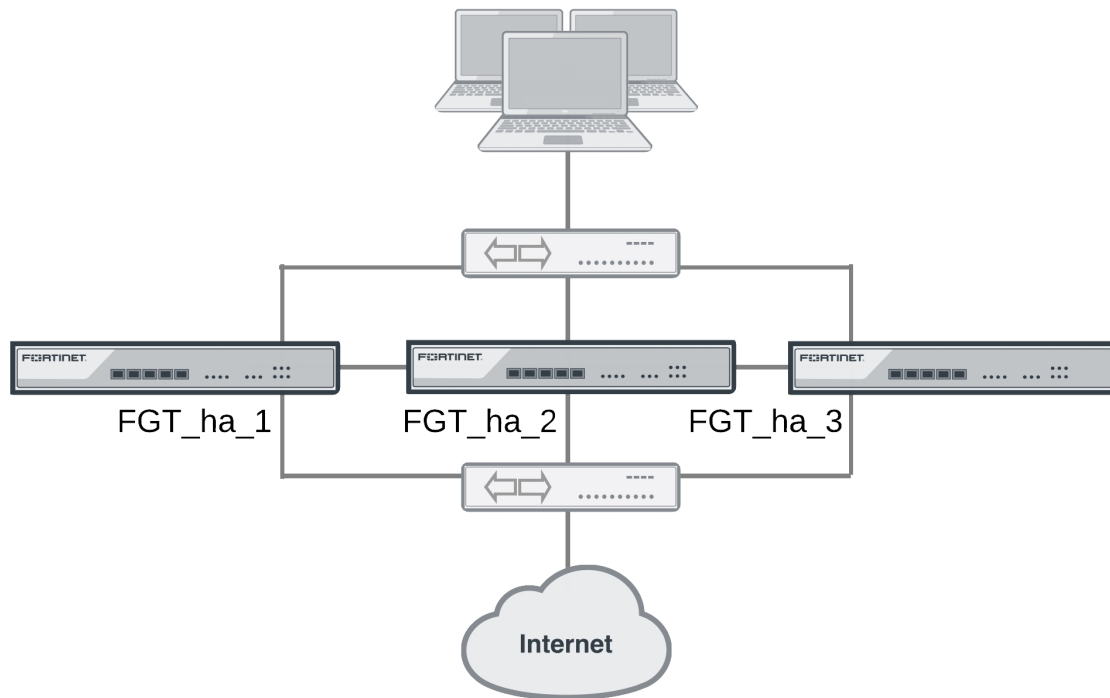

In the example, 5000 is the current number of proxy connections being used by HTTP and 8032 is the maximum number of proxy sessions allowed. For this example the proxy usage would be:

```
proxy usage = (5000 * 100) / 8032
proxy usage = 62%
```

Example weighted load balancing configuration

Consider a cluster of three FortiGates with host names FGT_ha_1, FGT_ha_2, and FGT_ha_3 as shown below. This example describes how to configure weighted load balancing settings for CPU and memory usage for the cluster and then to configure HTTP and POP3 proxy weights to send most HTTP and POP3 proxy sessions to different cluster units.

Example HA weighted load balancing configuration

Connect to the cluster CLI and use the following command to set the CPU usage threshold weight to 30, low watermark to 60, and high watermark to 80. This command also sets the memory usage threshold weight to 10, low watermark to 60, and high watermark to 90.

```

config system ha
    set mode a-a
    set schedule weight-round-robin
    set cpu-threshold 30 60 80
    set memory-threshold 10 60 90
end
  
```

The static weights for the cluster units remain at the default values of 40. Since this command changes the mode to `a-a` and the schedule to `weight-round-robin` for the first time, the weight settings are synchronized to all cluster units.

As a result of this configuration, if the CPU usage of any cluster unit (for example, FGT_ha_1) reaches 80% the static weight for that cluster unit is reduced from 40 to 10 and only 10 of every 120 new sessions are load balanced to this cluster unit. If the memory usage of FGT_ha_1 also reaches 90% the static weight further reduces to 0 and no new sessions are load balanced to FGT_ha_1. Also, if the memory usage of FGT_ha_2 reaches 90% the static weight of FGT_ha_2 reduces to 30 and 30 of every 120 new sessions are load balanced to FGT_ha_2.

Now that you have established the weight load balancing configuration for the entire cluster you can monitor the cluster to verify that processing gets distributed evenly to all cluster units. From the GUI you can go to **System > HA > View HA Statistics** and see the CPU usage, active sessions, memory usage and other statistics for all of the cluster units. If you notice that one cluster unit is more or less busy than others you can adjust the dynamic weights separately for each cluster unit.

For example, in some active-active clusters the primary unit may tend to be busier than other cluster units because in addition to processing sessions the primary unit also receives all packets sent to the cluster and performs load balancing to distribute the sessions to other cluster units. To reduce the load on the primary unit you could reduce the CPU and memory usage high watermark thresholds for the primary unit so that fewer sessions are distributed to the primary unit. You could also reduce the primary unit's high watermark setting for the proxies to distribute more proxy sessions to other cluster units.

This would only be useful if you are using device priorities and override settings to make sure the same unit always becomes the primary unit. See [Controlling primary unit selection using device priority and override on page 1395](#).

If the example cluster is configured for FGT_ha_2 to be the primary unit, connect to the FGT_ha_2's CLI and enter the following command to set CPU usage, memory usage, and proxy usage high watermark thresholds lower.

```
config system ha
  set cpu-threshold 30 60 70
  set memory-threshold 30 60 70
  set http-proxy-threshold 30 60 70
  set ftp-proxy-threshold 30 60 70
  set imap-proxy-threshold 30 60 70
  set nntp-proxy-threshold 30 60 70
  set pop3-proxy-threshold 30 60 70
  set smtp-proxy-threshold 30 60 70
end
```

As a result, when any of these factors reaches 70% on the primary unit, fewer sessions will be processed by the primary unit, preventing the number of sessions being processed from rising.

NAT/Route mode active-active cluster packet flow

This section describes an example of how packets are load balanced and how failover occurs in an active-active HA cluster running in NAT/Route mode. In the example, the NAT/Route mode cluster acts as the internet firewall for a client computer's internal network. The client computer's default route points at the IP address of the cluster internal interface. The client connects to a web server on the internet. Internet routing routes packets from the cluster external interface to the web server, and from the web server to the cluster external interface.

In NAT/Route mode, eight MAC addresses are involved in active-active communication between the client and the web server when the primary unit load balances packets to the subordinate unit:

- Internal virtual MAC address (MAC_V_int) assigned to the primary unit internal interface,
- External virtual MAC address (MAC_V_ext) assigned to the primary unit external interface,
- Client MAC address (MAC_Client),
- Server MAC address (MAC_Server),
- Primary unit original internal MAC address (MAC_P_int),
- Primary unit original external MAC address (MAC_P_ext),
- Subordinate unit internal MAC address (MAC_S_int),
- Subordinate unit external MAC address (MAC_S_ext).

In NAT/Route mode, the HA cluster works as a gateway when it responds to ARP requests. Therefore, the client and server only know the gateway MAC addresses. The client only knows the cluster internal virtual MAC address (MAC_V_int) and the server only knows the cluster external virtual MAC address (MAC_V_ext).

NAT/Route mode active-active packet flow

Packet flow from client to web server

1. The client computer requests a connection from 10.11.101.10 to 172.20.120.130.
2. The default route on the client computer recognizes 10.11.101.100 (the cluster IP address) as the gateway to the external network where the web server is located.
3. The client computer issues an ARP request to 10.11.101.100.
4. The primary unit intercepts the ARP request, and responds with the internal virtual MAC address (MAC_V_int) which corresponds to its IP address of 10.11.101.100.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	172.20.120.130	MAC_V_int

6. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit internal interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit internal interface.

IP address	MAC address
------------	-------------

Source	10.11.101.10	MAC_P_int
Destination	172.20.120.130	MAC_S_int

7. The subordinate unit recognizes that the packet has been forwarded from the primary unit and processes it.
8. The subordinate unit forwards the packet from its external interface to the web server.

	IP address	MAC address
Source	172.20.120.141	MAC_S_ext
Destination	172.20.120.130	MAC_Server

9. The primary unit forwards further packets in the same session to the subordinate unit.
10. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

Packet flow from web server to client

1. When the web server responds to the client's packet, the cluster external interface IP address (172.20.120.141) is recognized as the gateway to the internal network.
2. The web server issues an ARP request to 172.20.120.141.
3. The primary unit intercepts the ARP request, and responds with the external virtual MAC address (MAC_V_ext) which corresponds its IP address of 172.20.120.141.
4. The web server then sends response packets to the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_Server
Destination	172.20.120.141	MAC_V_ext

5. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit external interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_P_ext
Destination	172.20.120.141	MAC_S_ext

6. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.
7. The subordinate unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	172.20.120.130	MAC_S_int
Destination	10.11.101.10	MAC_Client

8. The primary unit forwards further packets in the same session to the subordinate unit.
9. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails, the subordinate unit negotiates to become the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC addresses.
The new primary unit has the same IP addresses and MAC addresses as the failed primary unit.
3. The new primary unit sends gratuitous ARP packets to the 10.10.101.0 network to associate its internal IP address with the internal virtual MAC address.
4. The new primary unit sends gratuitous ARP packets to the 172.20.120.0 network to associate its external IP address with the external virtual MAC address.
5. Traffic sent to the cluster is now received and processed by the new primary unit.

If there were more than two cluster units in the original cluster, the new primary unit would load balance packets to the remaining cluster members.

Transparent mode active-active cluster packet flow

This section describes an example of how packets are load balanced and how failover occurs in an active-active HA cluster running in transparent mode. The cluster is installed on an internal network in front of a mail server and the client connects to the mail server through the transparent mode cluster.

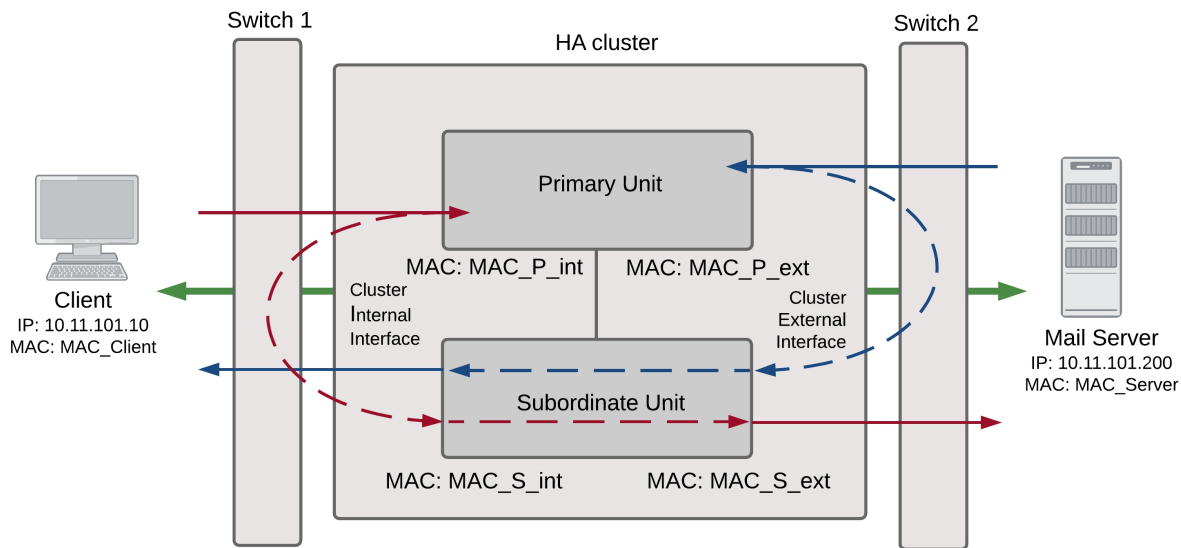

In transparent mode, six MAC addresses are involved in active-active communication between a client and a server when the primary unit load balances packets to the subordinate unit:

- Client MAC address (MAC_Client),
- Server MAC address (MAC_Server),
- Primary unit original internal MAC address (MAC_P_int),
- Primary unit original external MAC address (MAC_P_ext),
- Subordinate unit internal MAC address (MAC_S_int),
- Subordinate unit external MAC address (MAC_S_ext).

The HA virtual MAC addresses are not directly involved in communication between the client and the server. The client computer sends packets to the mail server and the mail server sends responses. In both cases the packets are intercepted and load balanced among cluster members.

The cluster's presence on the network and its load balancing are transparent to the client and server computers. The primary unit sends gratuitous ARP packets to Switch 1 that associate all MAC addresses on the network segment connected to the cluster external interface with the external virtual MAC address. The primary unit also sends gratuitous ARP packets to Switch 2 that associate all MAC addresses on the network segment connected to the cluster internal interface with the internal virtual MAC address. In both cases, this results in the switches sending packets to the primary unit interfaces.

Transparent mode active-active packet flow

Packet flow from client to mail server

1. The client computer requests a connection from 10.11.101.10 to 10.11.101.200.
2. The client computer issues an ARP request to 10.11.101.200.
3. The primary unit forwards the ARP request to the mail server.
4. The mail server responds with its MAC address (MAC_Server) which corresponds to its IP address of 10.11.101.200. The primary unit returns the ARP response to the client computer.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	10.11.101.200	MAC_Server

6. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit internal interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_P_int
Destination	10.11.101.200	MAC_S_int

7. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.
8. The subordinate unit forwards the packet from its external interface to the mail server.

	IP address	MAC address
Source	10.11.101.10	MAC_S_ext
Destination	10.11.101.200	MAC_Server

9. The primary unit forwards further packets in the same session to the subordinate unit.
10. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

Packet flow from mail server to client

1. To respond to the client computer, the mail server issues an ARP request to 10.11.101.10.
2. The primary unit forwards the ARP request to the client computer.
3. The client computer responds with its MAC address (MAC_Client) which corresponds to its IP address of 10.11.101.10. The primary unit returns the ARP response to the mail server.
4. The mail server's response packet reaches the primary unit external interface.

	IP address	MAC address
Source	10.11.101.200	MAC_Server
Destination	10.11.101.10	MAC_Client

5. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit external interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit external interface.

	IP address	MAC address
Source	10.11.101.200	MAC_P_ext
Destination	10.11.101.10	MAC_S_ext

6. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.
7. The subordinate unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	10.11.101.200	MAC_S_int
Destination	10.11.101.10	MAC_Client

8. The primary unit forwards further packets in the same session to the subordinate unit.
9. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails the subordinate unit negotiates to become the primary unit.
 2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC address.
 3. The new primary unit sends gratuitous ARP requests to switch 1 to associate its MAC address with the MAC addresses on the network segment connected to the external interface.
 4. The new primary unit sends gratuitous ARP requests to switch 2 to associate its MAC address with the MAC addresses on the network segment connected to the internal interface.
 5. Traffic sent to the cluster is now received and processed by the new primary unit.
- If there were more than two cluster units in the original cluster, the new primary unit would load balance packets to the remaining cluster members.

HA with FortiGate-VM and third-party products

This chapter provides information about operating FortiOS VM cluster and operating FortiGate clusters with third party products such as layer-2 and layer-3 switches.

FortiGate-VM for VMware HA configuration

If you want to combine two or more FortiGate-VM instances into a FortiGate Clustering Protocol (FGCP) High Availability (HA) cluster the VMware server's virtual switches used to connect the heartbeat interfaces must operate in promiscuous mode. This permits HA heartbeat communication between the heartbeat interfaces. HA heartbeat packets are non-TCP packets that use Ethertype values 0x8890, 0x8891, and 0x8893. All synchronization activity takes place over the HA heartbeat link using TCP/703 and UDP/703 packets. The FGCP uses link-local IPv4 addresses in the 169.254.0.x range for HA heartbeat interface IP addresses.

To enable promiscuous mode in VMware:

1. In the vSphere client, select your VMware server in the left pane and then select the **Configuration** tab in the right pane.
2. In **Hardware**, select **Networking**.
3. Select **Properties** of a virtual switch used to connect heartbeat interfaces.
4. In the **Properties** window left pane, select **vSwitch** and then select **Edit**.
5. Select the **Security** tab, set **Promiscuous Mode** to **Accept**, then select **OK**.
6. Select **Close**.

You must also set the virtual switches connected to other FortiGate interfaces to allow MAC address changes and to accept forged transmits. This is required because the FGCP sets virtual MAC addresses for all FortiGate interfaces and the same interfaces on the different VM instances in the cluster will have the same virtual MAC addresses.

To make the required changes in VMware:

1. In the vSphere client, select your VMware server in the left pane and then select the **Configuration** tab in the right pane.
2. In **Hardware**, select **Networking**.
3. Select **Properties** of a virtual switch used to connect FortiGate VM interfaces.
4. Set **MAC Address Changes** to **Accept**.
5. Set **Forged Transmits** to **Accept**.

FortiGate-VM for Hyper-V HA configuration

Promiscuous mode and support for MAC address spoofing is required for FortiGate-VM for Hyper-V to support FortiGate Clustering Protocol (FGCP) high availability (HA). By default the FortiGate-VM for Hyper-V has promiscuous mode enabled in the XML configuration file in the FortiGate-VM Hyper-V image. If you have problems with HA mode, confirm that this is still enabled.

In addition, because the FGCP applies virtual MAC addresses to FortiGate data interfaces and because these virtual MAC addresses mean that matching interfaces of different FortiGate-VM instances will have the same virtual MAC addresses you have to configure Hyper-V to allow MAC spoofing. But you should only enable MAC

spoofing for FortiGate-VM data interfaces. You should not enable MAC spoofing for FortiGate HA heartbeat interfaces.

With promiscuous mode enabled and the correct MAC spoofing settings you should be able to configure HA between two or more FortiGate-VM for Hyper-V instances.

Troubleshooting layer-2 switches

Issues may occur because of the way an HA cluster assigns MAC addresses to the primary unit. Two clusters with the same group ID cannot connect to the same switch and cannot be installed on the same network unless they are separated by a router.

Forwarding delay on layer 2 switches

You must ensure that if there is a switch between the FortiGate HA cluster and the network it is protecting and the switch has a forwarding delay (even if spanning tree is disabled) when one of its interfaces is activated then the forwarding delay should be set as low as possible. For example, some versions of Cisco IOS have a forwarding delay of 15 seconds even when spanning tree is disabled. If left at this default value then TCP session pickup can fail because traffic is not forwarded through the switch on HA failover.

Failover issues with layer-3 switches

After a failover, the new primary unit sends gratuitous ARP packets to refresh the MAC forwarding tables of the switches connected to the cluster. If the cluster is connected using layer-2 switches, the MAC forwarding tables (also called arp tables) are refreshed by the gratuitous ARP packets and the switches start directing packets to the new primary unit.

In some configurations that use layer-3 switches, after a failover, the layer-3 switches may not successfully re-direct traffic to the new primary unit. The possible reason for this is that the layer-3 switch might keep a table of IP addresses and interfaces and may not update this table for a relatively long time after the failover (the table is not updated by the gratuitous ARP packets). Until the table is updated, the layer-3 switch keeps forwarding packets to the now failed cluster unit. As a result, traffic stops and the cluster does not function.

As of the release date of this document, Fortinet has not developed a workaround for this problem. One possible solution would be to clear the forwarding table on the layer-3 switch.

The `config system ha link-failed-signal` command described in [Updating MAC forwarding tables when a link failover occurs on page 1553](#) can be used to resolve link failover issues similar to those described here.

Failover and attached network equipment

It normally takes a cluster approximately 6 seconds to complete a failover. However, the actual failover time may depend on how quickly the switches connected to the cluster interfaces accept the cluster MAC address update from the primary unit. If the switches do not recognize and accept the gratuitous ARP packets and update their MAC forwarding table, the failover time will increase.

Also, individual session failover depends on whether the cluster is operating in active-active or active-passive mode, and whether the content of the traffic is to be virus scanned. Depending on application behavior, it may take a TCP session a longer period of time (up to 30 seconds) to recover completely.

Ethertype conflicts with third-party switches

Some third-party network equipment may use packets with Ethertypes that are the same as the ethertypes used for HA heartbeat packets. For example, Cisco N5K/Nexus switches use Ethertype 0x8890 for some functions. When one of these switches receives Ethertype 0x8890 heartbeat packets from an attached cluster unit, the switch generates CRC errors and the packets are not forwarded. As a result, FortiGates connected with these switches cannot form a cluster.

In some cases, if the heartbeat interfaces are connected and configured so regular traffic flows but heartbeat traffic is not forwarded, you can change the configuration of the switch that connects the HA heartbeat interfaces to allow level2 frames with Ethertypes 0x8890, 0x8891, and 0x8893 to pass.

You can also use the following CLI commands to change the Ethertypes of the HA heartbeat packets:

```
config system ha
  set ha-eth-type <ha_ethertype_4-digit_hex>
  set hc-eth-type <hc_ethertype_4-digit_hex>
  set l2ep-eth-type <l2ep_ethertype_4-digit_hex>
end
```

For more information, see [Heartbeat packet Ethertypes on page 1527](#).

LACP, 802.3ad aggregation and third-party switches

If a cluster contains 802.3ad aggregated interfaces you should connect the cluster to switches that support configuring multiple Link Aggregation (LAG) groups.

The primary and subordinate unit interfaces have the same MAC address, so if you cannot configure multiple LAG groups a switch may place all interfaces with the same MAC address into the same LAG group; disrupting the operation of the cluster.

You can change the FortiGate configuration to prevent subordinate units from participating in LACP negotiation. For example, use the following command to do this for an aggregate interface named Port1_Port2:

```
config system interface
  edit Port1_Port2
    set lacp-ha-slave disable
  end
```

This configuration prevents the subordinate unit interfaces from sending or receiving packets. Resulting in the cluster not being able to operate in active-active mode. As well, failover may be slower because after a failover the new primary unit has to perform LACP negotiation before being able to process network traffic.

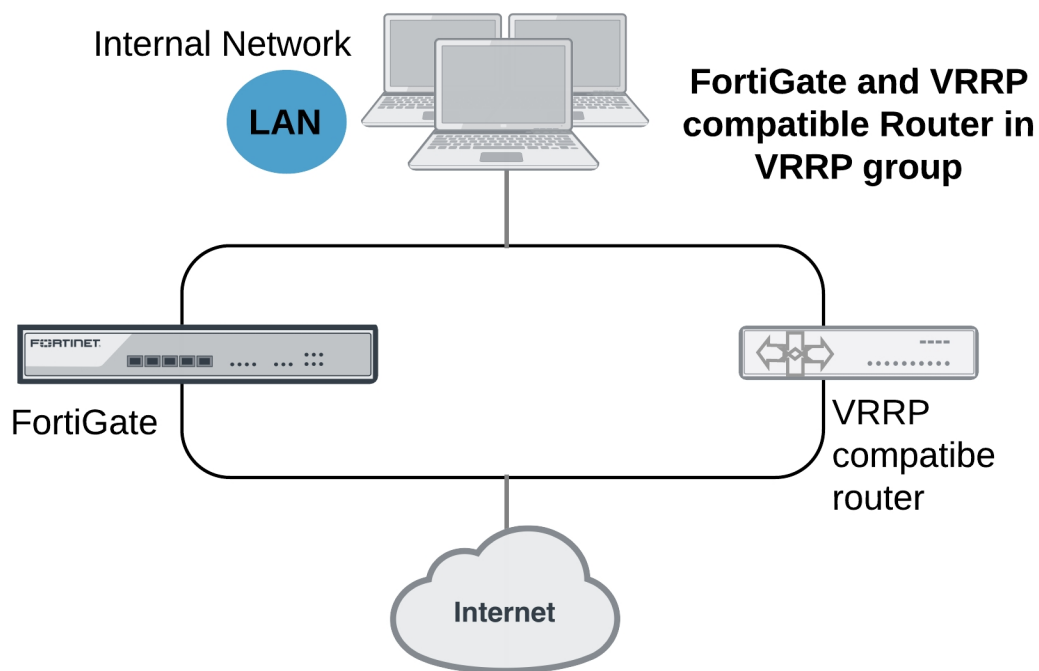

For more information, see [FGCP HA with 802.3ad aggregated interfaces on page 1436](#).

VRRP high availability

A Virtual Router Redundancy Protocol (VRRP) configuration can be used as a high availability solution to make sure that a network maintains connectivity with the internet (or with other networks) even if the default router for the network fails. Using VRRP, if a router or a FortiGate fails, all traffic to this router transparently fails over to another router or FortiGate that takes over the role of the router or FortiGate that failed. If the failed router or FortiGate is restored, it will once again take over processing traffic for the network. VRRP is described by [RFC 3768](#).

FortiOS supports VRRP versions 2 and 3 and you can set up VRRP groups that include multiple FortiGates and with other VRRP compatible routers. You can add different FortiGate models to the same VRRP group. FortiOS supports IPv4 and IPv6 VRRP and you can add IPv4 and IPv6 VRRP virtual routers to the same interface. FortiGates can also be quickly and easily integrated into a network that has already deployed a group of routers using VRRP.

Example VRRP configuration

The most common application of VRRP is to provide redundant default routers between an internal network and the internet. The default routers can be FortiGates and or any routers that support VRRP.

To set up VRRP:

1. Add a virtual VRRP router to the internal interface of each of the FortiGates and routers. This adds the FortiGates and routers to the same VRRP group.
2. Set the VRRP IP address of the group to the internal network default gateway IP address.

3. Give one of the VRRP group members the highest priority so it becomes the primary (or master) router and give the others lower priorities so they become backup routers.

During normal operations, all traffic from the internal network to the internet passes through the primary VRRP router. The primary router also sends VRRP advertisement messages to the backup routers. A backup router will not attempt to become a primary router while receiving these messages. If the primary router fails, the backup router with the highest priority becomes the new primary router after a short delay. During this delay the new primary router sends gratuitous ARP packets to the network to map the network's default route IP address to the new primary router's MAC address. All packets sent to the default route are now sent the new primary router. If the new primary router is a FortiGate, the network continues to benefit from FortiOS security features. If the new primary router is just a router, traffic continues to flow, but FortiOS security features are unavailable until the FortiGate is back on line.

If the backup router is a FortiGate, during a VRRP failover, as the FortiGate begins operating as the new primary router it will not have session information for all of the failed over in-progress sessions. So it would normally not be able to forward in-progress session traffic. To resolve this problem, immediately after a failover and for a short time (called the start time) the FortiGate acting as the new primary router operates with asymmetric routing enabled. This allows it to re-create all of the in-progress sessions and add them to its session table.

While operating with asymmetric routing enabled, the FortiGate cannot apply security functions. When the start-time ends the FortiGate disables asymmetric routing and returns to normal operation (including applying security functions).

Configuring VRRP

To configure VRRP you must configure two or more FortiGate interfaces or routers with the same virtual router ID and IP address. Then these FortiGates or routers can automatically join the same VRRP group. You must also assign priorities to each of the FortiGates or routers in the VRRP group. One of the FortiGates or routers must have the highest priority to become the primary (or master) router. The other FortiGates or routers in the group are assigned lower priorities and become backups. All of the routers in the VRRP group should have different priorities. If the primary router fails, VRRP automatically fails over to the router in the group with the next highest priority.

You configure VRRP from the FortiGate CLI by adding a VRRP virtual router to a FortiGate interface. You can add VRRP virtual routers to multiple FortiGate interfaces and you can add more than one virtual router to the same interface.

FortiOS supports VRRP with IPv6. You can add a VRRP virtual router to any FortiGate interface. You can also add IPv4 and IPv6 virtual routers to the same interface.

Adding an IPv4 VRRP virtual router to a FortiGate interface

Use the following command to add an IPv4 VRRP virtual router to the port10 interface of a FortiGate. This VRRP virtual router has a virtual router ID of 200, uses IP address 10.31.101.200 and has a priority of 255. Since this is the highest priority this interface is configured to be the master of the VRRP group with ID number 200.

VRRP can only be configured on physical interfaces or VLAN interfaces. You cannot configure VRRP on hardware-switch interfaces where multiple physical interfaces are combined into a hardware switch interface.

```
config system interface
edit port10
config vrrp
```

```
edit 200
    set vrip 10.31.101.200
    set priority 255
end
end
```

Adding an IPv6 VRRP virtual router to a FortiGate interface

Use the following command to add an IPv6 VRRP virtual router to the port20 interface of a FortiGate. This VRRP virtual router has a virtual router ID of 220, uses IP address 2001:db8:1::12 and has a priority of 255. Since this is the highest priority this interface is configured to be the master of the VRRP group with ID number 220.

```
config system interface
    edit port20
        config ipv6
            config vrrp6
                edit 220
                    set vrip 2001:db8:1::12
                    set priority 255
                end
            end
        end
    end
```

Setting up VRRP failover

VRRP routers in a VRRP group periodically send VRRP advertisement messages to all of the routers in the group to maintain one router as the primary router and the others as backup routers. The primary router is the one with the highest priority. If the backup routers stop receiving these packets from the primary router, the backup router with the highest priority becomes the new primary router.

The primary router stops sending VRRP advertisement messages if it either fails or becomes disconnected. You can also configure VRRP destination addresses that the primary router monitors. If the primary router becomes unable to connect to these destination addresses, it stops sending VRRP advertisement messages and the backup router with the highest priority becomes the primary router. You can add one or two destination addresses to a VRRP configuration. To be most effective, these destination addresses should be remote addresses.

For example, configure IPv4 VRRP on port14 with two destination address:

```
config system interface
    edit port14
        config vrrp
            edit 12
                set vrdst 10.10.10.20 10.20.20.10
            end
        end
    end
```

Configure IPv6 VRRP on port23 with one destination address:

```
config system interface
    edit port23
        config ipv6
            config vrrp6
                edit 223
                    set vrdst 2001:db8:1::12
                end
            end
        end
    end
```

IPv4 VRRP active failover

You can reduce IPv4 VRRP failover times with the `vrdst-priority` option. This option causes the primary router to actively signal to the backup routers when the primary router can't reach its configured destination address or addresses. The primary router does this by sending a lower priority for itself in the VRRP advertisement messages. You set this lower priority with the `vrdst-priority` option. The backup router with the highest priority becomes the new primary router and takes over processing traffic.

The following example configures the primary router to have a priority of 255 so it should always become the primary router. The command also sets `vrdst-priority` to 10. So if the primary router can no longer connect to its destination address of 10.10.10.1, the primary router informs the VRRP group that its priority is now 10.

```
config system interface
  edit port10
    config vrrp
      edit 12
        set vrip 10.31.101.200
        set priority 255
        set vrdst 10.10.10.1
        set vrdst-priority 10
      end
    end
```

Failover of IPv4 firewall VIPs and IP pools

FortiOS VRRP HA supports failover of firewall VIPs and IP Pools when the status of a virtual router (VR) changes. This feature introduces a new proxy ARP setting to map VIP and IP Pool address ranges to each VR's Virtual MAC (VMAC). After failover, the IP Ranges added to the new primary VR are routed to the new primary VR's VMAC.

Use the following command to add a proxy ARP address range and a single IP address to a VR added to a FortiGate's port5 interface. The address range and single IP address should match the address range or single IP for VIPs or IP Pools added to the port5 interface:

```
config system interface
  edit port5
    config vrrp
      edit 1
        config proxy-arp
          edit 1
            set ip 192.168.62.100-192.168.62.200
          next
          edit 2
            set ip 192.168.62.225
          end
        end
      end
    end
```

Changing the advertisement message interval

By default, VRRP advertisement messages are sent once a second. You can use the following to change the frequency of sending these messages. The range is 1 to 255 seconds.

For example, configure an IPv4 VRRP to send advertisement messages every 10 seconds:

```
config system interface
  edit port14
    config vrrp
      edit 12
        set adv-interval 10
      end
    end
```

Configure IPv6 VRRP to send advertisement messages every 20 seconds:

```
config system interface
  edit port23
    config ipv6
      config vrrp6
        edit 223
          set adv-interval 20
        end
      end
    end
```

Changing how long backup routers wait before assuming the primary router has failed

The VRRP startup time is the maximum time that a backup router waits between receiving advertisement messages from the primary router. If the backup router has to wait longer than the start-time, it assumes the primary router has failed and becomes the new primary router.

The default startup time is 3 seconds and the range is 1 to 255 seconds.

In some cases the advertisement messages may be delayed. For example, some switches with spanning tree enabled may delay some of the advertisement message packets. If you find that backup routers are attempting to become primary routers even though the primary router hasn't failed, you can extend the start time to make sure the backup routers wait long enough for the advertisement messages.

For example, set the IPv4 VRRP startup time to 10 seconds:

```
config system interface
  edit port14
    config vrrp
      edit 12
        set start-time 10
      end
    end
```

Configure set the IPv6 VRRP startup time to 15 seconds:

```
config system interface
  edit port23
    config ipv6
      config vrrp6
        edit 223
          set start-time 15
        end
      end
    end
```

Using VRRP virtual MAC addresses

The VRRP virtual MAC address (or virtual router MAC address) is a shared MAC address adopted by the primary router. If the primary router fails, the same virtual MAC address is picked up by the new primary router allowing all devices on the network to transparently connect to the default route using the same virtual MAC address. You must enable the VRRP virtual MAC address feature on all members of a VRRP group.

Each VRRP router is associated with its own virtual MAC address. The last part of the virtual MAC depends on the VRRP virtual router ID using the following format:

```
00-00-5E-00-01-<VRID_hex>
```

Where <VRID_hex> is the VRRP virtual router ID in hexadecimal format in internet standard bit-order. For more information about the format of the virtual MAC see [RFC 3768](#).

Some examples:

- If the VRRP virtual router ID is 10 the virtual MAC would be 00-00-5E-00-01-0a.
- If the VRRP virtual router ID is 200 the virtual MAC would be 00-00-5E-00-01-c8.

The VRRP virtual MAC address feature is disabled by default. When you enable the feature on a FortiGate interface, all of the VRRP routers added to that interface use their own VRRP virtual MAC address. Each virtual MAC address will be different because each virtual router has its own ID.

Use the following command to enable the VRRP virtual MAC address for an IPv4 VRRP configuration on the port2 interface:

```
config system interface
  edit port2
    set vrrp-virtual-mac enable
  end
end
```

The port2 interface will now accept packets sent to the MAC addresses of the IPv4 VRRP virtual routers added to this interface.

Use the following command to enable the VRRP virtual MAC address for an IPv6 VRRP configuration on the port22 interface:

```
config system interface
  edit port22
    config ipv6
      set vrrp-virtual-mac6 enable
    end
  end
end
```

The port22 interface now accepts packets sent to the MAC addresses of the IPv6 VRRP virtual routers added to this interface.

Since devices on the LAN do not have to learn a new MAC address for a new VRRP router in the event of a failover, this feature can improve network efficiency, especially on large and complex networks.

If the VRRP virtual MAC address feature is disabled, the VRRP group uses the MAC address of the master. In the case of a FortiGate VRRP virtual router this is the MAC address of the FortiGate interface that the VRRP virtual routers are added to. If a master fails, when the new master takes over it sends gratuitous ARPs to associate the VRRP virtual router IP address with the MAC address of the new master (or the interface of the FortiGate that has become the new master). If the VRRP virtual MAC address is enabled the new master uses the same MAC address as the old master.

Setting up VRRP groups

A VRRP group includes all the relevant VRRP IDs and tracks the VRRP status to force the status of all group members if a VRRP domain is changed from primary to backup. The VRRP group ID can be between 1 and 65535.

For an IPv4 VRRP configuration, use the following command to add a VRRP group to the port20 interface that includes the virtual route identifiers 25, 50, 66 and 70 to VRRP group 10.

```
config system interface
  edit port20
    config vrrp
      edit 25
```

```
        set vrgrp 10
    next
    edit 50
        set vrgrp 10
    next
    edit 66
        set vrgrp 10
    next
    edit 70
        set vrgrp 10
    end
```

For an IPv6 VRRP configuration, use the following command to add a VRRP group to the port22 interface that includes the virtual route identifiers 10, 51, and 83 to VRRP group 60.

```
config system interface
    edit port22
        config ipv6
            config vrrp6
                edit 10
                    set vrgrp 60
                next
                edit 51
                    set vrgrp 60
                next
                edit 83
                    set vrgrp 60
            end
```

Example IPv4 VRRP configuration: two FortiGates in a VRRP group

This example includes a VRRP group consisting of two FortiGates that connect an internal network to the internet. As shown below, the internal network's default route is 10.31.101.120.

The FortiGate port2 interfaces connect to the internal network. A VRRP virtual router is added to each FortiGate's port2 interface. The virtual router IP address is 10.31.101.120 (the internal network's default route) and the virtual router's ID is 5. The VRRP priority of the primary router is set to 255 and the VRRP priority of the backup router is 50. The port2 interface of each FortiGate should have an IP address that is different from the virtual router IP address and the port2 interface IP addresses should be different from each other.

This example also includes enabling the VRRP virtual MAC address on both FortiGate port2 interfaces so that the VRRP group uses the VRRP virtual MAC address.

Example VRRP configuration with two FortiGates

To configure the FortiGates for VRRP

1. Select one of the FortiGates to be the primary VRRP router and the other to be the backup router.
2. From the primary router CLI, enter the following command to enable the VRRP virtual MAC address on the port2 interface and add the VRRP virtual router to the port2 interface:

```
config system interface
  edit port2
    set vrrp-virtual-mac enable
    config vrrp
      edit 5
        set vrip 10.31.101.120
        set priority 255
      end
    end
  end
```

3. From the backup router CLI, enter the following command to enable the VRRP virtual MAC address on the port2 interface and add the VRRP virtual router to the port2 interface:

```
config system interface
  edit port2
    set vrrp-virtual-mac enable
    config vrrp
      edit 5
        set vrip 10.31.101.120
        set priority 50
      end
    end
  end
```

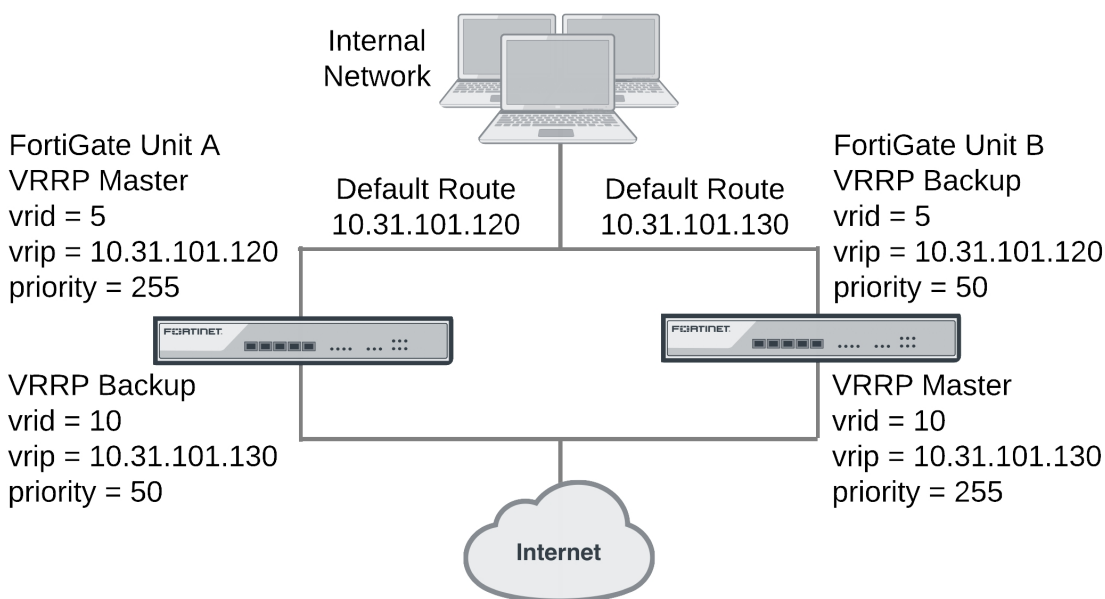

Example IPv4 VRRP configuration: VRRP load balancing two FortiGates and two VRRP groups

In this configuration two VRRP groups are involved. Each FortiGate participates in both of them. One FortiGate is the primary router of one group and the other FortiGate is the primary router of the other group. The network distributes traffic between two different default routes (10.31.101.120 and 10.31.101.130). One VRRP group is configured with one of the default route IP addresses and the other VRRP group gets the other default route IP address. During normal operation, both FortiGates are processing traffic and the VRRP groups are used to load balance the traffic between the two FortiGates.

If one of the FortiGates fails, the remaining FortiGate becomes the primary router of both VRRP groups. The network sends all traffic for both default routes to this FortiGate. The result is a configuration that, under normal operation load, balances traffic between two FortiGates, but if one of the FortiGates fails, all traffic fails over to the FortiGate that is still operating.

This example also includes enabling the VRRP virtual MAC address on both FortiGate port2 interfaces so that the VRRP groups use their VRRP virtual MAC addresses.

Example VRRP configuration with two FortiGates and two VRRP groups

To configure the FortiGates

1. Log into the CLI of FortiGate A.
2. Enter the following to enable the VRRP virtual MAC address feature and add the VRRP groups to the port2 interface of FortiGate A:

```
config system interface
edit port2
set vrrp-virtual-mac enable
config vrrp
```

```
edit 50 (32)
    set vrip 10.31.101.120
    set priority 255
next
edit 100 (64)
    set vrip 10.31.101.130
    set priority 50
end
end
```

3. Log into the CLI of FortiGate B.

4. Enter the following command to enable the VRRP virtual MAC address feature and add the VRRP groups to the port2 interface of FortiGate B:

```
config system interface
edit port2
    set vrrp-virtual-mac enable
config vrrp
edit 50
    set vrip 10.31.101.120
    set priority 50
next
edit 100
    set vrip 10.31.101.130
    set priority 255
end
end
```

Optional VRRP configuration settings

In addition to the basic configuration settings, you can change to the VRRP configuration in the following ways. All of these options apply to both IPv4 and IPv6 VRRP unless noted.

- Enable or disable individual virtual router configurations using the `status` option. Normally virtual router configurations are enabled but you can temporarily disable one if it is not required.
- Enable or disable preempt mode using the `preempt` option. In preempt mode, a higher priority backup router can preempt a lower priority primary router. This can happen if the primary router has failed, a backup router has become the primary router, and the failed primary router restarts. Since the restarted router has a higher priority, if preempt mode is enabled the restarted router replaces the current primary router becoming the new primary router. Preempt mode is enabled by default.
- You can add one or two destination addresses (`vrdst`) to a VRRP configuration. To be most effective, these destination addresses should be remote addresses.

FortiController-5000 SLBC support

FortiController-5000 Session Aware Load Balancing Clustering (SLBC) supports the Virtual Router Redundancy Protocol (VRRP), allowing you to configure HA between FortiController-5000 SLBC clusters using VRRP. You can also add a FortiController-5000 SLBC cluster to a VRRP group with other VRRP routers.

You configure VRRP on the FortiController-5000 by creating a VRRP group and adding one or more FortiController front panel interfaces to the group. During normal operation, the primary FortiController sends outgoing VRRP routing advertisements. Both the primary and backup FortiControllers listen for incoming VRRP advertisements from other routers in the VRRP group. If the primary FortiController fails, the new primary

FortiController takes over the role of both sending and receiving VRRP advertisements, maintaining the FortiController-5000 cluster within the VRRP group.

FortiGate Session Life Support Protocol (FGSP)

In a network that already includes load balancing (either with load balancers or routers) for traffic redundancy, two or more FortiGates can be integrated into the load balancing configuration using the FortiGate Session Life Support Protocol (FGSP). The external load balancers or routers can distribute sessions among the FortiGates and the FGSP performs session synchronization of IPv4 and IPv6 TCP, SCTP, UDP, ICMP, expectation, and NAT sessions and IPsec tunnels to keep the session tables of the FortiGates synchronized. If one of the FortiGates fails, session failover occurs and active sessions fail over to the FortiGates that are still operating. This failover occurs without any loss of data. As well, the external routers or load balancers will detect the failover and re-distribute all sessions to the peers that are still operating.

The FortiGates operate as peers that process traffic and synchronize sessions with other FortiGates in the cluster. An FGSP cluster can include from 2 to 16 FortiGates. Adding more FortiGates increases the CPU and memory required to keep all of the FortiGates synchronized. So depending on your network conditions, adding too many FortiGates to an FGSP cluster may reduce overall performance.

The FortiGates in the FGSP cluster must be the same model and be running the same firmware version. You use the `config system cluster-sync` command to configure FGSP between the FortiGates and the `config system ha` command to configure what is synchronized.

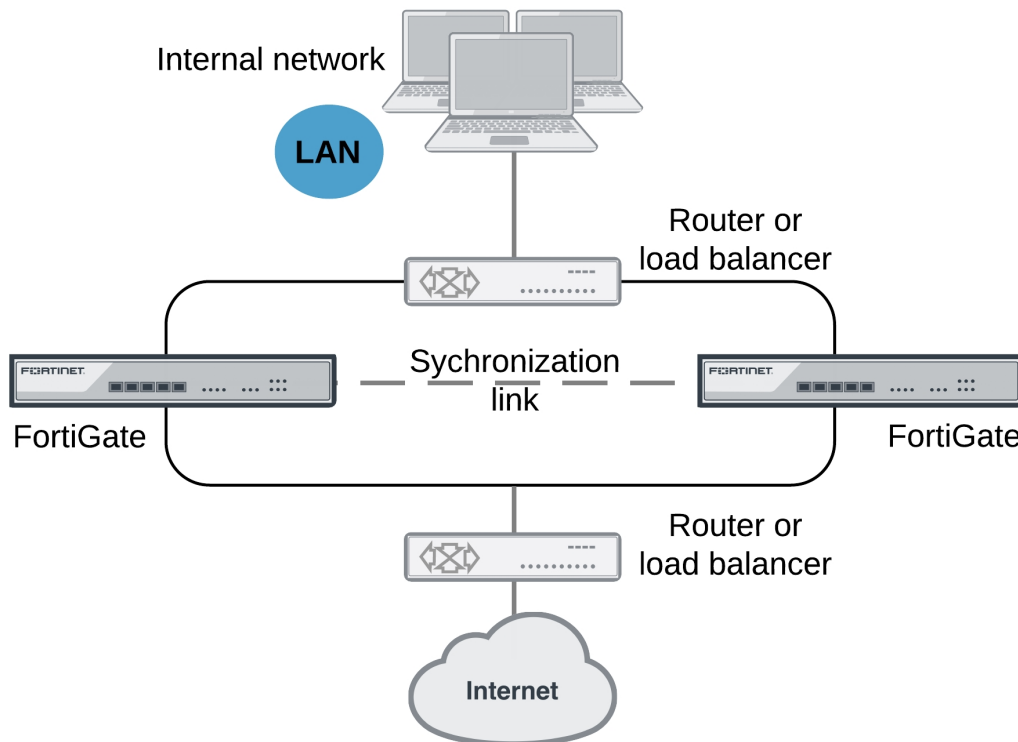

In previous versions of FortiOS the FGSP was called TCP session synchronization or standalone session synchronization. The FGSP has been expanded to include configuration synchronization and session synchronization of connectionless sessions, expectation sessions, and NAT sessions and IPsec tunnels.

FGSP also supports synchronizing sessions between FGCP clusters and between FGCP clusters and standalone FortiGates. See [Session synchronization between FGCP clusters on page 1608](#). FGSP is also compatible with FortiGate VRRP.

The FGSP can be used instead of FGCP HA to provide **session synchronization** between two peer FortiGates. If the external load balancers direct all sessions to one peer the affect is similar to active-passive FGCP HA. If external load balancers or routers load balance traffic to both peers, the effect is similar to active-active FGCP HA. The load balancers should be configured so that all of the packets for any given session are processed by the same peer. This includes return packets.

FGSP HA

By default, FGSP synchronizes all IPv4 and IPv6 TCP sessions, IPsec tunnels, and also synchronizes the configuration of the FortiGates.

You can optionally enable session pickup to synchronize connectionless (UDP and ICMP) sessions, expectation sessions, and NAT sessions. If you do not enable session pickup, the FGSP does not share session tables for the particular session type and sessions do not resume after a failover. All sessions are interrupted by the failover and must be re-established at the application level. Many protocols can successfully restart sessions with little, or no, loss of data. Others may not recover easily. Enable session pickup for sessions that may be difficult to reestablish. Since session pickup requires FortiGate memory and CPU resources, only enable this feature for sessions that you need to have synchronized.

The synchronization link is set up in the same way as FGCP heartbeat interfaces. You must connect the synchronization link interfaces together and use the heartbeat device (hbdev) option to add the heartbeat devices to the configuration.

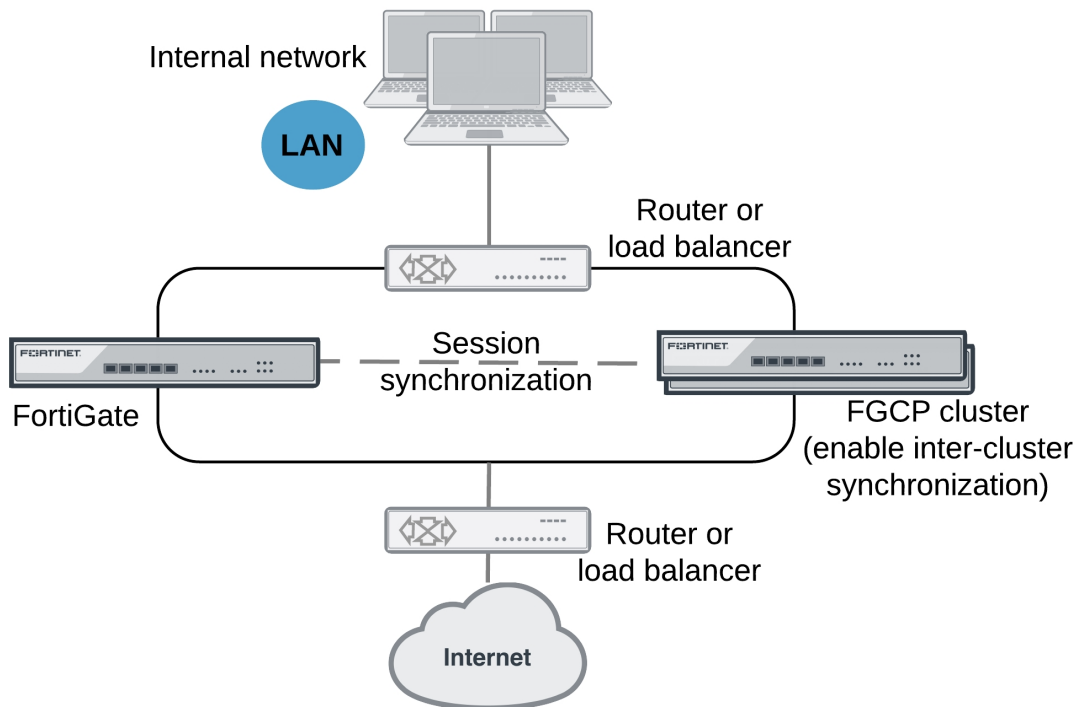

You can also optionally add filters to control which sessions are synchronized. You can add filters to only synchronize packets from specified source and destination addresses, specified source and destination interfaces, and specified services.

Load balancing and session failover is done by external routers or load balancers instead of by the FGSP. The FortiGates only perform session synchronization to support session failover as well as configuration synchronization.

Session synchronization between FGCP clusters

Session synchronization between FGCP clusters (also called inter-cluster session synchronization) allows you to synchronize sessions among FGCP clusters and standalone FortiGates. The FGSP can synchronize sessions among up to four FGCP clusters and FortiGates.

Example session synchronization between a FortiGate and an FGCP cluster

Enter the following command to enable inter-cluster synchronization on an FGCP cluster:

```
config system ha
  set inter-cluster-session-sync enable
end
```

Once you enable inter-cluster session synchronization, all FGSP configuration options are available in the FGCP cluster CLI and you can set up the FGSP configuration in the same way as for standalone FortiGates.

Inter-cluster session synchronization is compatible with all FGCP operating modes, such as active-active, active-passive, virtual clustering, full mesh HA.

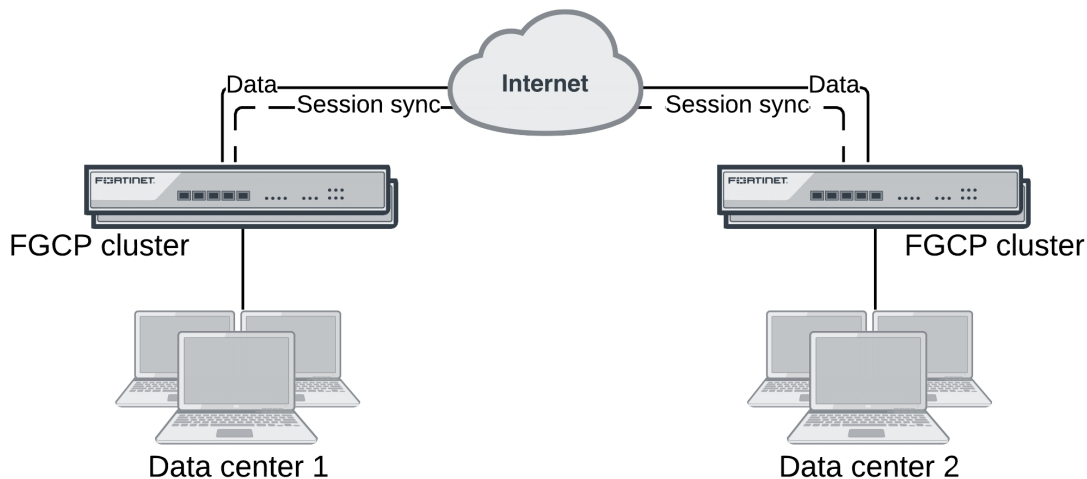

What is synchronized?

Inter-cluster session synchronization synchronizes all supported FGSP session types, including TCP sessions, IPsec tunnels, IKE routes, connectionless sessions (UDP and ICMP), NAT sessions, asymmetric sessions, and expectation sessions. Inter-cluster session synchronization doesn't support configuration synchronization.

Inter-cluster synchronization between data centers

Inter-cluster session synchronization is deployed for session-synchronization among multiple data centers if one or more of the data centers is protected by an FGCP cluster.

Example inter-cluster session synchronization between two data centers

In this example, you enable inter-cluster session synchronization for both of the clusters, and then configure session synchronization options on each cluster, as required.

Configuring FGSP HA cluster-sync instances

You use the following command to configure an FGSP HA cluster-sync instance.

```
config system cluster-sync
  edit 1
    set peerip <peer-ip-address>
    set peervd <vdom-name>
    set syncvd <vdom-name>
  end
```

Where:

- `peerip` is the IP address of an interface of another FortiGate in the FGSP cluster that this configuration synchronizes sessions to.
- `peervd` is the name of the VDOM on the other FortiGate that should be synchronized with this one. By default the `peervd` is `root`.
- `syncvd` is the name of the VDOM of the FortiGate that should be synchronized with the other FortiGate. If multiple VDOMs are not enabled, `syncvd` should be set to `root`.

For FGSP HA to work properly, all VDOMs to be synchronized must be added to all of the FortiGates in cluster. The names of the matching interfaces in each VDOM must also be the same; this includes the names of matching VLAN interfaces. Note that the index numbers of the matching interfaces and VLAN interfaces can be different. Also the VLAN IDs of the matching VLAN interfaces can be different. If you enable configuration synchronization this will happen automatically.

This command creates a cluster-sync instance that causes a FortiGate to synchronize the TCP sessions of one of its VDOMs (by default the root VDOM) to the root VDOM of another FortiGate (which would become another FortiGate in the FGSP cluster). You can also use the `config system ha` command to synchronize more session types and to synchronize the configuration. Cluster-sync instances are not synchronized and must be added to each FortiGate in the cluster.

A cluster of two FortiGates would only require one `cluster-sync` instance for each VDOM to be synchronized. This instance would synchronize the sessions from the root VDOM of one FortiGate to the root VDOM of the other. The second FortiGate would also include a cluster-sync instance to synchronize its root VDOM with the root VDOM of the other FortiGate.

In a multiple VDOM configuration, you add a separate cluster-sync instance for each VDOM to be synchronized. You don't have to synchronize all VDOMs. If multiple VDOMs are enabled, the `config system cluster-sync` command is a global command.

FGSP clusters with three or more FortiGates

If an FGSP cluster includes three or more FortiGates you must explicitly define all of the cluster-sync instances that you need. In a cluster of four FortiGates, each FortiGate can be synchronized with up to three other FortiGates. So, to synchronize all of the FortiGates, you must add three cluster-sync instances to each FortiGate (or $n-1$, where n is the number of FortiGates in the cluster).

Selecting the sessions to synchronize

You can add a cluster-sync instance with a filter to only synchronize some sessions. A filter can be added to a cluster-sync instance as follows:

```
config system cluster-sync
  edit 1
    set peerip <peer-ip-address>
    set peervd <vdom-name>
    set syncvd <vdom-name>
    config session-sync-filter
      srcintf <interface-name>
      dstintf <interface-name>
      srcaddr x.x.x.x x.x.x.x
      dstaddr x.x.x.x x.x.x.x
      srcaddr6 ::/x
      dstaddr6 ::/x
    end
  end
```

You can use the filter to only synchronize sessions according to the session source and destination interface and IPv4 or IPv6 address.

You can only add one filter to a cluster-sync instance. To create multiple filters you must create multiple cluster-sync instances.

Synchronizing TCP and SCTP sessions

Use the following to enable session synchronization for TCP and SCTP sessions and to configure the FGSP to use the port8 interface for synchronizing traffic:

```
config system ha
    set session-pickup enable
    set hbdev "port8" 50
end
```

Automatic session sync after peer reboot

You can configure your FGSP cluster to resume sessions more smoothly after a failed FortiGate rejoins the cluster. In some cases when a failed FortiGate in the cluster comes back up it may begin processing sessions before the session table from the other FortiGate in the cluster has been synchronized to it. When this happens, the FortiGate may drop packets until the session synchronization is complete.

Shutting down interfaces during session synchronization

This feature allows you to shut down some interfaces on the failed FortiGate when it is starting up so that it will not accept packets until session synchronization is complete. Then the interfaces are brought up and traffic can flow. While the interfaces are down, the FortiGate that had not failed keeps processing traffic.

Use the following to select the interfaces to shutdown while waiting for session synchronization to complete:

```
config system cluster-sync
    edit 1
        set down-intfs-before-sess-sync port1 port2
    end
```

Heartbeat monitoring

If the FortiGate that was running fails before session synchronization is complete, the FortiGate that is restarting will not be able to complete session synchronization and will not turn on its shutdown interfaces. To prevent this from happening, FGSP includes heartbeat monitoring. Using heartbeat monitoring, the FortiGate that is waiting for session synchronization to finish can detect that the other FortiGate is down and turn on its interfaces even if session synchronization is not complete. You can use the following to change the heartbeat interval (`hb-interval`) and lost heartbeat threshold (`hb-lost-threshold`) to change heartbeat monitoring timing.

```
config system cluster-sync
    edit 1
        set hb-interval 2
        set hb-lost-threshold 3
    end
```

Synchronizing the configuration

The FGSP includes configuration synchronization, allowing you to make configuration changes once for all of the FortiGates in the cluster, instead of requiring you to make redundant configuration changes on each FortiGate.

By default, configuration synchronization is disabled. You can enter the following to enable it:

```
config system ha
    set standalone-config-sync enable
end
```

You must enter this command on all of the FortiGates in the FGSP cluster. When you enable synchronizing the configuration, the FGSP uses FGCP primary unit selection to select a config sync primary (or master) FortiGate. The other FortiGates in the FGSP cluster become config sync backup FortiGates. The FGSP synchronizes all configuration changes that you make on the config sync primary FortiGate to the config sync backup FortiGates. Fortinet recommends making all configuration changes on the config sync primary FortiGate.

Config sync primary FortiGate selection

The FGSP cluster uses FGCP primary unit selection to select the FGSP config sync primary FortiGate (see [Primary unit selection on page 1385](#)). So normally, the FortiGate with the highest serial number would become the primary FortiGate.

You can use device priority select one of the FortiGates to become the config sync primary FortiGate. For example, the following command enables configuration synchronization on a FortiGate and sets a higher device priority than the default of 128 to make sure that this FortiGate becomes the primary FortiGate.

```
config system ha
    set standalone-config-sync enable
    set priority 250
end
```

Settings that are not synchronized

FGSP configuration synchronization does not synchronize settings that identify the FortiGate to the network. The following settings are not synchronized:

- Transparent mode management IPv4 and IPv6 IP addresses and default gateways.
- All `config system cluster-sync` settings.
- All `config system interface` settings except `vdom`, `vlanid`, `type` and `interface`.
- All `config firewall sniffer` settings.
- All router BFD and BFD6 settings.
- The following BGP settings: `as`, `router-id`, `aggregate-address`, `aggregate-address6`, `neighbor-group`, `neighbor`, `network`, and `network6`.
- The following OSPF settings: `router-id`, `area`, `ospf-interface`, `network`, `neighbor`, and `summary-address`.
- The following OSPF6 settings: `router-id`, `area`, and `ospf6-interface`.
- All RIP settings.
- All policy routing settings.
- All static routing settings.

FGSP and firmware upgrades

The steps to follow to upgrade the firmware running on an FGSP cluster depend on whether you have enabled configuration synchronization (see [Synchronizing the configuration on page 1611](#)) or not:

- If you have not enabled configuration synchronization, you must upgrade the firmware separately on each FortiGate in the cluster. Upgrading the firmware of each FortiGate interrupts traffic through that FortiGate.
- If you have enabled configuration synchronization, you can upgrade the cluster firmware by upgrading the firmware running on the sync primary FortiGate. The FGSP then sends the new firmware image to the config sync backup FortiGates and all of the FortiGates in cluster install the new firmware and restart. The firmware upgrade simultaneously interrupts traffic through all of the FortiGates in the cluster.

Backing up and restoring the configuration of an FGSP cluster

You should maintain separate backup configuration files for each FortiGate in the FGSP cluster. When you restore the configuration of one of the FortiGates in an FGSP cluster, the FGSP does not synchronize the configuration file to the other FortiGates in the FGSP cluster. Instead you must back up each FortiGate separately and restore the configuration of each FortiGate separately with its own configuration file.

IPsec tunnel synchronization

When you use the `config system cluster-sync` command to enable FGSP, IPsec keys and other runtime data (but not actual tunnel sessions) are synchronized between cluster units. This means that if one of the cluster units goes down, the cluster units that are still operating can quickly get IPsec tunnels re-established without re-negotiating them. However, after a failover, all existing tunnel sessions on the failed FortiGate have to be restarted on the FortiGates that are still operating.

IPsec tunnel sync supports both static and dialup IPsec tunnels. For IPsec tunnel synchronization to work, the interfaces on the FortiGates that are tunnel endpoints must have the same IP addresses and external routers must be configured to load balance IPsec tunnel sessions to the FortiGates in the cluster.

Optionally synchronizing IKE routes

You can use the following command to control whether IKE routes are synchronized to all units in the FGSP cluster.

```
config system cluster-sync
  edit 0
    set slave-add-ike-routes {enable | disable}
  end
```

Enable to synchronize IKE routes, disable if you do not need to synchronize IKE routes. Enabling routing synchronization is optional but doing so increases synchronization overhead and bandwidth usage. If you have problems with IPsec VPN tunnel synchronization, you may want to enable synchronizing routes. Otherwise you could leave it disabled to improve performance and save bandwidth.

Synchronizing UDP and ICMP (connectionless) sessions

In many configurations, due to their non-stateful nature, UDP and ICMP sessions don't need to be synchronized to naturally failover. However, if required you can configure the FGSP to synchronize UDP and ICMP sessions by entering the following:

```
config system ha
  set session-pickup enable
  set session-pickup-connectionless enable
end
```

Synchronizing NAT sessions

By default, NAT sessions are not synchronized. However, the FGSP can synchronize NAT sessions if you enter the following:

```
config system ha
  set session-pickup enable
```

```
set session-pickup-nat enable
end
```

However, if you want NAT sessions to resume after a failover, you should not configure NAT to use the destination interface IP address since the FGSP FortiGates have different IP addresses. With this configuration, after a failover all sessions that include the IP addresses of interfaces on the failed FortiGate will have nowhere to go since the IP addresses of the failed FortiGate will no longer be on the network.

Instead, in an FGSP configuration, if you want NAT sessions to failover, you should use IP pools with the type set to overload (which is the default IP pool type). For example:

```
config firewall ippool
edit FGSP-pool
set type overload
set startip 172.20.120.10
set endip 172.20.120.20
end
```

Then when you configure NAT firewall policies, turn on NAT and select to use dynamic IP pool and select the IP pool that you added. Configuration synchronization should add the same IP pools and firewall policies to all FortiGates in the cluster. If configuration synchronization is not enabled you must add the same IP pools and policies to all of the FortiGates in the cluster.

Synchronizing asymmetric sessions

By default, asymmetric sessions are not synchronized. Normally, session synchronization cannot be asymmetric because it is stateful. So all of the packets of a given session must be processed on the same FortiGate. This includes return packets.

However, if you have an asymmetric routing configuration, you can enter the following command to synchronize asymmetric sessions by dynamically detecting asymmetric sessions and disabling anti-reply for these sessions.

```
config system ha
set session-pickup enable
set session-pickup-expectation enable
end
```

The FGSP enforces firewall policies for asymmetric traffic, including cases where the TCP 3-way handshake is split between two FortiGates. For example, FGT-A receives the TCP-SYN, FGT-B receives the TCP-SYN-ACK, and FGT-A receives the TCP-ACK. Under normal conditions, a firewall will drop this connection since the 3-way handshake was not seen by the same firewall. However, two FortiGates with FGSP configured will be able to properly pass this traffic since the firewall sessions are synchronized.

This asymmetric function can also work with connectionless UDP and ICMP traffic. If traffic will be highly asymmetric, as described above, the following command must be enabled on both FortiGates.

```
config system ha
set session-pickup enable
set session-pickup-connectionless enable
end
```

Synchronizing asymmetric traffic can be very useful in situations where multiple internet connections from different ISPs are spread across multiple FortiGates. Since it is typically not possible to guarantee internet-bound traffic leaving via an ISP will return using the exact same ISP, the FGSP provides critical firewall functions in this situation.

Asymmetric sessions may not be synchronized in low latency networks if the reply packet is received before the peer has received the session synchronization packet. This limitation usually only occurs in low latency networks.

The FGSP also has applications in virtualized computing environments where virtualized hosts move between data centers. The firewall session synchronization features of FGSP allow for more flexibility than in traditional firewalling functions.

Synchronizing expectation sessions

FortiOS session helpers keep track of the communication of Layer-7 protocols such as FTP and SIP that have control sessions and expectation sessions. Usually the control sessions establish the link between server and client and negotiate the ports and protocols that will be used for data communications. The session helpers then create expectation sessions through the FortiGate for the ports and protocols negotiated by the control session.

The expectation sessions are usually the sessions that actually communicate data. For FTP, the expectation sessions transmit files being uploaded or downloaded. For SIP, the expectation sessions transmit voice and video data. Expectation sessions usually have a timeout value of 30 seconds. If the communication from the server is not initiated within 30 seconds, the expectation session times out and traffic will be denied.

By default the FGSP does not synchronize expectation sessions and if a failover occurs, the sessions will have to be restarted.

If you want to synchronize expectation sessions so that they will continue after a failover, you can enter the following:

```
config system ha
    set session-pickup enable
    set session-pickup-expectation enable
end
```

GTP session synchronization: FGSP for FortiOS Carrier

FortiOS Carrier FGSP supports GTP session synchronization, allowing you to synchronize GTP sessions among up to four FortiGates or clusters running FortiOS Carrier. No special configuration is required to support GTP session synchronization. GTP sessions are synchronized like any other TCP or UDP session.

One limitation to this configuration is that asymmetric routing is not supported. So the router or load balancer that load balances the GTP sessions must send all of the packets of a session to the same FortiGate.

Also, for GTP sessions to be synchronized, session synchronization must be enabled. Also, since most GTP traffic uses UDP you should also enable UDP session synchronization. For example:

```
config system ha
    set session-pickup enable
    set session-pickup-connectionless enable
end
```

Security profile flow-based inspection and asymmetric traffic

Security profile inspection (flow- or proxy-based) for a session is not expected to work properly if the traffic in the session is balanced across more than one FortiGate in either direction. Flow-based inspection should be used in FGSP deployments.

For an environment where traffic is symmetric, security profile inspection can be used with the following limitations:

- No session synchronization for the sessions inspected using proxy-based inspection. Sessions will drop and need to be reestablished after data path failover.

- Sessions with flow-based inspection will failover; however, inspection of failed over sessions after the failover may not work.

A single FortiGate must see both the request and reply traffic for security profile inspection to function correctly. For environments where asymmetric traffic is expected, security profile inspection should not be used.

Notes and limitations

FGSP HA has the following limitations:

- The FGSP is a global configuration option. As a result you can only add one service to a filter configuration. You cannot add custom services or service groups even if virtual domains are not enabled.
- You can only add one filter configuration to a given FGSP configuration. However, you can add multiple filters by adding multiple identical FGSP configurations, each one with a different filter configuration.
- Sessions accepted by security policies with security profiles configured are not synchronized.
- FGSP HA is configured from the CLI.
- FGSP HA is available for FortiGates or virtual domains operating in NAT or transparent mode. NAT sessions are not synchronized in either mode (unless NAT synchronization is enabled as described in [Synchronizing NAT sessions on page 1613](#)). In NAT/Route mode, only sessions for route mode security policies are synchronized. In transparent mode, only sessions for normal transparent mode policies are synchronized.
- FGSP HA is supported for traffic on physical interfaces, VLAN interfaces, zones, aggregate interfaces, and NPx (NP4, NP6 etc.) accelerated interfaces. The FGSP has not been tested for inter-ldom links, between HA clusters, and for redundant interfaces.
- The names of the matching interfaces, including VLAN interfaces, aggregate interfaces and so on, must be the same on both peers.
- An FGSP cluster can include from 2 to 16 FortiGates. Adding more FortiGates increases the CPU and memory required to keep all of the FortiGates synchronized.

Configuring session synchronization links

When FGSP HA is operating, the FortiGates share session information over Ethernet links similar to an HA heartbeat link. Usually you would use the same interface on each FortiGate for session synchronization. If possible you should connect the session synchronization interfaces directly without using a switch or other networking equipment. For FortiGate-5000 systems you can use a backplane interface as the session synchronization link.

You can use different interfaces on each FortiGate for session synchronization links. Also, if you have multiple session synchronization configurations, you can have multiple links between the FortiGates. In fact if you are synchronizing a lot of sessions, you may want to configure and connect multiple session synchronization links to distribute session synchronization traffic to these multiple links.

You cannot configure backup session synchronization links. Each configuration only includes one session synchronization link.

The session synchronization link should always be maintained. If session synchronization communication is interrupted and a failure occurs, sessions will not failover and data could be lost.

Session synchronization traffic can use a considerable amount of network bandwidth. If possible, session synchronization link interfaces should only be used for session synchronization traffic and not for data traffic.

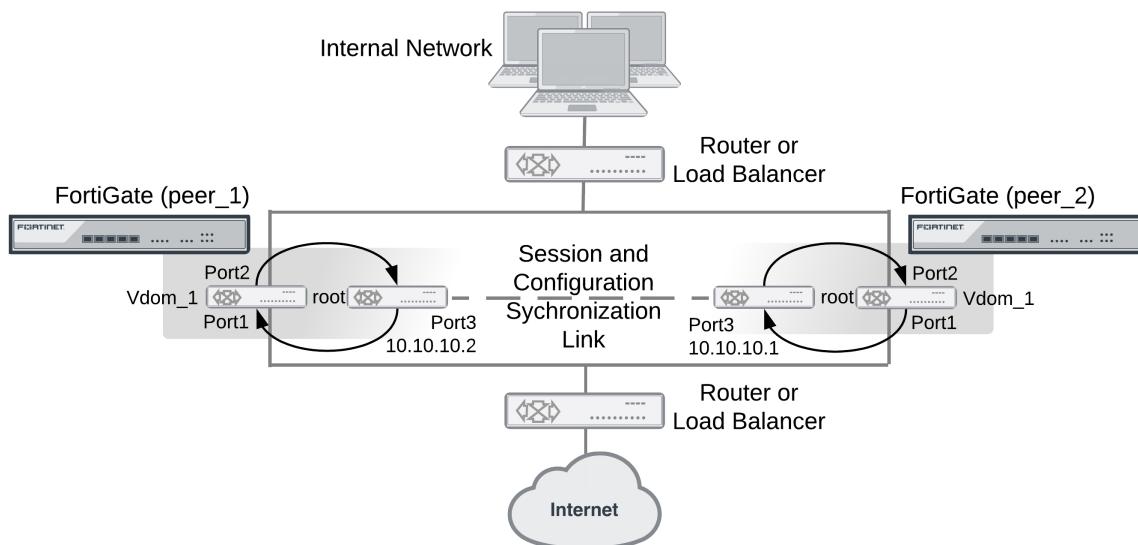

Basic example configuration

The following configuration example shows how to configure basic FGSP HA for the two peer FortiGates shown below.

- The host names of peers are peer_1 and peer_2.
- Both peers are configured with two virtual domains: root and vdom_1.
- All sessions processed by vdom_1 are synchronized.
- The synchronization link interface is port3 which is in the root virtual domain.
- The IP address of port3 on peer_1 is 10.10.10.1.
- The IP address of port3 on peer_2 is 10.10.10.2.

Also on both peers, port1 and port2 are added to vdom_1. On peer_1 the IP address of port1 is set to 192.168.20.1 and the IP address of port2 is set to 172.110.20.1. On peer_2 the IP address of port1 is set to 192.168.20.2 and the IP address of port2 is set to 172.110.20.2.

Example FGSP HA network configuration

To configure FGSP HA

1. Configure the load balancer or router to send all sessions to peer_1.
2. Configure the load balancer or router to send all traffic to peer_2 if peer_1 fails.
3. Use normal FortiGate configuration steps on peer_1:
 - Enable virtual domain configuration.
 - Add the vdom_1 virtual domain.
 - Add port1 and port2 to the vdom_1 virtual domain and configure these interfaces.
 - Set the IP address of port1 to 192.168.20.1.
 - Set the IP address of port2 to 172.110.20.1.

- Set the IP address of port3 to 10.10.10.1.
- Add route mode security policies between port1 and port2 to vdom_1.

4. Enter the following commands to configure session synchronization for peer_1:

```
config system cluster-sync
edit 1
set peerip 10.10.10.2
set peervd root
set syncvd vdom_1
end
```

5. Use normal FortiGate configuration steps on peer_2:

- Enable virtual domain configuration.
- Add the vdom_1 virtual domain.
- Add port1 and port2 to the vdom_1 virtual domain and configure these interfaces.
- Set the IP address of port1 to 192.168.20.2.
- Set the IP address of port2 to 172.110.20.2.
- Set the IP address of port3 to 10.10.10.1.
- Add route mode security policies between port1 and port2 to vdom_1.

6. Enter the following command to configure session synchronization for peer_1

```
config system cluster-sync
edit 1
set peerip 10.10.10.1
set peervd root
set syncvd vdom_1
end
```

Now that the FortiGates are connected and configured their configurations are synchronized, so when you make a configuration change on one FortiGate it is synchronized to the other one.

To add filters

You can add a filter to this basic configuration if you only want to synchronize some TCP sessions. For example you can enter the following command to add a filter so that only HTTP sessions are synchronized:

```
config system cluster-sync
edit 1
config filter
set service HTTP
end
end
```

You can also add a filter to control the source and destination addresses of the IPv4 packets that are synchronized. For example, you can enter the following to add a filter so that only sessions with source addresses in the range 10.10.10.100 to 10.10.10.200 are synchronized.

```
config system cluster-sync
edit 1
config filter
set srcaddr 10.10.10.100 10.10.10.200
end
end
```

You can also add a filter to control the source and destination addresses of the IPv6 packets that are synchronized. For example, you can enter the following to add a filter so that only sessions with destination addresses in the range 2001:db8:0:2::/64 are synchronized.

```
config system cluster-sync
  edit 1
    config filter
      set dstaddr6 2001:db8:0:2::/64
    end
  end
end
```

To synchronize TCP sessions

You enter the following to synchronization TCP sessions and set the synchronization link (heartbeat device):

```
config system ha
  set hbdev "port3" 50
  set session-pickup enable
end
```

To synchronize UDP and ICMP sessions

You enter the following to add synchronization of UDP and ICMP sessions to this configuration:

```
config system ha
  set session-pickup enable
  set session-pickup-connectionless enable
end
```

To synchronize the configuration

Enter the following to enable configuration synchronization.

```
config system ha
  set standalone-config-sync enable
end
```

Verifying the FGSP configuration and synchronization

You can use the following diagnose commands to verify that the FGSP and its synchronization functions are operating correctly.

FGSP configuration summary and status

Enter the following command to display a summary of the FGSP configuration and synchronization status:

```
diagnose sys session sync
sync_ctx: sync_started=1, sync_tcp=1, sync_others=1,
sync_expectation=1, sync_redir=0, sync_nat=1, stdalone_sessync=0.
sync: create=12:0, update=0, delete=0:0, query=14
recv: create=14:0, update=0, delete=0:0, query=12
ses pkts: send=0, alloc_fail=0, recv=0, recv_err=0 sz_err=0
nCfG_sess_sync_num=5, mtu=16000
sync_filter:
1: vd=0, szone=0, dzone=0, saddr=0.0.0.0:0.0.0.0, daddr=0.0.0.0:0.0.0.0,
```

`sync_started=1` shows that synchronization is working. If this is set to 0 then something is not correct with session synchronization and synchronization has not been able to start because of it.

`sync_tcp=1, sync_others=1, sync_expectation=1, and sync_nat=1` show that the FGSP has been configured to synchronize TCP, connectionless, asymmetric, and NAT sessions.

`sync: create=12:0 and recv: create=14:0` show that this FortiGate has synchronized 12 sessions to its peer and has received 14 sessions from its peer.

`sync_filter` shows the configured FGSP filter. In this case no filter has been created so all sessions are synchronized.

`vd=0` indicates that root VDOM sessions are synchronized.

Verifying that sessions are synchronized

Enter the command `diagnose sys session list` to display information about the sessions being processed by the FortiGate. In the command output look for sessions that should be synchronized and make sure they contain output lines that include `syncd` for example, `state=log may_dirty ndr syncd`) to confirm that they are being synchronized by the FGSP.

```
diagnose sys session list
session info: proto=6 proto_state=05 duration=469 expire=0 timeout=3600
flags=00000000 sockflag=00000000 sockport=21 av_idx=0 use=4
origin-shaper=
reply-shaper=
per_ip_shaper=
ha_id=0 policy_dir=0 tunnel=/
state=log may_dirty ndr syncd
statistic(bytes/packets/allow_err): org=544/9/1 reply=621/7/0 tuples=2
origin->sink: org pre->post, reply pre->post dev=46->45/45->46
gwy=10.2.2.1/10.1.1.1
hook=pre dir=org act=noop 192.168.1.50:45327->172.16.1.100:21(0.0.0.0:0)
hook=post dir=reply act=noop 172.16.1.100:21->192.168.1.50:45327(0.0.0.0:0)
pos/(before,after) 0/(0,0), 0/(0,0)
misc=0 policy_id=1 id_policy_id=0 auth_info=0 chk_client_info=0 vd=0
serial=00002deb tos=ff/ff ips_view=1 app_list=2000 app=16427
dd_type=0 dd_mode=0
per_ip_bandwidth meter: addr=192.168.1.50, bps=633
```

Chapter 13 - IPsec VPN

Introduction

This FortiOS Handbook chapter contains the following sections:

[IPsec VPN concepts](#) explains the basic concepts that you need to understand about virtual private networks (VPNs).

[IPsec VPN overview](#) provides a brief overview of IPsec technology and includes general information about how to configure IPsec VPNs using this guide.

[IPsec VPN in the web-based manager](#) describes the IPsec VPN menu of the web-based manager interface.

[Gateway-to-gateway configurations](#) explains how to set up a basic gateway-to-gateway (site-to-site) IPsec VPN. In a gateway-to-gateway configuration, two FortiGate units create a VPN tunnel between two separate private networks.

[Hub-and-spoke configurations](#) describes how to set up hub-and-spoke IPsec VPNs. In a hub-and-spoke configuration, connections to a number of remote peers and/or clients radiate from a single, central FortiGate hub.

[Dynamic DNS configuration](#) describes how to configure a site-to-site VPN, in which one FortiGate unit has a static IP address and the other FortiGate unit has a dynamic IP address and a domain name.

[FortiClient dialup-client configurations](#) guides you through configuring a FortiClient dialup-client IPsec VPN. In a FortiClient dialup-client configuration, the FortiGate unit acts as a dialup server and VPN client functionality is provided by the FortiClient Endpoint Security application installed on a remote host.

[FortiGate dialup-client configurations](#) explains how to set up a FortiGate dialup-client IPsec VPN. In a FortiGate dialup-client configuration, a FortiGate unit with a static IP address acts as a dialup server and a FortiGate unit with a dynamic IP address initiates a VPN tunnel with the FortiGate dialup server.

[Supporting IKE Mode config clients](#) explains how to set up a FortiGate unit as either an IKE Mode Config server or client. IKE Mode Config is an alternative to DHCP over IPsec.

[Internet-browsing configuration](#) explains how to support secure web browsing performed by dialup VPN clients, and hosts behind a remote VPN peer. Remote users can access the private network behind the local FortiGate unit and browse the Internet securely. All traffic generated remotely is subject to the security policy that controls traffic on the private network behind the local FortiGate unit.

[Redundant VPN configurations](#) discusses the options for supporting redundant and partially redundant tunnels in an IPsec VPN configuration. A FortiGate unit can be configured to support redundant tunnels to the same remote peer if the FortiGate unit has more than one interface to the Internet.

[Transparent mode VPNs](#) describes two FortiGate units that create a VPN tunnel between two separate private networks transparently. In transparent mode, all FortiGate unit interfaces except the management interface are invisible at the network layer.

[IPv6 IPsec VPNs](#) describes FortiGate unit VPN capabilities for networks based on IPv6 addressing. This includes IPv4-over-IPv6 and IPv6-over-IPv4 tunnelling configurations. IPv6 IPsec VPNs are available in FortiOS 3.0 MR5 and later.

[L2TP and IPsec \(Microsoft VPN\)](#) explains how to support Microsoft Windows native VPN clients.

[GRE over IPsec \(Cisco VPN\)](#) explains how to interoperate with Cisco VPNs that use Generic Routing Encapsulation (GRE) protocol with IPsec.

[Protecting OSPF with IPsec](#) provides an example of protecting OSPF links with IPsec.

[Redundant OSPF routing over IPsec](#) provides an example of redundant secure communication between two remote networks using an OSPF VPN connection.

[OSPF over dynamic IPsec](#) provides an example of how to create a dynamic IPsec VPN tunnel that allows OSPF.

[BGP over dynamic IPsec](#) provides an example of how to create a dynamic IPsec VPN tunnel that allows BGP.

[Phase 1 parameters](#) provides detailed step-by-step procedures for configuring a FortiGate unit to accept a connection from a remote peer or dialup client. The basic Phase 1 parameters identify the remote peer or clients and support authentication through preshared keys or digital certificates. You can increase VPN connection security further using methods such as extended authentication (XAuth).

[Phase 2 parameters](#) provides detailed step-by-step procedures for configuring an IPsec VPN tunnel. During Phase 2, the specific IPsec security associations needed to implement security services are selected and a tunnel is established.

[Defining VPN security policies](#) explains how to specify the source and destination IP addresses of traffic transmitted through an IPsec VPN tunnel, and how to define a security encryption policy. Security policies control all IP traffic passing between a source address and a destination address.

[Logging and monitoring](#) and [Troubleshooting](#) provide VPN monitoring and troubleshooting procedures.

What's new in FortiOS 6.0.2

IPsec VPN concepts

Virtual Private Network (VPN) technology enables remote users to connect to private computer networks to gain access to their resources in a secure way. For example, an employee traveling or working from home can use a VPN to securely access the office network through the Internet.

Instead of remotely logging on to a private network using an unencrypted and unsecure Internet connection, the use of a VPN ensures that unauthorized parties cannot access the office network and cannot intercept any of the information that is exchanged between the employee and the office. It is also common to use a VPN to connect the private networks of two or more offices.

Fortinet offers VPN capabilities in the FortiGate Unified Threat Management (UTM) appliance and in the FortiClient Endpoint Security suite of applications. A FortiGate unit can be installed on a private network, and FortiClient software can be installed on the user's computer. It is also possible to use a FortiGate unit to connect to the private network instead of using FortiClient software.

This chapter discusses VPN terms and concepts including:

VPN tunnels

The data path between a user's computer and a private network through a VPN is referred to as a tunnel. Like a physical tunnel, the data path is accessible only at both ends. In the telecommuting scenario, the tunnel runs between the FortiClient application on the user's PC, or a FortiGate unit or other network device and the FortiGate unit on the office private network.

Encapsulation makes this possible. IPsec packets pass from one end of the tunnel to the other and contain data packets that are exchanged between the local user and the remote private network. Encryption of the data packets ensures that any third-party who intercepts the IPsec packets can not access the data.

Encoded data going through a VPN tunnel

You can create a VPN tunnel between:

- A PC equipped with the FortiClient application and a FortiGate unit
- Two FortiGate units
- Third-party VPN software and a FortiGate unit

For more information on third-party VPN software, refer to the [Fortinet Knowledge Base](#) for more information.

Tunnel templates

Several tunnel templates are available in the IPsec VPN Wizard that cover a variety of different types of IPsec VPN. A list of these templates appear on the first page of the Wizard, located at **VPN > IPsec Wizard**. The tunnel template list follows.

IPsec VPN Wizard options

VPN Type	Remote Device Type		NAT Options	Description
Site to Site	FortiGate		<ul style="list-style-type: none"> No NAT between sites This site is behind NAT The remote site is behind NAT 	Static tunnel between this FortiGate and a remote FortiGate.
	Cisco		<ul style="list-style-type: none"> No NAT between sites This site is behind NAT The remote site is behind NAT 	Static tunnel between this FortiGate and a remote Cisco firewall.
Remote Access	Client-based	FortiClient VPN for OS X, Windows, and Android	N/A	On-demand tunnel for users using the FortiClient software.
		Cisco AnyConnect	N/A	On-demand tunnel for users using the Cisco IPsec client.
	Native	iOS Native	N/A	On-demand tunnel for iPhone/iPad users using the native iOS IPsec client.
		Android Native	N/A	On-demand tunnel for Android users using the native L2TP/IPsec client.
		Windows Native	N/A	On-demand tunnel for Android users using the native L2TP/IPsec client.
Custom	N/A		N/A	No Template.

Cisco's VPN Client has reached its End-of-Life/End-of-Support as of July 30, 2016, and has been replaced by [Cisco AnyConnect Secure Mobility Client](#).

In FortiOS 5.6.4+, the first step of the VPN Creation Wizard (**VPN > IPsec Wizard**) delineates the **Remote Device Type** (for **Remote Access** templates) between **Client-based** and **Native** in order to distinguish FortiClient and Cisco device options from native OS device options.

VPN tunnel list

Once you create an IPsec VPN tunnel, it appears in the VPN tunnel list at **VPN > IPsec Tunnels**. By default, the tunnel list indicates the name of the tunnel, its interface binding, the tunnel template used, and the tunnel status. If you right-click on the table header row, you can include columns for comments, IKE version, mode (aggressive vs main), phase 2 proposals, and reference number. The tunnel list page also includes the option to create a new tunnel, as well as the options to edit or delete a highlighted tunnel.

FortiView VPN tunnel map

A geospatial map can be found under **FortiView > VPN Map** to help visualize IPsec (and SSL) VPN connections to a FortiGate using Google Maps. This feature adds a geographical-IP API service for resolving spatial locations from IP addresses.

VPN gateways

A gateway is a router that connects the local network to other networks. The default gateway setting in your computer's TCP/IP properties specifies the gateway for your local network.

A VPN gateway functions as one end of a VPN tunnel. It receives incoming IPsec packets, decrypts the encapsulated data packets and passes the data packets to the local network. Also, it encrypts data packets destined for the other end of the VPN tunnel, encapsulates them, and sends the IPsec packets to the other VPN gateway. The VPN gateway is a FortiGate unit because the private network behind it is protected, ensuring the security of the unencrypted VPN data. The gateway can also be FortiClient software running on a PC since the unencrypted data is secure on the PC.

The IP address of a VPN gateway is usually the IP address of the network interface that connects to the Internet. Optionally, you can define a secondary IP address for the interface and use that address as the local VPN gateway address. The benefit of doing this is that your existing setup is not affected by the VPN settings.

The following diagram shows a VPN connection between two private networks with FortiGate units acting as the VPN gateways. This configuration is commonly referred to as Gateway-to-Gateway IPsec VPN.

VPN tunnel between two private networks

Although the IPsec traffic may actually pass through many Internet routers, you can visualize the VPN tunnel as a simple secure connection between the two FortiGate units.

Users on the two private networks do not need to be aware of the VPN tunnel. The applications on their computers generate packets with the appropriate source and destination addresses, as they normally do. The FortiGate units manage all the details of encrypting, encapsulating, and sending the packets to the remote VPN gateway.

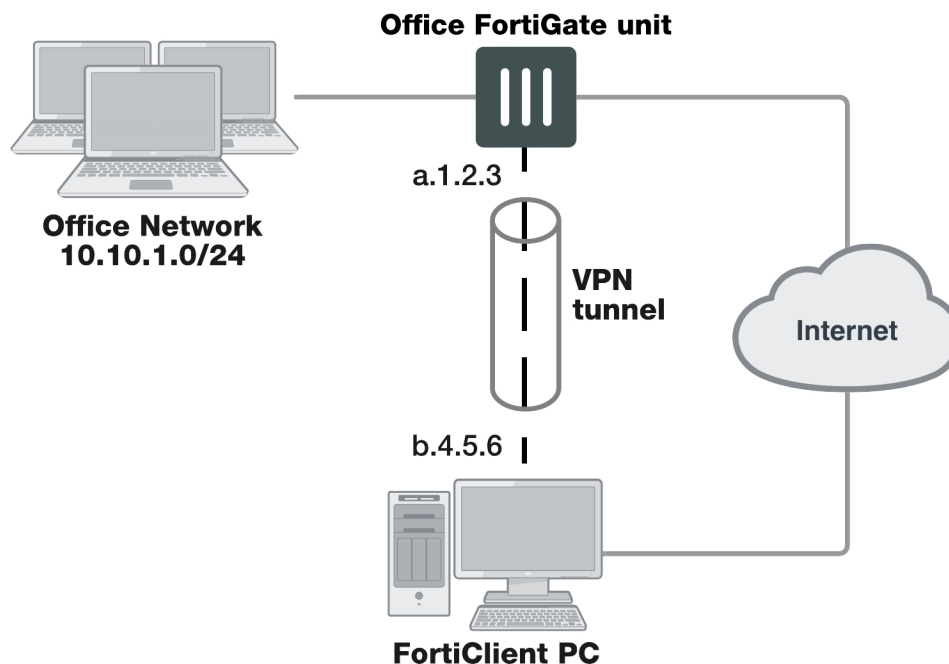

The data is encapsulated in IPsec packets only in the VPN tunnel between the two VPN gateways. Between the user's computer and the gateway, the data is on the secure private network and it is in regular IP packets.

For example User1 on the Site A network, at IP address 10.10.1.7, sends packets with destination IP address 192.168.10.8, the address of User2 on the Site B network. The Site A FortiGate unit is configured to send packets with destinations on the 192.168.10.0 network through the VPN, encrypted and encapsulated. Similarly, the Site B FortiGate unit is configured to send packets with destinations on the 10.10.1.0 network through the VPN tunnel to the Site A VPN gateway.

In the site-to-site, or gateway-to-gateway VPN shown below, the FortiGate units have static (fixed) IP addresses and either unit can initiate communication.

You can also create a VPN tunnel between an individual PC running FortiClient and a FortiGate unit, as shown below. This is commonly referred to as Client-to-Gateway IPsec VPN.

VPN tunnel between a FortiClient PC and a FortiGate unit

On the PC, the FortiClient application acts as the local VPN gateway. Packets destined for the office network are encrypted, encapsulated into IPsec packets, and sent through the VPN tunnel to the FortiGate unit. Packets for other destinations are routed to the Internet as usual. IPsec packets arriving through the tunnel are decrypted to recover the original IP packets.

Clients, servers, and peers

A FortiGate unit in a VPN can have one of the following roles:

- **Server** — responds to a request to establish a VPN tunnel.
- **Client** — contacts a remote VPN gateway and requests a VPN tunnel.
- **Peer** — brings up a VPN tunnel or responds to a request to do so.

The site-to-site VPN shown above is a peer-to-peer relationship. Either FortiGate unit VPN gateway can establish the tunnel and initiate communications. The FortiClient-to-FortiGate VPN shown below is a client-server relationship. The FortiGate unit establishes a tunnel when the FortiClient PC requests one.

A FortiGate unit cannot be a VPN server if it has a dynamically-assigned IP address. VPN clients need to be configured with a static IP address for the server. A FortiGate unit acts as a server only when the remote VPN gateway has a dynamic IP address or is a client-only device or application, such as FortiClient.

As a VPN server, a FortiGate unit can also offer automatic configuration for FortiClient PCs. The user needs to know only the IP address of the FortiGate VPN server and a valid user name/password. FortiClient downloads the VPN configuration settings from the FortiGate VPN server. For information about configuring a FortiGate unit as a VPN server, see the [FortiClient Administration Guide](#).

Encryption

Encryption mathematically transforms data to appear as meaningless random numbers. The original data is called plaintext and the encrypted data is called ciphertext. The opposite process, called decryption, performs the inverse operation to recover the original plaintext from the ciphertext.

The process by which the plaintext is transformed to ciphertext and back again is called an algorithm. All algorithms use a small piece of information, a key, in the arithmetic process of converted plaintext to ciphertext, or vice-versa. IPsec uses symmetrical algorithms, in which the same key is used to both encrypt and decrypt the data. The security of an encryption algorithm is determined by the length of the key that it uses. FortiGate IPsec VPNs offer the following encryption algorithms, in descending order of security:

Encryption	Description
ChaCha20/Poly1305	A combination of the ChaCha20 symmetric cipher and Poly1305-AES, a variant of the AES 128-bit block algorithm that uses a 128-bit key and an 128-bit nonce.
AES-GCM	Galois/Counter Mode (GCM), a block cipher mode of operation providing both confidentiality and data origin authentication.
AES256	A 128-bit block algorithm that uses a 256-bit key.
AES192	A 128-bit block algorithm that uses a 192-bit key.
AES128	A 128-bit block algorithm that uses a 128-bit key.
3DES	Triple-DES, in which plain text is DES-encrypted three times by three keys.
DES	Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key

The default encryption algorithms provided on FortiGate units make recovery of encrypted data almost impossible without the proper encryption keys.

There is a human factor in the security of encryption. The key must be kept secret, known only to the sender and receiver of the messages. Also, the key must not be something that unauthorized parties might easily guess, such as the sender's name, birthday or simple sequence such as 123456.

Diffie-Hellman groups

FortiOS IPsec VPN supports the following Diffie-Hellman (DH) asymmetric key algorithms for public key cryptography.

DH Group	Description
1	More Modular Exponential (MODP) DH Group with a 768-bit modulus
2	MODP with a 1024-bit modulus
5	MODP with a 1536-bit modulus

DH Group	Description
14	MODP with a 2048-bit modulus
15	MODP with a 3027-bit modulus
16	MODP with a 4096-bit modulus
17	MODP with a 6144-bit modulus
18	MODP with a 8192-bit modulus
19	256-bit random elliptic curve group
20	384-bit random elliptic curve group
21	521-bit random elliptic curve group
27	Brainpool 224-bit elliptic curve group
28	Brainpool 256-bit elliptic curve group
29	Brainpool 384-bit elliptic curve group
30	Brainpool 512-bit elliptic curve group
31	Curve25519 128-bit elliptic curve group

* When using aggressive mode, DH groups cannot be negotiated.

By default, DH group 14 is selected, to provide sufficient protection for stronger cipher suites that include AES and SHA2. If you select multiple DH groups, the order they appear in the configuration is the order in which they are negotiated.

If both VPN peers (or a VPN server and its client) have static IP addresses and use aggressive mode, select a single DH group. The setting on the FortiGate unit must be identical to the setting on the remote peer or dialup client.

When the remote VPN peer or client has a dynamic IP address and uses aggressive mode, select up to three DH groups on the FortiGate unit and one DH group on the remote peer or dialup client. The setting on the remote peer or dialup client must be identical to one of the selections on the FortiGate unit.

If the VPN peer or client employs main mode, you can select multiple DH groups. At least one of the settings on the remote peer or dialup client must be identical to the selections on the FortiGate unit.

IPsec overheads

The FortiGate sets an IPsec tunnel Maximum Transmission Unit (MTU) of 1436 for 3DES/SHA1 and an MTU of 1412 for AES128/SHA1, as seen with `diag vpn tunnel list`. This indicates that the FortiGate allocates 64 bytes of overhead for 3DES/SHA1 and 88 bytes for AES128/SHA1, which is the difference if you subtract this MTU from a typical ethernet MTU of 1500 bytes.

During the encryption process, AES/DES operates using a specific size of data which is block size. If data is smaller than that, it will be padded for the operation. MD5/SHA-1 HMAC also operates using a specific block size.

The following table describes the potential maximum overhead for each IPsec encryption:

IPsec Transform Set	IPsec Overhead (Max. bytes)
ESP-AES (256, 192, or 128), ESP-SHA-HMAC, or MD5	88
ESP-AES (256, 192, or 128)	61
ESP-3DES, ESP-DES	45
ESP-(DES or 3DES), ESP-SHA-HMAC, or MD5	64
ESP-Null, ESP-SHA-HMAC, or MD5	45
AH-SHA-HMAC or MD5	44

Authentication

To protect data via encryption, a VPN must ensure that only authorized users can access the private network. You must use either a preshared key on both VPN gateways or RSA X.509 security certificates. The examples in this guide use only preshared key authentication. Refer to the [Fortinet Knowledge Base](#) for articles on RSA X.509 security certificates.

Preshared keys

A preshared key contains at least six random alphanumeric characters. Users of the VPN must obtain the preshared key from the person who manages the VPN server and add the preshared key to their VPN client configuration.

Although it looks like a password, the preshared key, also known as a shared secret, is never sent by either gateway. The preshared key is used in the calculations at each end that generate the encryption keys. As soon as the VPN peers attempt to exchange encrypted data, preshared keys that do not match will cause the process to fail.

Additional authentication

To increase security, you can require additional means of authentication from users, such as:

- An identifier, called a peer ID or a local ID.
- Extended authentication (XAUTH) which imposes an additional user name/password requirement.

A Local ID is an alphanumeric value assigned in the Phase 1 configuration. The Local ID of a peer is called a Peer ID.

In FortiOS 5.2, new authentication methods have been implemented for IKE: ECDSA-256, ECDSA-384, and ECDSA-521. However, AES-XCBC is not supported.

Full CA chain checking

Added a new option (enabled by default) to fail certificate verification if any of the CAs in the trust chain are not found in the CA store. When disabled, a sub-CA is sufficient to pass certificate verification.

Syntax

```
config vpn certificate setting
    set check-ca-chain {enable | disable}
end
```

Phase 1 and Phase 2 settings

A VPN tunnel is established in two phases: Phase 1 and Phase 2. Several parameters determine how this is done. Except for IP addresses, the settings simply need to match at both VPN gateways. There are defaults that are appropriate for most cases.

FortiClient distinguishes between Phase 1 and Phase 2 only in the VPN Advanced settings and uses different terms. Phase 1 is called the IKE Policy. Phase 2 is called the IPsec Policy.

Phase 1

In Phase 1, the two VPN gateways exchange information about the encryption algorithms that they support and then establish a temporary secure connection to exchange authentication information.

When you configure your FortiGate unit or FortiClient application, you must specify the following settings for Phase 1:

Remote gateway	The remote VPN gateway's address. FortiGate units also have the option of operating only as a server by selecting the "Dialup User" option.
Preshared key	This must be the same at both ends. It is used to encrypt Phase 1 authentication information.
Local interface	The network interface that connects to the other VPN gateway. This applies on a FortiGate unit only.

All other Phase 1 settings have default values. These settings mainly configure the types of encryption to be used. The default settings on FortiGate units and in the FortiClient application are compatible. The examples in this guide use these defaults.

For more detailed information about Phase 1 settings, see [Phase 1 parameters on page 1655](#).

Phase 2

Similar to the Phase 1 process, the two VPN gateways exchange information about the encryption algorithms that they support for Phase 2. You may choose different encryption for Phase 1 and Phase 2. If both gateways have at least one encryption algorithm in common, a VPN tunnel can be established. Keep in mind that more algorithms each phase does not share with the other gateway, the longer negotiations will take. In extreme cases this may cause timeouts during negotiations.

To configure default Phase 2 settings on a FortiGate unit, you need only select the name of the corresponding Phase 1 configuration. In FortiClient, no action is required to enable default Phase 2 settings.

For more detailed information about Phase 2 settings, see [Phase 2 parameters on page 1675](#).

Security Association

The establishment of a Security Association (SA) is the successful outcome of Phase 1 negotiations. Each peer maintains a database of information about VPN connections. The information in each SA can include cryptographic algorithms and keys, keylife, and the current packet sequence number. This information is kept synchronized as the VPN operates. Each SA has a Security Parameter Index (SPI) that is provided to the remote peer at the time the SA is established. Subsequent IPsec packets from the peer always reference the relevant SPI. It is possible for peers to have multiple VPNs active simultaneously, and correspondingly multiple SPIs.

The IPsec SA connect message generated is used to install dynamic selectors. These selectors can be installed via the auto-negotiate mechanism. When phase 2 has auto-negotiate enabled, and phase 1 has mesh selector-type set to **subnet**, a new dynamic selector will be installed for each combination of source and destination subnets. Each dynamic selector will inherit the auto-negotiate option from the template selector and begin SA negotiation. Phase 2 selector sources from dial-up clients will all establish SAs without traffic being initiated from the client subnets to the hub.

Remote IP address change detection

SAs are stored in a hash table when keyed off the IPsec SA SPI value. This enables the FortiGate, for each inbound ESP packet received, to immediately look up the SA and compare the stored IP address against the one in the incoming packet. If the incoming and stored IP addresses differ, an IP address change can be made in the kernel SA, and an update event can be triggered for IKE.

IKE and IPsec packet processing

Internet Key Exchange (IKE) is the protocol used to set up SAs in IPsec negotiation. As described in [Phase 1 parameters on page 1655](#), you can optionally choose IKEv2 over IKEv1 if you configure a route-based IPsec VPN. IKEv2 simplifies the negotiation process, in that it provides no choice of Aggressive or Main mode in Phase 1. IKEv2 also uses less bandwidth.

The following sections identify how IKE versions 1 and 2 operate and differentiate.

IKEv1

Phase 1

A peer, identified in the IPsec policy configuration, begins the IKE negotiation process. This IKE Security Association (SA) agreement is known as Phase 1. The Phase 1 parameters identify the remote peer or clients and supports authentication through pre-shared key (PSK) or digital certificate. You can increase access security further using peer identifiers, certificate distinguished names, group names, or the FortiGate extended authentication (XAuth) option for authentication purposes. Basically, Phase 1 authenticates a remote peer and sets up a secure communication channel for establishing Phase 2, which negotiates the IPsec SA.

IKE Phase 1 can occur in either Main mode or Aggressive mode. For more information, see [Phase 1 parameters on page 1655](#).

IKE Phase 1 is successful only when the following are true:

- Each peer negotiates a matching IKE SA policy.
- Each peer is authenticated and their identities protected.
- The Diffie-Hellman exchange is authenticated (the pre-shared secret keys match).

For more information on Phase 1, see [Phase 1 parameters on page 1655](#).

Phase 2

Phase 2 parameters define the algorithms that the FortiGate unit can use to encrypt and transfer data for the remainder of the session in an IPsec SA. The basic Phase 2 settings associate IPsec Phase 2 parameters with a Phase 1 configuration.

In Phase 2, the VPN peer or client and the FortiGate unit exchange keys again to establish a more secure communication channel. The Phase 2 Proposal parameters select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of the SA. The keys are generated automatically using a Diffie-Hellman algorithm.

In Phase 2, Quick mode selectors determine which IP addresses can perform IKE negotiations to establish a tunnel. By only allowing authorized IP addresses access to the VPN tunnel, the network is more secure. For more information, see [Phase 2 parameters on page 1675](#).

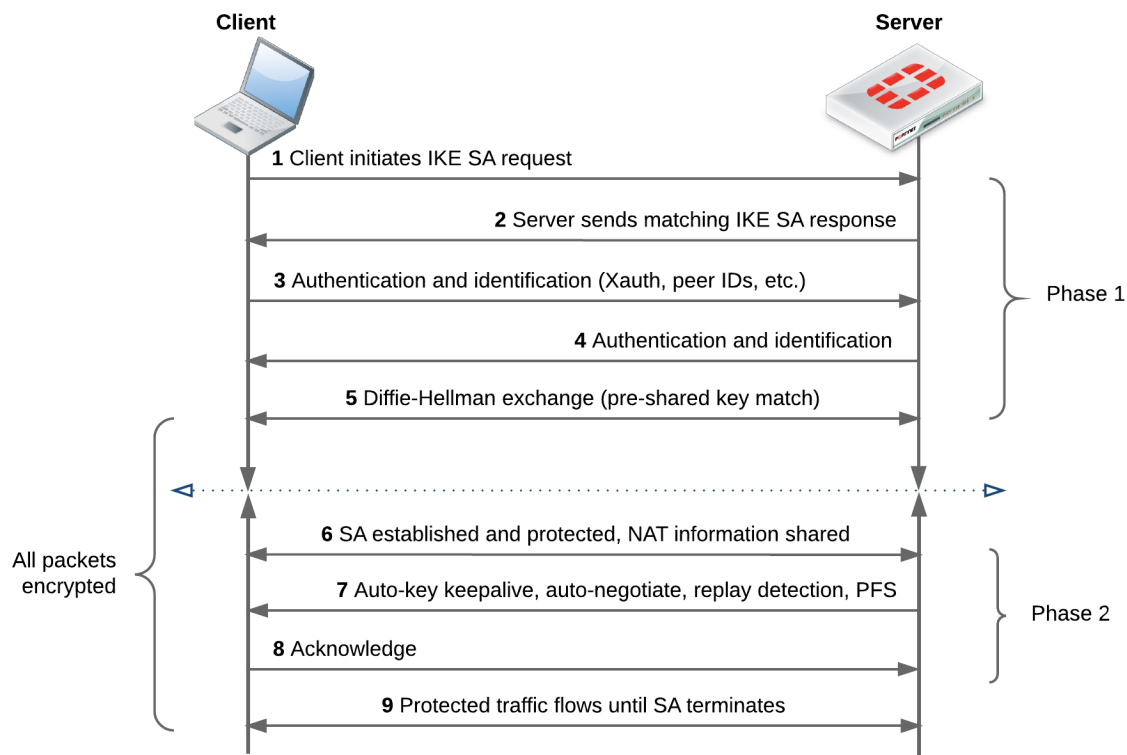

IKE Phase 2 is successful only when the following are true:

- The IPsec SA is established and protected by the IKE SA.
- The IPsec SA is configured to renegotiate after set durations (see [Phase 2 parameters on page 1675](#) and [Phase 2 parameters on page 1675](#)).
- **Optional:** Replay Detection is enabled. Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel. See [Phase 2 parameters on page 1675](#).
- **Optional:** Perfect Forward Secrecy (PFS) is enabled. PFS improves security by forcing a new Diffie-Hellman exchange whenever keylife expires. See [Phase 2 parameters on page 1675](#).

For more information on Phase 2, see [Phase 2 parameters on page 1675](#).

With Phase 2 established, the IPsec tunnel is fully negotiated and traffic between the peers is allowed until the SA terminates (for any number of reasons; time-out, interruption, disconnection, etc).

The entire IKEv1 process is demonstrated in the following diagram:

IKEv2

Phase 1

Unlike Phase 1 of IKEv1, IKEv2 does not provide options for Aggressive or Main mode. Furthermore, Phase 1 of IKEv2 begins immediately with an IKE SA initiation, consisting of only two packets (containing all the information typically contained in four packets for IKEv1), securing the channel such that all following transactions are encrypted (see [Phase 1 parameters on page 1655](#)).

The encrypted transactions contain the IKE authentication, since remote peers have yet to be authenticated. This stage of IKE authentication in IKEv2 can loosely be called Phase 1.5.

Phase 1.5

As part of this phase, IKE authentication must occur. IKE authentication consists of the following:

- The authentication payloads and Internet Security Association and Key Management Protocol (ISAKMP) identifier.
- The authentication method (RSA, PSK, ECDSA, or EAP).
- The IPsec SA parameters.

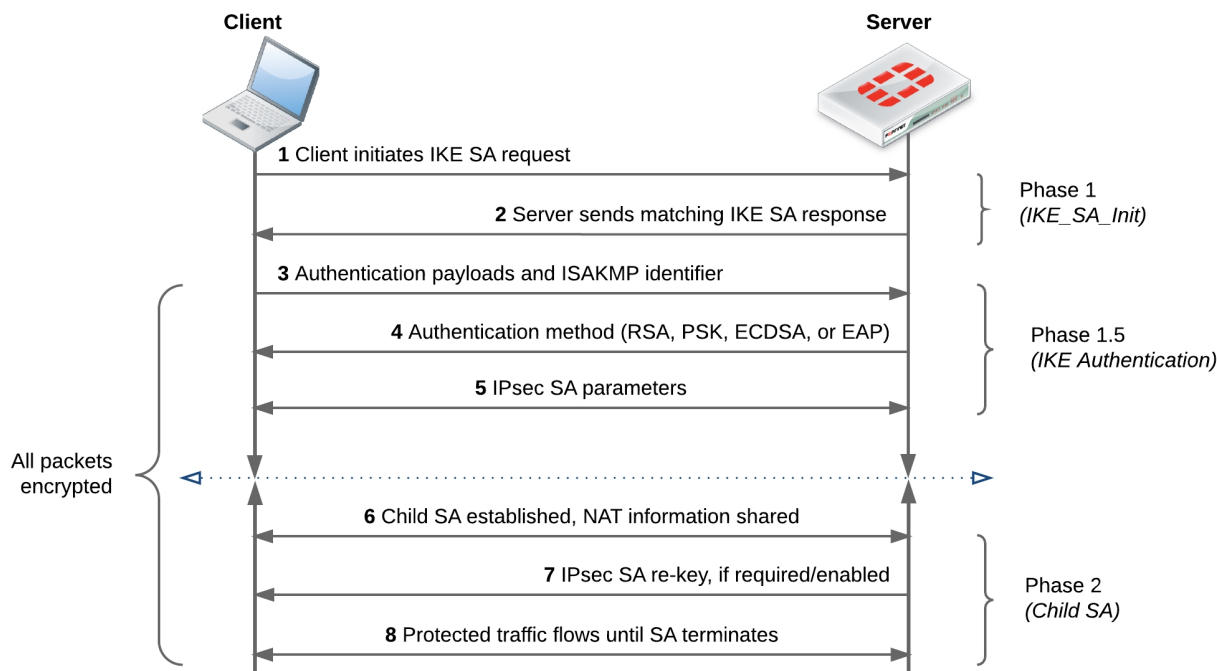

Due to the number of authentication methods potentially used, and SAs established, the overall IKEv2 negotiation can range from 4 packets (no EAP exchange at all) to many more.

At this point, both peers have a security association complete and ready to encrypt traffic.

Phase 2

In IKEv1, Phase 2 uses Quick mode to negotiate an IPsec SA between peers. In IKEv2, since the IPsec SA is already established, Phase 2 is essentially only used to negotiate “child” SAs, or to re-key an IPsec SA. That said, there are only two packets for each exchange of this type, similar to the exchange at the outset of Phase 1.5.

The entire IKEv2 process is demonstrated in the following diagram:

Support for IKEv2 session resumption

If a gateway loses connectivity to the network, clients can attempt to re-establish the lost session by presenting the ticket to the gateway (as described in [RFC 5723](#)). As a result, sessions can be resumed much faster, as DH exchange that is necessary to establish a brand new connection is skipped. This feature implements "ticket-by-value", whereby all information necessary to restore the state of a particular IKE SA is stored in the ticket and sent to the client.

IKEv2 asymmetric authentication

Asymmetric authentication allows both sides of an authentication exchange to use different authentication methods, for example the initiator may be using a shared key, while the responder may have a public signature key and certificate.

The command `authmethod-remote` is available under `config vpn ipsec phase1-interface`.

For more detailed information on authentication of the IKE SA, see [RFC 5996 - Internet Key Exchange Protocol Version 2 \(IKEv2\)](#).

IKEv2 Digital Signature Authentication support

FortiOS supports the use of Digital Signature authentication, which changes the format of the Authentication Data payload in order to support different signature methods.

Instead of just containing a raw signature value calculated as defined in the original IKE RFCs, the Auth Data now includes an ASN.1 formatted object that provides details on how the signature was calculated, such as the signature type, hash algorithm, and signature padding method.

For more detailed information on IKEv2 Digital Signature authentication, see [RFC 7427 - Signature Authentication in the Internet Key Exchange Version 2 \(IKEv2\)](#).

Unique IKE identifiers

When enabled, the following `phase1` CLI command (`enforce-unique-id`) requires all IPsec VPN clients to use a unique identifier when connecting.

CLI syntax

```
config vpn ipsec phase1
  edit <name>
    set enforce-unique-id {keep-new | keep-old | disable} Default is disable.
  next
end
```

Use `keep-new` to replace the old connection if an ID collision is detected on the gateway.

Use `keep-old` to reject the new connection if an ID collision is detected.

IKEv2 ancillary RADIUS group authentication

This feature provides for the IDi information to be extracted from the IKEv2 AUTH exchange and sent to a RADIUS server, along with a fixed password (configurable via CLI only), to perform an additional group authentication step prior to tunnel establishment. The RADIUS server may return framed-IP-address, framed-ip-netmask, and dns-server attributes, which are then applied to the tunnel.

It should be noted, unlike Xauth or EAP, this feature does not perform individual user authentication, but rather treats all users on the gateway as a single group, and authenticates that group with RADIUS using a fixed password. This feature also works with RADIUS accounting, including the `phase1 acct-verify` option.

Syntax

```
config vpn ipsec phase1-interface
  edit <name>
    set mode-cfg enable
    set type dynamic
    set ike-version 2
    set group-authentication {enable | disable}
    set group-authentication-secret <password>
  next
end
```

IPsec VPN overview

This section provides a brief overview of IPsec technology and includes general information about how to configure IPsec VPNs using this guide.

The following topics are included in this section:

VPN configurations interact with the firewall component of the FortiGate unit. There must be a security policy in place to permit traffic to pass between the private network and the VPN tunnel.

Security policies for VPNs specify:

- The FortiGate interface that provides the physical connection to the remote VPN gateway, usually an interface connected to the Internet
- The FortiGate interface that connects to the private network
- IP addresses associated with data that has to be encrypted and decrypted
- Optionally, a schedule that restricts when the VPN can operate
- Optionally, the services (types of data) that can be sent

When the first packet of data that meets all of the conditions of the security policy arrives at the FortiGate unit, a VPN tunnel may be initiated and the encryption or decryption of data is performed automatically afterward. For more information, see [Defining VPN security policies on page 1](#).

Where possible, you should create route-based VPNs. Generally, route-based VPNs are more flexible and easier to configure than policy-based VPNs — by default they are treated as interfaces. However, these two VPN types have different requirements that limit where they can be used.

Types of VPNs

FortiGate unit VPNs can be policy-based or route-based. There is little difference between the two types. In both cases, you specify Phase 1 and Phase 2 settings. However there is a difference in implementation. A route-based VPN creates a virtual IPsec network interface that applies encryption or decryption as needed to any traffic that it carries. That is why route-based VPNs are also known as interface-based VPNs. A policy-based VPN is implemented through a special security policy that applies the encryption you specified in the Phase 1 and Phase 2 settings.

Route-based VPNs

For a route-based VPN, you create two security policies between the virtual IPsec interface and the interface that connects to the private network. In one policy, the virtual interface is the source. In the other policy, the virtual interface is the destination. This creates bidirectional policies that ensure traffic will flow in both directions over the VPN.

A route-based VPN is also known as an interface-based VPN.

Each route-based IPsec VPN tunnel requires a virtual IPsec interface. As such, the amount of possible route-based IPsec VPNs is limited by the **system.interface** table size. The **system.interface** table size for most devices is 8192.

For a complete list of table sizes for all devices, refer to the [Maximum Values](#) table.

Policy-based VPNs

For a policy-based VPN, one security policy enables communication in both directions. You enable inbound and outbound traffic as needed within that policy, or create multiple policies of this type to handle different types of traffic differently. For example HTTPS traffic may not require the same level of scanning as FTP traffic.

A policy-based VPN is also known as a tunnel-mode VPN.

Comparing policy-based or route-based VPNs

For both VPN types you create Phase 1 and Phase 2 configurations. Both types are handled in the stateful inspection security layer, assuming there is no IPS or AV. For more information on the three security layers, see the [FortiOS Troubleshooting guide](#).

The main difference is in the security policy.

You create a policy-based VPN by defining an IPSEC security policy between two network interfaces and associating it with the VPN tunnel (Phase 1) configuration.

You create a route-based VPN by creating a virtual IPsec interface. You then define a regular ACCEPT security policy to permit traffic to flow between the virtual IPsec interface and another network interface. And lastly, configure a static route to allow traffic over the VPN.

Where possible, you should create route-based VPNs. Generally, route-based VPNs are more flexible and easier to configure than policy-based VPNs — by default they are treated as interfaces. However, these two VPN types have different requirements that limit where they can be used.

Comparison of policy-based and route-based VPNs

Features	Policy-based	Route-based
Both NAT and transparent modes available	Yes	NAT mode only
L2TP-over-IPsec supported	Yes	Yes
GRE-over-IPsec supported	No	Yes
security policy requirements	Requires a security policy with IPSEC action that specifies the VPN tunnel	Requires only a simple security policy with ACCEPT action
Number of policies per VPN	One policy controls connections in both directions	A separate policy is required for connections in each direction

Planning your VPN

It is a good idea to plan the VPN configuration ahead of time. This will save time later and help you configure your VPN correctly.

All VPN configurations are comprised of numerous required and optional parameters. Before you begin, you need to determine:

- Where the IP traffic originates and where it needs to be delivered
- Which hosts, servers, or networks to include in the VPN
- Which VPN devices to include in the configuration
- Through which interfaces the VPN devices communicate
- Through which interfaces do private networks access the VPN gateways

Once you have this information, you can select a VPN topology that suits the network environment.

Network topologies

The topology of your network will determine how remote peers and clients connect to the VPN and how VPN traffic is routed.

VPN network topologies and brief descriptions

Topology	Description
Gateway-to-gateway configurations	Standard one-to-one VPN between two FortiGate units. See Gateway-to-gateway configurations on page 1 .
Hub-and-spoke configurations	One central FortiGate unit has multiple VPNs to other remote FortiGate units. See Hub-and-spoke configurations on page 1 .
Dynamic DNS configuration	One end of the VPN tunnel has a changing IP address and the other end must go to a dynamic DNS server for the current IP address before establishing a tunnel. See Dynamic DNS configuration on page 1 .
FortiClient dialup-client configurations	Typically remote FortiClient dialup-clients use dynamic IP addresses through NAT devices. The FortiGate unit acts as a dialup server allowing dialup VPN connections from multiple sources. See FortiClient dialup-client configurations on page 1 .
FortiGate dialup-client configurations	Similar to FortiClient dialup-client configurations but with more gateway-to-gateway settings such as unique user authentication for multiple users on a single VPN tunnel. See FortiGate dialup-client configurations on page 1 .
Internet-browsing configuration	Secure web browsing performed by dialup VPN clients, and/or hosts behind a remote VPN peer. See Internet-browsing configuration on page 1 .
Redundant VPN configurations	Options for supporting redundant and partially redundant IPsec VPNs, using route-based approaches. See Redundant VPN configurations on page 1 .
Transparent mode VPNs	In transparent mode, the FortiGate acts as a bridge with all incoming traffic being broadcast back out on all other interfaces. Routing and NAT must be performed on external routers. See Transparent mode VPNs on page 1 .
L2TP and IPsec (Microsoft VPN)	Configure VPN for Microsoft Windows dialup clients using the built in L2TP software. Users do not have to install any See L2TP and IPsec (Microsoft VPN) on page 1 .

These sections contain high-level configuration guidelines with cross-references to detailed configuration procedures. If you need more detail to complete a step, select the cross-reference in the step to drill-down to more detail. Return to the original procedure to complete the procedure. For a general overview of how to configure a VPN, see [Planning your VPN](#).

General preparation steps

A VPN configuration defines relationships between the VPN devices and the private hosts, servers, or networks making up the VPN. Configuring a VPN involves gathering and recording the following information. You will need this information to configure the VPN.

- **The private IP addresses of participating hosts, servers, and/or networks.** These IP addresses represent the source addresses of traffic that is permitted to pass through the VPN. A IP source address can be an individual IP address, an address range, or a subnet address.
- **The public IP addresses of the VPN end-point interfaces.** The VPN devices establish tunnels with each other through these interfaces.
- **The private IP addresses associated with the VPN-device interfaces to the private networks.** Computers on the private networks behind the VPN gateways will connect to their VPN gateways through these interfaces.

How to use this guide to configure an IPsec VPN

This guide uses a task-based approach to provide all of the procedures needed to create different types of VPN configurations. Follow the step-by-step configuration procedures in this guide to set up the VPN.

The following configuration procedures are common to all IPsec VPNs:

1. Define the Phase 1 parameters that the FortiGate unit needs to authenticate remote peers or clients and establish a secure connection. See [Phase 1 parameters on page 1655](#).
2. Define the Phase 2 parameters that the FortiGate unit needs to create a VPN tunnel with a remote peer or dialup client. See [Phase 2 parameters on page 1675](#).
3. Specify the source and destination addresses of IP packets that are to be transported through the VPN tunnel. See [Defining policy addresses on page 1](#).
4. Create an IPsec security policy to define the scope of permitted services between the IP source and destination addresses. See [Defining VPN security policies on page 1](#).

These steps assume you configure the FortiGate unit to generate unique IPsec encryption and authentication keys automatically. In situations where a remote VPN peer or client requires a specific IPsec encryption and authentication key, you must configure the FortiGate unit to use manual keys instead of performing Steps 1 and 2.

IPsec VPN in the web-based manager

To configure an IPsec VPN, use the general procedure below. With these steps, your FortiGate unit will automatically generate unique IPsec encryption and authentication keys. If a remote VPN peer or client requires a specific IPsec encryption or authentication key, you must configure your FortiGate unit to use manual keys instead.

1. Define Phase 1 parameters to authenticate remote peers and clients for a secure connection. See [IPsec VPN in the web-based manager on page 1642](#).
2. Define Phase 2 parameters to create a VPN tunnel with a remote peer or dialup client. See [IPsec VPN in the web-based manager on page 1642](#).
3. Create a security policy to permit communication between your private network and the VPN. Policy-based VPNs have an action of IPSEC, where for interface-based VPNs the security policy action is ACCEPT. See [Defining VPN security policies on page 1](#).

The FortiGate unit implements the Encapsulated Security Payload (ESP) protocol. Internet Key Exchange (IKE) is performed automatically based on pre-shared keys or X.509 digital certificates. Interface mode, supported in NAT mode only, creates a virtual interface for the local end of a VPN tunnel.

This chapter contains the following sections:

Phase 1 configuration

To begin defining the Phase 1 configuration, go to **VPN > IPsec Tunnels** and select **Create New**. Enter a unique descriptive name for the VPN tunnel and follow the instructions in the VPN Creation Wizard.

The Phase 1 configuration mainly defines the ends of the IPsec tunnel. The remote end is the remote gateway with which the FortiGate unit exchanges IPsec packets. The local end is the FortiGate interface that sends and receives IPsec packets.

If you want to control how the IKE negotiation is processed when there is no traffic, as well as the length of time the FortiGate unit waits for negotiations to occur, you can use the `negotiation-timeout` and `auto-negotiate` commands in the CLI.

For more information, refer to [Phase 2 parameters on page 1675](#) and [Phase 2 parameters on page 1675](#).

Name	<p>Type a name for the Phase 1 definition. The maximum name length is 15 characters for an interface mode VPN, 35 characters for a policy-based VPN. If Remote Gateway is Dialup User, the maximum name length is further reduced depending on the number of dialup tunnels that can be established: by 2 for up to 9 tunnels, by 3 for up to 99 tunnels, 4 for up to 999 tunnels, and so on.</p> <p>For a tunnel mode VPN, the name normally reflects where the remote connection originates. For a route-based tunnel, the FortiGate unit also uses the name for the virtual IPsec interface that it creates automatically.</p>
-------------	---

Remote Gateway	<p>Select the category of the remote connection:</p> <p>Static IP Address — If the remote peer has a static IP address.</p> <p>Dialup User — If one or more FortiClient or FortiGate dialup clients with dynamic IP addresses will connect to the FortiGate unit.</p> <p>Dynamic DNS — If a remote peer that has a domain name and subscribes to a dynamic DNS service will connect to the FortiGate unit.</p>
IP Address	If you selected Static IP Address , enter the IP address of the remote peer.
Dynamic DNS	If you selected Dynamic DNS , enter the domain name of the remote peer.
Local Interface	<p>This option is available in NAT mode only. Select the name of the interface through which remote peers or dialup clients connect to the FortiGate unit.</p> <p>By default, the local VPN gateway IP address is the IP address of the interface that you selected.</p>
Mode	<p>Main mode — the Phase 1 parameters are exchanged in multiple rounds with encrypted authentication information.</p> <p>Aggressive mode — the Phase 1 parameters are exchanged in single message with authentication information that is not encrypted.</p> <p>When the remote VPN peer has a dynamic IP address and is authenticated by a pre-shared key, you must select Aggressive mode if there is more than one dialup phase1 configuration for the interface IP address.</p> <p>When the remote VPN peer has a dynamic IP address and is authenticated by a certificate, you must select Aggressive mode if there is more than one Phase 1 configuration for the interface IP address and these Phase 1 configurations use different proposals.</p>
Authentication Method	Select Preshared Key or RSA Signature .
Pre-shared Key	<p>If you selected Pre-shared Key, enter the pre-shared key that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during Phase 1 negotiations. You must define the same key at the remote peer or client.</p> <p>The key must contain at least 6 printable characters. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters. The limit is 128 characters.</p>

Certificate Name	If you selected RSA Signature , select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during Phase 1 negotiations. For information about obtaining and loading the required server certificate, see the FortiOS User Authentication guide .
Peer Options	Peer options are available to authenticate VPN peers or clients, depending on the Remote Gateway and Authentication Method settings.
Any peer ID	<p>Accept the local ID of any remote VPN peer or client. The FortiGate unit does not check identifiers (local IDs). You can set Mode to Aggressive or Main.</p> <p>You can use this option with RSA Signature authentication. But, for highest security, configure a PKI user/group for the peer and set Peer Options to Accept this peer certificate only.</p>
This peer ID	<p>This option is available when Aggressive Mode is enabled. Enter the identifier that is used to authenticate the remote peer. This identifier must match the Local ID that the remote peer's administrator has configured.</p> <p>If the remote peer is a FortiGate unit, the identifier is specified in the Local ID field of the Advanced Phase 1 configuration.</p> <p>If the remote peer is a FortiClient user, the identifier is specified in the Local ID field, accessed by selecting Config in the Policy section of the VPN connection's Advanced Settings.</p> <p>In circumstances where multiple remote dialup VPN tunnels exist, each tunnel must have a peer ID set.</p>
Peer ID from dialup group	<p>Authenticate multiple FortiGate or FortiClient dialup clients that use unique identifiers and unique pre-shared keys (or unique pre-shared keys only) through the same VPN tunnel.</p> <p>You must create a dialup user group for authentication purposes. Select the group from the list next to the Peer ID from dialup group option.</p> <p>You must set Mode to Aggressive when the dialup clients use unique identifiers and unique pre-shared keys. If the dialup clients use unique pre-shared keys only, you can set Mode to Main if there is only one dialup Phase 1 configuration for this interface IP address.</p>

Phase 1 advanced configuration settings

You can use the following advanced parameters to select the encryption and authentication algorithms that the FortiGate unit uses to generate keys for the IKE exchange. You can also use the following advanced parameters to ensure the smooth operation of Phase 1 negotiations.

These settings are mainly configured in the CLI, although some options are available after the tunnel is created using the VPN Creation Wizard (using the **Convert to Custom Tunnel** option).

If the FortiGate unit will act as a VPN client, and you are using security certificates for authentication, set the **Local ID** to the distinguished name (DN) of the local server certificate that the FortiGate unit will use for authentication purposes.

Note that, since FortiOS 5.4, an exact match is required to optimize IKE's gateway search utilizing binary trees. However, it is also possible to have partial matching of 'user.peer:cn' to match peers to gateways by performing a secondary match. When IKE receives IDi of type ASN1.DN, the first search is done with the whole DN string. If none is found, IKE will extract just the CN attribute value and perform a second search.

VXLAN over IPsec

Packets with VXLAN header are encapsulated within IPsec tunnel mode.

To configure VXLAN over IPsec - CLI:

```
config vpn ipsec phase1-interface/phase1
edit ipsec
set interface <name>
set encapsulation vxlan/gre
set encapsulation-address ike/ipv4/ipv6
set encap-local-gw4 xxx.xxx.xxx.xxx
set encap-remote-gw xxx.xxx.xxx.xxx
next
end
```

You can define an idle timer for IPsec tunnels. When no traffic has passed through the tunnel for the configured idle-timeout value, the IPsec tunnel will be flushed.

To configure IPsec tunnel idle timeout - CLI:

IPsec tunnel idle timer

```
config vpn ipsec phase1-interface
edit p1
set idle-timeout [enable | disable]
set idle-timeoutinterval <integer> //IPsec tunnel
idle timeout in minutes (10 - 43200).
end
end
```

IPv6 Version

Select if you want to use IPv6 addresses for the remote gateway and interface IP addresses.

Specify an IP address for the local end of the VPN tunnel. Select one of the following:

Local Gateway IP

Main Interface IP — The FortiGate unit obtains the IP address of the interface from the network interface settings.

Specify — Enter a secondary address of the interface selected in the Phase 1 **Local Interface** field.

You cannot configure Interface mode in a transparent mode VDOM.

Phase 1 Proposal

Select the encryption and authentication algorithms used to generate keys for protecting negotiations and add encryption and authentication algorithms as required.

You need to select a minimum of one and a maximum of three combinations. The remote peer or client must be configured to use at least one of the proposals that you define.

Select one of the following symmetric-key encryption algorithms:

DES — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key.

3DES — Triple-DES; plain text is encrypted three times by three keys.

AES128 — A 128-bit block algorithm that uses a 128-bit key.

AES192 — A 128-bit block algorithm that uses a 192-bit key.

AES256 — A 128-bit block algorithm that uses a 256-bit key.

ChaCha20/Poly1305 — A 128-bit block algorithm that uses a 128-bit key and a symmetric cipher. Only available for IKEv2.

You can select either of the following message digests to check the authenticity of messages during an encrypted session:

MD5 — Message Digest 5.

SHA1 — Secure Hash Algorithm 1 - a 160-bit message digest.

To specify one combination only, set the **Encryption** and **Authentication** options of the second combination to NULL. To specify a third combination, use the **Add** button beside the fields for the second combination.

Diffie-Hellman Group

Select one or more Diffie-Hellman groups from DH groups 1, 2, 5, and 14 through 21. At least one of the **Diffie-Hellman Group** settings on the remote peer or client must match one the selections on the FortiGate unit. Failure to match one or more DH groups will result in failed negotiations.

Keylife

Enter the time (in seconds) that must pass before the IKE encryption key expires. When the key expires, a new key is generated without interrupting service. The keylife can be from 120 to 172 800 seconds.

Local ID

If the FortiGate unit will act as a VPN client and you are using peer IDs for authentication purposes, enter the identifier that the FortiGate unit will supply to the VPN server during the Phase 1 exchange.

If the FortiGate unit will act as a VPN client, and you are using security certificates for authentication, select the distinguished name (DN) of the local server certificate that the FortiGate unit will use for authentication purposes.

If the FortiGate unit is a dialup client and will not be sharing a tunnel with other dialup clients (that is, the tunnel will be dedicated to this Fortinet dialup client), set **Mode** to **Aggressive**.

Note that this Local ID value must match the peer ID value given for the remote VPN peer's Peer Options.

XAuth

This option supports the authentication of dialup clients. It is available for IKE v1 only.

Disable — Select if you do not use XAuth.

Enable as Client — If the FortiGate unit is a dialup client, enter the user name and password that the FortiGate unit will need to authenticate itself to the remote XAuth server.

Enable as Server — This is available only if **Remote Gateway** is set to **Dialup User**. Dialup clients authenticate as members of a dialup user group. You must first create a user group for the dialup clients that need access to the network behind the FortiGate unit.

You must also configure the FortiGate unit to forward authentication requests to an external RADIUS or LDAP authentication server.

Select a **Server Type** setting to determine the type of encryption method to use between the FortiGate unit, the XAuth client and the external authentication server, and then select the user group from the User Group list.

Username

Enter the user name that is used for authentication.

Password

Enter the password that is used for authentication.

NAT Traversal

Select the check box if a NAT device exists between the local FortiGate unit and the VPN peer or client. The local FortiGate unit and the VPN peer or client must have the same NAT traversal setting (both selected or both cleared) to connect reliably.

Additionally, you can force IPsec to use NAT traversal. If NAT is set to **Forced**, the FortiGate will use a port value of zero when constructing the NAT discovery hash for the peer. This causes the peer to think it is behind a NAT device, and it will use UDP encapsulation for IPsec, even if no NAT is present. This approach maintains interoperability with any IPsec implementation that supports the NAT-T RFC.

Keepalive Frequency

If you enabled **NAT-traversal**, enter a keepalive frequency setting.

Dead Peer Detection

Select this check box to reestablish VPN tunnels on idle connections and clean up dead IKE peers if required. You can use this option to receive notification whenever a tunnel goes up or down, or to keep the tunnel connection open when no traffic is being generated inside the tunnel. For example, in scenarios where a dialup client or dynamic DNS peer connects from an IP address that changes periodically, traffic may be suspended while the IP address changes.

With **Dead Peer Detection** selected, you can use the `config vpn ipsec phase1 (tunnel mode)` or `config vpn ipsec phase1-interface (interface mode)` CLI command to optionally specify a retry count and a retry interval.

IKEv1 fragmentation

UDP fragmentation can cause issues in IPsec when either the ISP or perimeter firewall(s) cannot pass or fragment the oversized UDP packets that occur when using a very large public security key (PSK). The result is that IPsec tunnels do not come up. The solution is IKE fragmentation.

For most configurations, enabling IKE fragmentation allows connections to automatically establish when they otherwise might have failed due to intermediate nodes dropping IKE messages containing large certificates, which typically push the packet size over 1500 bytes.

FortiOS will fragment a packet on sending if, and only if, all the following are true:

- Phase 1 contains "set fragmentation enable".
- The packet is larger than the minimum MTU (576 for IPv4, 1280 for IPv6).
- The packet is being re-transmitted.

By default, IKE fragmentation is enabled, but upon upgrading, any existing phase1-interface may have have "set fragmentation disable" added in order to preserve the existing behaviour of not supporting fragmentation.

Enabling or disabling IKE fragmentation - CLI

```
config vpn ipsec phase1-interface
  edit 1
    set fragmentation [enable | disable]
  next
end
```

IKEv2 fragmentation

With IKEv2, because [RFC 7383](#) requires each fragment to be individually encrypted and authenticated, we would have to keep a copy of the unencrypted payloads around for each outgoing packet, in case the original single packet was never answered and we wanted to retry with fragments. With the following implementation, if the IKE payloads are greater than a configured threshold, the IKE packets are preemptively fragmented and encrypted.

CLI syntax

```
config vpn ipsec phase1-interface
    edit ike
        set ike-version 2
        set fragmentation [enable|disable]
        set fragmentation-mtu [500-16000]
    next
end
```

Phase 2 configuration

After IPsec Phase 1 negotiations end successfully, you begin Phase 2. You can configure the Phase 2 parameters to define the algorithms that the FortiGate unit may use to encrypt and transfer data for the remainder of the session. During Phase 2, you select specific IPsec security associations needed to implement security services and establish a tunnel.

The basic Phase 2 settings associate IPsec Phase 2 parameters with the Phase 1 configuration that specifies the remote end point of the VPN tunnel. In most cases, you need to configure only basic Phase 2 settings.

These settings are mainly configured in the CLI, although some options are available after the tunnel is created using the VPN Creation Wizard (using the **Convert to Custom Tunnel** option).

Name	Type a name to identify the Phase 2 configuration.
Phase 1	Select the Phase 1 tunnel configuration. For more information on configuring Phase 1, see Phase 1 configuration on page 1642 . The Phase 1 configuration describes how remote VPN peers or clients will be authenticated on this tunnel, and how the connection to the remote peer or client will be secured.
Advanced	Define advanced Phase 2 parameters. For more information, see Phase 2 advanced configuration settings below.

Phase 2 advanced configuration settings

In Phase 2, the FortiGate unit and the VPN peer or client exchange keys again to establish a secure communication channel between them. You select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of Security Associations (SAs). These are called Phase 2 Proposal parameters. The keys are generated automatically using a Diffie-Hellman algorithm.

You can use a number of additional advanced Phase 2 settings to enhance the operation of the tunnel.

Phase 2 Proposal	<p>Select the encryption and authentication algorithms that will be proposed to the remote VPN peer. You can specify up to three proposals. To establish a VPN connection, at least one of the proposals that you specify must match configuration on the remote peer.</p> <p>Initially there are two proposals. Add and Delete icons are next to the second Authentication field.</p> <p>It is invalid to set both Encryption and Authentication to NULL.</p>
Encryption	<p>Select a symmetric-key algorithms:</p> <p>NULL — Do not use an encryption algorithm.</p> <p>DES — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key.</p> <p>3DES — Triple-DES; plain text is encrypted three times by three keys.</p> <p>AES128 — A 128-bit block algorithm that uses a 128-bit key.</p> <p>AES192 — A 128-bit block algorithm that uses a 192-bit key.</p> <p>AES256 — A 128-bit block algorithm that uses a 256-bit key.</p> <p>ChaCha20/Poly1305 — A 128-bit block algorithm that uses a 128-bit key and a symmetric cipher. Only available for IKEv2.</p>
Authentication	<p>You can select either of the following message digests to check the authenticity of messages during an encrypted session:</p> <p>NULL — Do not use a message digest.</p> <p>MD5 — Message Digest 5.</p> <p>SHA1 — Secure Hash Algorithm 1 - a 160-bit message digest.</p> <p>To specify one combination only, set the Encryption and Authentication options of the second combination to NULL. To specify a third combination, use the Add button beside the fields for the second combination.</p>
Enable replay detection	Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel.
Enable perfect forward secrecy (PFS)	Perfect forward secrecy (PFS) improves security by forcing a new Diffie-Hellman exchange whenever keylife expires.
Diffie-Hellman Group	Select one Diffie-Hellman group (1, 2, 5, or 14 through 21). This must match the DH Group that the remote peer or dialup client uses.
Keylife	<p>Select the method for determining when the Phase 2 key expires: Seconds, KBytes, or Both. If you select Both, the key expires when either the time has passed or the number of KB have been processed.</p>
Autokey Keep Alive	Select the check box if you want the tunnel to remain active when no data is being processed.

Auto-negotiate	Enable the option if you want the tunnel to be automatically renegotiated when the tunnel expires.
DHCP-IPsec	<p>Provide IP addresses dynamically to VPN clients. This is available for Phase 2 configurations associated with a dialup Phase 1 configuration.</p> <p>You also need configure a DHCP server or relay on the private network interface. You must configure the DHCP parameters separately.</p> <p>If you configure the DHCP server to assign IP addresses based on RADIUS user group attributes, you must also set the Phase 1 Peer Options to Peer ID from dialup group and select the appropriate user group. See Phase 1 configuration on page 1642.</p> <p>If the FortiGate unit acts as a dialup server and you manually assigned FortiClient dialup clients VIP addresses that match the network behind the dialup server, selecting the check box will cause the FortiGate unit to act as a proxy for the dialup clients.</p>
Quick Mode Selector	<p>Specify the source and destination IP addresses to be used as selectors for IKE negotiations. If the FortiGate unit is a dialup server, keep the default value of 0.0.0.0/0 unless you need to circumvent problems caused by ambiguous IP addresses between one or more of the private networks making up the VPN. You can specify a single host IP address, an IP address range, or a network address. You may optionally specify source and destination port numbers and a protocol number.</p> <p>If you are editing an existing Phase 2 configuration, the Source address and Destination address fields are unavailable if the tunnel has been configured to use firewall addresses as selectors. This option exists only in the CLI.</p>
Source address	<p>If the FortiGate unit is a dialup server, enter the source IP address that corresponds to the local senders or network behind the local VPN peer (for example, 172.16.5.0/24 or 172.16.5.0/255.255.255.0 for a subnet, or 172.16.5.1/32 or 172.16.5.1/255.255.255.255 for a server or host, or 192.168.10.[80-100] or 192.168.10.80-192.168.10.100 for an address range). A value of 0.0.0.0/0 means all IP addresses behind the local VPN peer.</p> <p>If the FortiGate unit is a dialup client, source address must refer to the private network behind the Fortinet dialup client.</p>
Source port	Enter the port number that the local VPN peer uses to transport traffic related to the specified service (protocol number). The range is from 0 to 65535. To specify all ports, type 0.

Destination address	Enter the destination IP address that corresponds to the recipients or network behind the remote VPN peer (for example, 192.168.20.0/24 for a subnet, or 172.16.5.1/32 for a server or host, or 192.168.10.[80-100] for an address range). A value of 0.0.0.0/0 means all IP addresses behind the remote VPN peer.
Destination port	Enter the port number that the remote VPN peer uses to transport traffic related to the specified service (protocol number). To specify all ports, enter 0.
Protocol	Enter the IP protocol number of the service. To specify all services, enter 0.

FortiClient VPN

Use the **FortiClient VPN for OS X, Windows, and Android** VPN Wizard option when configuring an IPsec VPN for remote users to connect to the VPN tunnel using FortiClient.

When configuring a FortiClient VPN connection, the settings for Phase 1 and Phase 2 settings are automatically configured by the FortiGate unit. They are set to:

- Remote Gateway — Dialup User
- Mode — Aggressive
- Default settings for Phase 1 and 2 Proposals
- XAUTH Enable as Server (Auto)
- IKE mode-config will be enabled
- Peer Option — “Any peer ID”

The remainder of the settings use the current FortiGate defaults. Note that FortiClient settings need to match these FortiGate defaults. If you need to configure advanced settings for the FortiClient VPN, you must do so using the CLI.

Name	Enter a name for the FortiClient VPN.
Local Outgoing Interface	Select the local outgoing interface for the VPN.
Authentication Method	Select the type of authentication used when logging in to the VPN.
Preshared Key	If Pre-shared Key was selected in Authentication Method , enter the pre-shared key in the field provided.
User Group	Select a user group. You can also create a user group from the drop-down list by selecting Create New .
Address Range Start IP	Enter the start IP address for the DHCP address range for the client.
Address Range End IP	Enter the end IP address for the address range.
Subnet Mask	Enter the subnet mask.

Enable IPv4 Split Tunnel	Enabled by default, this option enables the FortiClient user to use the VPN to access internal resources while other Internet access is not sent over the VPN, alleviating potential traffic bottlenecks in the VPN connection. Disable this option to have all traffic sent through the VPN tunnel.
Accessible Networks	Select from a list of internal networks that the FortiClient user can access.
Client Options	<p>These options affect how the FortiClient application behaves when connected to the FortiGate VPN tunnel. When enabled, a check box for the corresponding option appears on the VPN login screen in FortiClient, and is not enabled by default.</p> <p>Save Password - When enabled, if the user selects this option, their password is stored on the user's computer and will automatically populate each time they connect to the VPN.</p> <p>Auto Connect - When enabled, if the user selects this option, when the FortiClient application is launched, for example after a reboot or system startup, FortiClient will automatically attempt to connect to the VPN tunnel.</p> <p>Always Up (Keep Alive) - When enabled, if the user selects this option, the FortiClient connection will not shut down. When not selected, during periods of inactivity, FortiClient will attempt to stay connected every three minutes for a maximum of 10 minutes.</p>
Endpoint Registration	<p>When selected, the FortiGate unit requests a registration key from FortiClient before a connection can be established. A registration key is defined by going to System > Advanced.</p> <p>For more information on FortiClient VPN connections to a FortiGate unit, see the FortiClient Administration Guide.</p>
DNS Server	<p>Select which DNS server to use for this VPN:</p> <p>Use System DNS — Use the same DNS servers as the FortiGate unit. These are configured at Network > DNS. This is the default option.</p> <p>Specify — Specify the IP address of a different DNS server.</p>

Concentrator

In a hub-and-spoke configuration, policy-based VPN connections to a number of remote peers radiate from a single, central FortiGate unit. Site-to-site connections between the remote peers do not exist; however, you can establish VPN tunnels between any two of the remote peers through the FortiGate unit's "hub".

In a hub-and-spoke network, all VPN tunnels terminate at the hub. The peers that connect to the hub are known as "spokes". The hub functions as a concentrator on the network, managing all VPN connections between the spokes. VPN traffic passes from one tunnel to the other through the hub.

You define a concentrator to include spokes in the hub-and-spoke configuration. You create the concentrator in **VPN > IPsec Concentrator** and select **Create New**. A concentrator configuration specifies which spokes to include in an IPsec hub-and-spoke configuration.

Concentrator Name	Type a name for the concentrator.
Available Tunnels	A list of defined IPsec VPN tunnels. Select a tunnel from the list and then select the right arrow.
Members	A list of tunnels that are members of the concentrator. To remove a tunnel from the concentrator, select the tunnel and select the left arrow.

IPsec Monitor

You can use the IPsec Monitor to view activity on IPsec VPN tunnels and start or stop those tunnels. The display provides a list of addresses, proxy IDs, and timeout information for all active tunnels, including tunnel mode and route-based (interface mode) tunnels.

To view the IPsec monitor, go to **Monitor > IPsec Monitor**.

Tunnels are considered as "up" if at least one phase 2 selector is active. To avoid confusion, when a tunnel is down, **IPsec Monitor** will keep the **Phase 2 Selectors** column, but hide it by default and be replaced with **Phase 1** status column.

For dialup VPNs, the list provides status information about the VPN tunnels established by dialup clients, and their IP addresses.

For static IP or dynamic DNS VPNs, the list provides status and IP addressing information about VPN tunnels, active or not, to remote peers that have static IP addresses or domain names. You can also start and stop individual tunnels from the list.

Timeout field in IPsec Monitor page

The **Timeout** field in **Monitor > IPsec Monitor** shows the realtime timeout value for each VPN tunnel that is **Up** (tunnels that are **Down** show a timeout value of **0**).

Phase 1 parameters

This chapter provides detailed step-by-step procedures for configuring a FortiGate unit to accept a connection from a remote peer or dialup client. The Phase 1 parameters identify the remote peer or clients and supports authentication through preshared keys or digital certificates. You can increase access security further using peer identifiers, certificate distinguished names, group names, or the FortiGate extended authentication (XAuth) option for authentication purposes.

For more information on Phase 1 parameters in the web-based manager, see [IPsec VPN in the web-based manager on page 1642](#).

The information and procedures in this section do not apply to VPN peers that perform negotiations using manual keys.

The following topics are included in this section:

Overview

To configure IPsec Phase 1 settings, go to **VPN > IPsec Tunnels** and edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).

IPsec Phase 1 settings define:

- The remote and local ends of the IPsec tunnel
- If Phase 1 parameters are exchanged in multiple rounds with encrypted authentication information (main mode) or in a single message with authentication information that is not encrypted (aggressive mode)
- If a preshared key or digital certificates will be used to authenticate the FortiGate unit to the VPN peer or dialup client
- If the VPN peer or dialup client is required to authenticate to the FortiGate unit. A remote peer or dialup client can authenticate by peer ID or, if the FortiGate unit authenticates by certificate, it can authenticate by peer certificate.
- The IKE negotiation proposals for encryption and authentication
- Optional XAuth authentication, which requires the remote user to enter a user name and password. A FortiGate VPN server can act as an XAuth server to authenticate dialup users. A FortiGate unit that is a dialup client can also be configured as an XAuth client to authenticate itself to the VPN server.

For all the Phase 1 web-based manager fields, see [IPsec VPN in the web-based manager on page 1642](#).

If you want to control how IKE is negotiated when there is no traffic, as well as the length of time the unit waits for negotiations to occur, use the `negotiation-timeout` and `auto-negotiate` commands in the CLI.

Defining the tunnel ends

To begin defining the Phase 1 configuration, go to **VPN > IPsec Tunnels** and select **Create New**. Enter a unique descriptive name for the VPN tunnel and follow the instructions in the VPN Creation Wizard.

The Phase 1 configuration mainly defines the ends of the IPsec tunnel. The remote end is the remote gateway with which the FortiGate unit exchanges IPsec packets. The local end is the FortiGate interface that sends and receives IPsec packets.

The remote gateway can be:

- A static IP address
- A domain name with a dynamic IP address
- A dialup client

A statically addressed remote gateway is the simplest to configure. You specify the IP address. Unless restricted in the security policy, either the remote peer or a peer on the network behind the FortiGate unit can bring up the tunnel.

If the remote peer has a domain name and subscribes to a dynamic DNS service, you need to specify only the domain name. The FortiGate unit performs a DNS query to determine the appropriate IP address. Unless restricted in the security policy, either the remote peer or a peer on the network behind the FortiGate unit can bring up the tunnel.

If the remote peer is a dialup client, only the dialup client can bring up the tunnel. The IP address of the client is not known until it connects to the FortiGate unit. This configuration is a typical way to provide a VPN for client PCs running VPN client software such as the FortiClient Endpoint Security application.

The local end of the VPN tunnel, the Local Interface, is the FortiGate interface that sends and receives the IPsec packets. This is usually the public interface of the FortiGate unit that is connected to the Internet (typically the WAN1 port). Packets from this interface pass to the private network through a security policy.

By default, the local VPN gateway is the IP address of the selected Local Interface. If you are configuring an interface mode VPN, you can optionally use a secondary IP address of the Local Interface as the local gateway.

Choosing Main mode or Aggressive mode

The FortiGate unit and the remote peer or dialup client exchange Phase 1 parameters in either Main mode or Aggressive mode. This choice does not apply if you use IKE version 2, which is available only for route-based configurations.

- In **Main** mode, the Phase 1 parameters are exchanged in multiple rounds with encrypted authentication information
- In **Aggressive** mode, the Phase 1 parameters are exchanged in a single message with unencrypted authentication information.

Although Main mode is more secure, you must select Aggressive mode if there is more than one dialup Phase 1 configuration for the interface IP address, and the remote VPN peer or client is authenticated using an identifier local ID. Aggressive mode might not be as secure as Main mode, but the advantage to Aggressive mode is that it is faster than Main mode (since fewer packets are exchanged). Aggressive mode is typically used for remote access VPNs. But you would also use aggressive mode if one or both peers have dynamic external IP addresses. Descriptions of the peer options in this guide indicate whether Main or Aggressive mode is required.

Choosing the IKE version

If you create a route-based VPN, you have the option of selecting IKE version 2. Otherwise, IKE version 1 is used.

IKEv2, defined in [RFC 4306](#), simplifies the negotiation process that creates the security association (SA).

If you select IKEv2:

- There is no choice in Phase 1 of Aggressive or Main mode.
- Extended Authentication (XAUTH) is not available.
- You can select only one Diffie-Hellman Group.
- You can utilize EAP and MOBIKE.

Repeated authentication in IKEv2

This feature provides the option to control whether a device requires its peer to re-authenticate or whether re-key is sufficient. It does not influence the re-authentication or re-key behavior of the device itself, which is controlled by the peer (with the default being to re-key). This solution is in response to [RFC 4478](#). As described by the IETF, "the purpose of this is to limit the time that security associations (SAs) can be used by a third party who has gained control of the IPsec peer".

Syntax

```
config vpn ipsec phase1-interface
    edit p1
        set reauth [enable | disable]
    next
end
```

IKEv2 cookie notification for IKE_SA_INIT

IKEv2 offers an optional exchange within IKE_SA_INIT (the initial exchange between peers when establishing a secure tunnel) as a result of an inherent vulnerability in IPsec implementations, as described in [RFC 5996](#).

Two expected attacks against IKE are state and CPU exhaustion, where the target is flooded with session initiation requests from forged IP addresses. These attacks can be made less effective if a responder uses minimal CPU and commits no state to an SA until it knows the initiator can receive packets at the address from which it claims to be sending them.

If the IKE_SA_INIT response includes the cookie notification, the initiator MUST then retry the IKE_SA_INIT request, and include the cookie notification containing the received data as the first payload, and all other payloads unchanged.

Upon detecting that the number of half-open IKEv2 SAs is above the threshold value, the VPN dialup server requires all future SA_INIT requests to include a valid cookie notification payload that the server sends back, in order to preserve CPU and memory resources.

For most devices, the threshold value is set to 500, half of the maximum 1,000 connections.

This feature is enabled by default in FortiOS 5.4.

IKEv2 Quick Crash Detection

There is support for IKEv2 Quick Crash Detection (QCD) as described in [RFC 6290](#).

RFC 6290 describes a method in which an IKE peer can quickly detect that the gateway peer that it has and established an IKE session with has rebooted, crashed, or otherwise lost IKE state. When the gateway receives IKE messages or ESP packets with unknown IKE or IPsec SPIs, the IKEv2 protocol allows the gateway to send the peer an unprotected IKE message containing INVALID_IKE_SPI or INVALID_SPI notification payloads.

RFC 6290 introduces the concept of a QCD token, which is generated from the IKE SPIs and a private QCD secret, and exchanged between peers during the protected IKE AUTH exchange.

Adding Quick Crash Detection - CLI Syntax

```
config system settings
    set ike-quick-crash-detect [enable | disable]
end
```

IKEv1 Quick Crash Detection

Based on the IKEv2 QCD feature described above, IKEv1 QCD is implemented using a new IKE vendor ID, "Fortinet Quick Crash Detection", and so both endpoints must be FortiGate devices. The QCD token is sent in the Phase 1 exchange and must be encrypted, so this is only implemented for IKEv1 in Main mode (Aggressive mode is not supported as there is no available AUTH message in which to include the token).

Otherwise, the feature works the same as in IKEv2 (RFC 6290).

Authenticating the FortiGate unit

The FortiGate unit can authenticate itself to remote peers or dialup clients using either a pre-shared key or an RSA Signature (certificate).

Authenticating the FortiGate unit with digital certificates

To authenticate the FortiGate unit using digital certificates, you must have the required certificates installed on the remote peer and on the FortiGate unit. The signed server certificate on one peer is validated by the presence of the root certificate installed on the other peer. If you use certificates to authenticate the FortiGate unit, you can also require the remote peers or dialup clients to authenticate using certificates.

For more information about obtaining and installing certificates, see the [FortiOS User Authentication guide](#).

Authenticating the FortiGate unit using digital certificates

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button):

Name	Enter a name that reflects the origination of the remote connection. For interface mode, the name can be up to 15 characters long.
Remote Gateway	<p>Select the nature of the remote connection.</p> <p>Each option changes the available fields you must configure. For more information, see Authenticating the FortiGate unit on page 1658.</p>
Local Interface	Select the interface that is the local end of the IPsec tunnel. For more information, see Authenticating the FortiGate unit on page 1658 . The local interface is typically the WAN1 port.
Mode	<p>Select a mode. It is easier to use Aggressive mode.</p> <p>In Main mode, parameters are exchanged in multiple encrypted rounds.</p> <p>In Aggressive mode, parameters are exchanged in a single unencrypted message.</p> <p>Aggressive mode must be used when the remote VPN peer or client has a dynamic IP address, or the remote VPN peer or client will be authenticated using an identifier (local ID).</p> <p>For more information, see Authenticating the FortiGate unit on page 1658.</p>

Authentication Method	Select Signature .
Certificate Name	<p>Select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during Phase 1 negotiations.</p> <p>You must obtain and load the required server certificate before this selection. See the FortiOS User Authentication guide. If you have not loaded any certificates, use the certificate named Fortinet_Factory.</p>
Peer Options	<p>Peer options define the authentication requirements for remote peers or dialup clients. They are not for your FortiGate unit itself.</p> <p>See Authenticating the FortiGate unit on page 1658.</p>
Advanced	<p>You can use the default settings for most Phase 1 configurations. Changes are required only if your network requires them. These settings includes IKE version, DNS server, P1 proposal encryption and authentication settings, and XAuth settings. See Authenticating the FortiGate unit on page 1658.</p>

3. If you are configuring authentication parameters for a dialup user group, optionally define extended authentication (XAuth) parameters in the Advanced section. See [Authenticating the FortiGate unit on page 1658](#).
4. Select **OK**.

Authenticating the FortiGate unit with a pre-shared key

The simplest way to authenticate a FortiGate unit to its remote peers or dialup clients is by means of a pre-shared key. This is less secure than using certificates, especially if it is used alone, without requiring peer IDs or extended authentication (XAuth). Also, you need to have a secure way to distribute the pre-shared key to the peers.

If you use pre-shared key authentication alone, all remote peers and dialup clients must be configured with the same pre-shared key. Optionally, you can configure remote peers and dialup clients with unique pre-shared keys. On the FortiGate unit, these are configured in user accounts, not in the phase_1 settings. For more information, see [Authenticating the FortiGate unit on page 1658](#).

The pre-shared key must contain at least 6 printable characters and best practices dictate that it be known only to network administrators. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.

If you authenticate the FortiGate unit using a pre-shared key, you can require remote peers or dialup clients to authenticate using peer IDs, but not client certificates.

Authenticating the FortiGate unit with a pre-shared key

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button):

Name	Enter a name that reflects the origination of the remote connection.
-------------	--

Remote Gateway	Select the nature of the remote connection. For more information, see Authenticating the FortiGate unit on page 1658 .
Local Interface	Select the interface that is the local end of the IPsec tunnel. For more information, see Authenticating the FortiGate unit on page 1658 . The local interface is typically the WAN1 port.
Mode	<p>Select Main or Aggressive mode.</p> <p>In Main mode, the Phase 1 parameters are exchanged in multiple rounds with encrypted authentication information.</p> <p>In Aggressive mode, the Phase 1 parameters are exchanged in single message with authentication information that is not encrypted.</p> <p>When the remote VPN peer or client has a dynamic IP address, or the remote VPN peer or client will be authenticated using an identifier (local ID), you must select Aggressive mode if there is more than one dialup Phase 1 configuration for the interface IP address.</p> <p>For more information, see Authenticating the FortiGate unit on page 1658.</p>
Authentication Method	Select Pre-shared Key .
Pre-shared Key	Enter the preshared key that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during Phase 1 negotiations. You must define the same value at the remote peer or client. The key must contain at least 6 printable characters and best practices dictate that it only be known by network administrators. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.
Peer options	Peer options define the authentication requirements for remote peers or dialup clients, not for the FortiGate unit itself. You can require the use of peer IDs, but not client certificates. For more information, see Authenticating the FortiGate unit on page 1658 .
Advanced	You can retain the default settings unless changes are needed to meet your specific requirements. See Authenticating the FortiGate unit on page 1658 .

3. If you are configuring authentication parameters for a dialup user group, optionally define extended authentication (XAuth) parameters. See [Authenticating the FortiGate unit on page 1658](#).
4. Select **OK**.

Authenticating remote peers and clients

Certificates or pre-shared keys restrict who can access the VPN tunnel, but they do not identify or authenticate the remote peers or dialup clients. You have the following options for authentication:

Methods of authenticating remote VPN peers

Certificates or Pre-shared key	Local ID	User account pre-shared keys	Reference
Certificates			See Enabling VPN access for specific certificate holders on page 1661 .
Either	X		See Enabling VPN access by peer identifier on page 1663 .
Pre-shared key		X	See Enabling VPN access with user accounts and pre-shared keys on page 1664 .
Pre-shared key	X	X	See Enabling VPN access with user accounts and pre-shared keys on page 1664 .

Repeated authentication in Internet Key Exchange (IKEv2) protocol

This feature provides the option to control whether a device requires its peer to re-authenticate or whether re-key is sufficient. It does not influence the re-authentication or re-key behavior of the device itself, which is controlled by the peer (with the default being to re-key).

This solution is in response to [RFC 4478](#). This solution is intended to limit the time that security associations (SAs) can be used by a third party who has gained control of the IPsec peer.

CLI syntax:

```
config vpn ipsec phase1-interface
edit p1
    set reauth [enable | disable]
next
end
```

disable: Disable IKE SA re-authentication.

enable: Enable IKE SA re-authentication.

Enabling VPN access for specific certificate holders

When a VPN peer or dialup client is configured to authenticate using digital certificates, it sends the Distinguished Name (DN) of its certificate to the FortiGate unit. This DN can be used to allow VPN access for the certificate holder. That is, a FortiGate unit can be configured to deny connections to all remote peers and dialup clients except the one having the specified DN.

Before you begin

The following procedures assume that you already have an existing Phase 1 configuration (see [Authenticating remote peers and clients on page 1660](#)). Follow the procedures below to add certificate-based authentication parameters to the existing configuration.

Before you begin, you must obtain the certificate DN of the remote peer or dialup client. If you are using the FortiClient application as a dialup client, refer to FortiClient online help for information about how to view the certificate DN. To view the certificate DN of a FortiGate unit, see [Viewing server certificate information and obtaining the local DN on page 1662](#).

Use the `config user peer` CLI command to load the DN value into the FortiGate configuration. For example, if a remote VPN peer uses server certificates issued by your own organization, you would enter information similar to the following:

```
config user peer
  edit DN_FG1000
    set cn 192.168.2.160
    set cn-type ipv4
  end
```

The value that you specify to identify the entry (for example, DN_FG1000) is displayed in the **Accept this peer certificate only** list in the IPsec Phase 1 configuration when you return to the web-based manager.

If the remote VPN peer has a CA-issued certificate to support a higher level of credibility, you would enter information similar to the following in the CLI:

```
config user peer
  edit CA_FG1000
    set ca CA_Cert_1
    set subject FG1000_at_site1
  end
```

The value that you specify to identify the entry (for example, CA_FG1000) is displayed in the **Accept this peer certificate only** list in the IPsec Phase 1 configuration when you return to the web-based manager. For more information about these CLI commands, see the “user” chapter of the [FortiGate CLI Reference](#).

A group of certificate holders can be created based on existing user accounts for dialup clients. To create the user accounts for dialup clients, see the “User” chapter of the [FortiGate Administration Guide](#). To create the certificate group afterward, use the `config user peergrp` CLI command. See the “user” chapter of the [FortiGate CLI Reference](#).

Viewing server certificate information and obtaining the local DN

1. Go to **System > Certificates**.
2. Note the CN value in the **Subject** field (for example, CN = 172.16.10.125, CN = info@fortinet.com, or CN = www.example.com).

Viewing CA root certificate information and obtaining the CA certificate name

1. Go to **System > Certificates > CA Certificates**.
2. Note the value in the **Name** column (for example, CA_Cert_1).

Configuring certificate authentication for a VPN

With peer certificates loaded, peer users and peer groups defined, you can configure your VPN to authenticate users by certificate.

Enabling access for a specific certificate holder or a group of certificate holders

1. At the FortiGate VPN server, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. From the **Authentication Method** list, select **RSA Signature**.
4. From the **Certificate Name** list, select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client
5. Under **Peer Options**, select one of these options:
 - To accept a specific certificate holder, select **Accept this peer certificate only** and select the name of the certificate that belongs to the remote peer or dialup client. The certificate DN must be added to the FortiGate configuration through CLI commands before it can be selected here. See [Before you begin on page 1662](#).
 - To accept dialup clients who are members of a certificate group, select **Accept this peer certificate group only** and select the name of the group. The group must be added to the FortiGate configuration through CLI commands before it can be selected here. See [Before you begin on page 1662](#).
6. If you want the FortiGate VPN server to supply the DN of a local server certificate for authentication purposes, select **Advanced** and then from the **Local ID** list, select the DN of the certificate that the FortiGate VPN server is to use.
7. Select **OK**.

Enabling VPN access by peer identifier

Whether you use certificates or pre-shared keys to authenticate the FortiGate unit, you can require that remote peers or clients have a particular peer ID. This adds another piece of information that is required to gain access to the VPN. More than one FortiGate/FortiClient dialup client may connect through the same VPN tunnel when the dialup clients share a preshared key and assume the same identifier.

In circumstances where multiple remote dialup VPN tunnels exist, each tunnel must have a peer ID set.

A peer ID, also called local ID, can be up to 63 characters long containing standard regular expression characters. Local ID is set in phase1 Aggressive Mode configuration.

You cannot require a peer ID for a remote peer or client that uses a pre-shared key and has a static IP address.

Authenticating remote peers or dialup clients using one peer ID

1. At the FortiGate VPN server, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Select **Aggressive** mode in any of the following cases:

- The FortiGate VPN server authenticates a FortiGate dialup client that uses a dedicated tunnel
 - A FortiGate unit has a dynamic IP address and subscribes to a dynamic DNS service
 - FortiGate/FortiClient dialup clients sharing the same preshared key and local ID connect through the same VPN tunnel
4. For the **Peer Options**, select **This peer ID** and type the identifier into the corresponding field.
 5. Select **OK**.

Assigning an identifier (local ID) to a FortiGate unit

Use this procedure to assign a peer ID to a FortiGate unit that acts as a remote peer or dialup client.

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Select **Advanced**.
4. In the **Local ID** field, type the identifier that the FortiGate unit will use to identify itself.
5. Set **Mode** to **Aggressive** if any of the following conditions apply:
 - The FortiGate unit is a dialup client that will use a unique ID to connect to a FortiGate dialup server through a dedicated tunnel.
 - The FortiGate unit has a dynamic IP address, subscribes to a dynamic DNS service, and will use a unique ID to connect to the remote VPN peer through a dedicated tunnel.
 - The FortiGate unit is a dialup client that shares the specified ID with multiple dialup clients to connect to a FortiGate dialup server through the same tunnel.
6. Select **OK**.

Configuring the FortiClient application

Follow this procedure to add a peer ID to an existing FortiClient configuration:

1. Start the FortiClient application.
2. Go to **VPN > Connections**, select the existing configuration.
3. Select **Advanced > Edit > Advanced**.
4. Under **Policy**, select **Config**.
5. In the **Local ID** field, type the identifier that will be shared by all dialup clients. This value must match the **This peer ID** value that you specified previously in the Phase 1 gateway configuration on the FortiGate unit.
6. Select **OK** to close all dialog boxes.
7. Configure all dialup clients the same way using the same preshared key and local ID.

Enabling VPN access with user accounts and pre-shared keys

You can permit access only to remote peers or dialup clients that have pre-shared keys and/or peer IDs configured in user accounts on the FortiGate unit.

If you want two VPN peers (or a FortiGate unit and a dialup client) to accept reciprocal connections based on peer IDs, you must enable the exchange of their identifiers when you define the Phase 1 parameters.

The following procedures assume that you already have an existing Phase 1 configuration (see [Authenticating remote peers and clients on page 1660](#)). Follow the procedures below to add ID checking to the existing configuration.

Before you begin, you must obtain the identifier (local ID) of the remote peer or dialup client. If you are using the FortiClient Endpoint Security application as a dialup client, refer to the Authenticating FortiClient Dialup Clients Technical Note to view or assign an identifier. To assign an identifier to a FortiGate dialup client or a FortiGate unit that has a dynamic IP address and subscribes to a dynamic DNS service, see [Assigning an identifier \(local ID\) to a FortiGate unit on page 1664](#).

If required, a dialup user group can be created from existing user accounts for dialup clients. To create the user accounts and user groups, see the [User Authentication](#) handbook chapter.

The following procedure supports FortiGate/FortiClient dialup clients that use unique preshared keys and/or peer IDs. The client must have an account on the FortiGate unit and be a member of the dialup user group.

The dialup user group must be added to the FortiGate configuration before it can be selected. For more information, see the [User Authentication](#) handbook chapter.

The FortiGate dialup server compares the local ID that you specify at each dialup client to the FortiGate user-account user name. The dialup-client preshared key is compared to a FortiGate user-account password.

Authenticating dialup clients using unique preshared keys and/or peer IDs

1. At the FortiGate VPN server, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. If the clients have unique peer IDs, set **Mode** to **Aggressive**.
4. Clear the **Pre-shared Key** field.
The user account password will be used as the preshared key.
5. Select **Peer ID from dialup group** and then select the group name from the list of user groups.
6. Select **OK**.

Follow this procedure to add a unique pre-shared key and unique peer ID to an existing FortiClient configuration.

Configuring FortiClient - pre-shared key and peer ID

1. Start the FortiClient Endpoint Security application.
2. Go to **VPN > Connections**, select the existing configuration.
3. Select **Advanced > Edit**.
4. In the **Preshared Key** field, type the FortiGate password that belongs to the dialup client (for example, 1234546).
The user account password will be used as the preshared key.
5. Select **Advanced**.
6. Under **Policy**, select **Config**.
7. In the **Local ID** field, type the FortiGate user name that you assigned previously to the dialup client (for example, FortiClient1).
8. Select **OK** to close all dialog boxes.

Configure all FortiClient dialup clients this way using unique preshared keys and local IDs.

Follow this procedure to add a unique pre-shared key to an existing FortiClient configuration.

Configuring FortiClient - preshared key only

1. Start the FortiClient Endpoint Security application.
2. Go to **VPN > Connections**, select the existing configuration

3. Select **Advanced > Edit**.
4. In the **Preshared Key** field, type the user name, followed by a “+” sign, followed by the password that you specified previously in the user account settings on the FortiGate unit (for example, FC2+1FG6LK).
5. Select **OK** to close all dialog boxes.

Configure all the FortiClient dialup clients this way using their unique peer ID and pre-shared key values.

Defining IKE negotiation parameters

In Phase 1, the two peers exchange keys to establish a secure communication channel between them. As part of the Phase 1 process, the two peers authenticate each other and negotiate a way to encrypt further communications for the duration of the session. The Phase 1 Proposal parameters select the encryption and authentication algorithms that are used to generate keys for protecting negotiations.

The IKE negotiation parameters determine:

- Which encryption algorithms may be applied for converting messages into a form that only the intended recipient can read
- Which authentication hash may be used for creating a keyed hash from a preshared or private key
- Which Diffie-Hellman group (DH Group) will be used to generate a secret session key

Phase 1 negotiations (in main mode or aggressive mode) begin as soon as a remote VPN peer or client attempts to establish a connection with the FortiGate unit. Initially, the remote peer or dialup client sends the FortiGate unit a list of potential cryptographic parameters along with a session ID. The FortiGate unit compares those parameters to its own list of advanced Phase 1 parameters and responds with its choice of matching parameters to use for authenticating and encrypting packets. The two peers handle the exchange of encryption keys between them, and authenticate the exchange through a preshared key or a digital signature.

Generating keys to authenticate an exchange

The FortiGate unit supports the generation of secret session keys automatically using a Diffie-Hellman algorithm. These algorithms are defined in [RFC 2409](#). The **Keylife** setting in the **Phase 1 Proposal** area determines the amount of time before the Phase 1 key expires. Phase 1 negotiations are re-keyed automatically when there is an active security association. See [Dead Peer Detection on page 1669](#).

You can enable or disable automatic re-keying between IKE peers through the `phase1-rekey` attribute of the `config system global` CLI command. For more information, see the “System” chapter of the [FortiGate CLI Reference](#).

When in FIPS-CC mode, the FortiGate unit requires DH key exchange to use values at least 3072 bits long. However most browsers need the key size set to 1024. You can set the minimum size of the DH keys in the CLI.

```
config system global
    set dh-params 3072
end
```

When you use a preshared key (shared secret) to set up two-party authentication, the remote VPN peer or client and the FortiGate unit must both be configured with the same preshared key. Each party uses a session key derived from the Diffie-Hellman exchange to create an authentication key, which is used to sign a known combination of inputs using an authentication algorithm (such as HMAC-MD5, HMAC-SHA-1, or HMAC-SHA-256). Hash-based Message Authentication Code (HMAC) is a method for calculating an authentication code

using a hash function plus a secret key, and is defined in [RFC 2104](#). Each party signs a different combination of inputs and the other party verifies that the same result can be computed.

For information regarding NP accelerated offloading of IPsec VPN authentication algorithms, please refer to the [Hardware Acceleration](#) handbook chapter.

When you use preshared keys to authenticate VPN peers or clients, you must distribute matching information to all VPN peers and/or clients whenever the preshared key changes.

As an alternative, the remote peer or dialup client and FortiGate unit can exchange digital signatures to validate each other's identity with respect to their public keys. In this case, the required digital certificates must be installed on the remote peer and on the FortiGate unit. By exchanging certificate DNs, the signed server certificate on one peer is validated by the presence of the root certificate installed on the other peer.

The following procedure assumes that you already have a Phase 1 definition that describes how remote VPN peers and clients will be authenticated when they attempt to connect to a local FortiGate unit. For information about the Local ID and XAuth options, see [Defining IKE negotiation parameters on page 1666](#) and [Defining IKE negotiation parameters on page 1666](#). Follow this procedure to add IKE negotiation parameters to the existing definition.

Defining IKE negotiation parameters

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Select **Phase 1 Proposal** and include the appropriate entries as follows:

Phase 1 Proposal

Select the encryption and authentication algorithms that will be used to generate keys for protecting negotiations.

Add or delete encryption and authentication algorithms as required. Select a minimum of one and a maximum of three combinations. The remote peer must be configured to use at least one of the proposals that you define.

It is invalid to set both **Encryption** and **Authentication** to null.

Encryption

Select a symmetric-key algorithms:

NULL — Do not use an encryption algorithm.

DES — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key.

3DES — Triple-DES; plain text is encrypted three times by three keys.

AES128 — A 128-bit block algorithm that uses a 128-bit key.

AES192 — A 128-bit block algorithm that uses a 192-bit key.

AES256 — A 128-bit block algorithm that uses a 256-bit key.

ChaCha20/Poly1305 — A 128-bit block algorithm that uses a 128-bit key and a symmetric cipher. Only available for IKEv2.

Authentication	<p>You can select either of the following message digests to check the authenticity of messages during an encrypted session:</p> <p>NULL — Do not use a message digest. MD5 — Message Digest 5. SHA1 — Secure Hash Algorithm 1 - a 160-bit message digest.</p> <p>To specify one combination only, set the Encryption and Authentication options of the second combination to NULL. To specify a third combination, use the Add button beside the fields for the second combination.</p> <p>For information regarding NP accelerated offloading of IPsec VPN authentication algorithms, please refer to the Hardware Acceleration handbook chapter.</p>
Diffie-Hellman Group	<p>Select one or more Diffie-Hellman groups from DH groups 1, 2, 5, 14 through 21, and 27 through 30. When using aggressive mode, DH groups cannot be negotiated. By default, DH group 14 is selected, to provide sufficient protection for stronger cipher suites that include AES and SHA2. If you select multiple DH groups, the order they appear in the configuration is the order in which they are negotiates.</p> <p>If both VPN peers (or a VPN server and its client) have static IP addresses and use aggressive mode, select a single DH group. The setting on the FortiGate unit must be identical to the setting on the remote peer or dialup client.</p> <p>When the remote VPN peer or client has a dynamic IP address and uses aggressive mode, select up to three DH groups on the FortiGate unit and one DH group on the remote peer or dialup client. The setting on the remote peer or dialup client must be identical to one of the selections on the FortiGate unit.</p> <p>If the VPN peer or client employs main mode, you can select multiple DH groups. At least one of the settings on the remote peer or dialup client must be identical to the selections on the FortiGate unit.</p>
Keylife	<p>Type the amount of time (in seconds) that will be allowed to pass before the IKE encryption key expires. When the key expires, a new key is generated without interrupting service. The keylife can be from 120 to 172800 seconds.</p>
Nat-traversal	<p>Enable this option if a NAT device exists between the local FortiGate unit and the VPN peer or client. The local FortiGate unit and the VPN peer or client must have the same NAT traversal setting (both selected or both cleared). When in doubt, enable NAT-traversal. See NAT traversal on page 1669.</p>

Keepalive Frequency	If you enabled NAT traversal, enter a keepalive frequency setting. The value represents an interval from 0 to 900 seconds where the connection will be maintained with no activity. For additional security this value must be as low as possible. See NAT keepalive frequency on page 1669 .
Dead Peer Detection	Enable this option to reestablish VPN tunnels on idle connections and clean up dead IKE peers if required. This feature minimizes the traffic required to check if a VPN peer is available or unavailable (dead). See Dead Peer Detection on page 1669 .

NAT traversal

Network Address Translation (NAT) is a way to convert private IP addresses to publicly routable Internet addresses and vice versa. When an IP packet passes through a NAT device, the source or destination address in the IP header is modified. FortiGate units support NAT version 1 (encapsulate on port 500 with non-IKE marker), version 3 (encapsulate on port 4500 with non-ESP marker), and compatible versions.

NAT cannot be performed on IPsec packets in ESP tunnel mode because the packets do not contain a port number. As a result, the packets cannot be demultiplexed. To work around this, the FortiGate unit provides a way to protect IPsec packet headers from NAT modifications. When the Nat-traversal option is enabled, outbound encrypted packets are wrapped inside a UDP IP header that contains a port number. This extra encapsulation allows NAT devices to change the port number without modifying the IPsec packet directly.

To provide the extra layer of encapsulation on IPsec packets, the Nat-traversal option must be enabled whenever a NAT device exists between two FortiGate VPN peers or a FortiGate unit and a dialup client such as FortiClient. On the receiving end, the FortiGate unit or FortiClient removes the extra layer of encapsulation before decrypting the packet.

Additionally, you can force IPsec to use NAT traversal. If NAT is set to **Forced**, the FortiGate will use a port value of zero when constructing the NAT discovery hash for the peer. This causes the peer to think it is behind a NAT device, and it will use UDP encapsulation for IPsec, even if no NAT is present. This approach maintains interoperability with any IPsec implementation that supports the NAT-T RFC.

NAT keepalive frequency

When a NAT device performs network address translation on a flow of packets, the NAT device determines how long the new address will remain valid if the flow of traffic stops (for example, the connected VPN peer may be idle). The device may reclaim and reuse a NAT address when a connection remains idle for too long.

To work around this, when you enable NAT traversal specify how often the FortiGate unit sends periodic keepalive packets through the NAT device in order to ensure that the NAT address mapping does not change during the lifetime of a session. To be effective, the keepalive interval must be smaller than the session lifetime value used by the NAT device.

The keepalive packet is a 138-byte ISAKMP exchange.

Dead Peer Detection

Sometimes, due to routing issues or other difficulties, the communication link between a FortiGate unit and a VPN peer or client may go down. Packets could be lost if the connection is left to time out on its own. The FortiGate unit provides a mechanism called Dead Peer Detection (DPD), sometimes referred to as gateway detection or ping server, to prevent this situation and reestablish IKE negotiations automatically before a

connection times out: the active Phase 1 security associations are caught and renegotiated (rekeyed) before the Phase 1 encryption key expires.

By default, Dead Peer Detection sends probe messages every five seconds by default (see `dpd-retryinterval` in the [FortiGate CLI Reference](#)). If you are experiencing high network traffic, you can experiment with increasing the ping interval. However longer intervals will require more traffic to detect dead peers which will result in more traffic.

In the web-based manager, the Dead Peer Detection option can be enabled when you define advanced Phase 1 options. The `config vpn ipsec phase1` CLI command supports additional options for specifying a retry count and a retry interval.

For more information about these commands and the related `config router gwdetect` CLI command, see the [FortiGate CLI Reference](#).

For example, enter the following CLI commands to configure dead peer detection on the existing IPsec Phase 1 configuration called `test` to use 15 second intervals and to wait for 3 missed attempts before declaring the peer dead and taking action.

```
config vpn ipsec phase1-interface
  edit <value>
    set dpd [disable | on-idle | on-demand]
    set dpd-retryinterval 15
    set dpd-retrycount 3
  next
end
```

The default for `vpn ipsec phase1 dpd` is `on-idle` when the type is `dynamic` to encourage dialup server configurations to more pro-actively delete tunnels if the peer goes away.

DPD scalability

On a dial-up server, if a multitude of VPN connections are idle, the increased DPD exchange could negatively impact the performance/load of the daemon. For this reason, an option is available in the CLI to send DPD passively in a mode called "on-demand".

- When there is no traffic and the last DPD-ACK had been received, IKE will not send DPDs periodically.
- IKE will only send out DPDs if there are outgoing packets to send but no inbound packets had since been received.

Syntax

Set DPD to `on-demand` to trigger DPD when IPsec traffic is sent but no reply is received from the peer.

```
config vpn ipsec phase1-interface
  edit <value>
    set dpd [disable | on-idle | on-demand]
  next
end
```

Certificate key size control

Proxy will choose the same SSL key size as the HTTPS server. If the key size from the server is 512, the proxy will choose 1024. If the key size is bigger than 1024, the proxy will choose 2048.

As a result, the `firewall ssl-ssh-profile` commands `certname-rsa`, `certname-dsa`, and `certname-ecdsa` have been replaced with more specific key size control commands under `vpn certificate` setting.

CLI syntax

```
config vpn certificate setting
  set certname-rsa1024 <name>
  set certname-rsa2048 <name>
  set certname-dsa1024 <name>
  set certname-dsa2048 <name>
  set certname-ecdsa256 <name>
  set certname-ecdsa384 <name>
end
```

Quantum resistant IKEv2 SA negotiation

An IKEv2 extension is available that changes the key generation mechanism to include a Post-quantum Pre-shared Key.

The addition of PPK in the calculation means that even if a quantum computer can break the Diffie-Hellman calculation to derive the DH-generated secret key, the inclusion of the PPK in the key generation algorithm means that the attacker is still unable to derive the keys used to authenticate the IKE SA negotiation (and so cannot impersonate either party in the negotiation) nor the keys used in negotiating an IPsec SA (or IKE SA).

Syntax

```
config vpn ipsec phase1-interface
  edit <name>
    set ike-version 2
    set type dynamic
    set ppk {disable | allow | require}
    set ppk-secret <ASCII string or hexadecimal encoded with a leading 0x>
    set ppk-identity <string>
  next
end
config user local
  edit <name>
    set type password
    set ppk-secret <ASCII string or hexadecimal encoded with a leading 0x>
  next
end
```

For troubleshooting, `diagnose vpn ike ga list` can indicate whether PPK was negotiated.

- The 'PPK' at the gateway level indicates whether PPK was negotiated during the initial IKE SA negotiation.
- The 'PPK' at the IKE SA level indicates whether PPK was negotiated on this IKE SA.
- The 'child' at the IKE SA level indicates whether the IKE SA is an initial IKE SA or whether it is a child IKE SA. The above has 'child: no' and so it is initial IKE SA.

Using XAuth authentication

Extended authentication (XAuth) increases security by requiring the remote dialup client user to authenticate in a separate exchange at the end of Phase 1. XAuth draws on existing FortiGate user group definitions and uses established authentication mechanisms such as PAP, CHAP, RADIUS, and LDAP to authenticate dialup clients. You can configure a FortiGate unit to function either as an XAuth server or an XAuth client. If the server or client is attempting a connection using XAuth and the other end is not using XAuth, the failed connection attempts that are logged will not specify XAuth as the reason.

Using the FortiGate unit as an XAuth server

A FortiGate unit can act as an XAuth server for dialup clients. When the Phase 1 negotiation completes, the FortiGate unit challenges the user for a user name and password. It then forwards the user's credentials to an external RADIUS or LDAP server for verification.

If the user records on the RADIUS server have suitably configured Framed-IP-Address fields, you can assign client virtual IP addresses by XAuth instead of from a DHCP address range. See [Assigning VIPs by RADIUS user group on page 1](#).

The authentication protocol to use for XAuth depends on the capabilities of the authentication server and the XAuth client:

- Select **PAP Server** whenever possible.
- You must select **PAP Server** for all implementations of LDAP and some implementations of Microsoft RADIUS.
- Select **Auto Server** when the authentication server supports **CHAP Server** but the XAuth client does not. The FortiGate unit will use PAP to communicate with the XAuth client and CHAP to communicate with the authentication server. You can also use **Auto Server** to allow multiple source interfaces to be defined in an IPsec/IKE policy

Before you begin, create user accounts and user groups to identify the dialup clients that need to access the network behind the FortiGate dialup server. If password protection will be provided through an external RADIUS or LDAP server, you must configure the FortiGate dialup server to forward authentication requests to the authentication server. For information about these topics, see the [FortiGate User Authentication Guide](#).

Authenticating a dialup user group using XAuth settings

1. At the FortiGate dialup server, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Select **Convert To Custom Tunnel**.
3. Edit **XAUTH**, select the **Type** setting, which determines the type of encryption method to use between the XAuth client, the FortiGate unit and the authentication server. Select one of the following options:
 - **Disabled** — Disables XAuth settings.
 - **PAP Server** — Password Authentication Protocol.
 - **CHAP Server** — Challenge-Handshake Authentication Protocol.
 - **Auto Server** — Use PAP between the XAuth client and the FortiGate unit, and CHAP between the FortiGate unit and the authentication server.
4. From the **User Group** list, select the user group that needs to access the private network behind the FortiGate unit. The group must be added to the FortiGate configuration before it can be selected here. For multiple user groups to be defined in the IPsec/IKE policy, select **Inherit from policy**.
4. Select **OK**.

5. Create as many policies as needed, specifying **Source User(s)** and **Destination Address**.
For example, one policy could have **user1** have access to **test_local_subnet_1**, while **user2** has access to **test_local_subnet_2**.

As of FortiOS 5.4.1, when XAuth settings are enabled, **Inherit from policy** is only available under **PAP Server** and **CHAP Server**, not **Auto Server**. Because of this, only one user group may be defined for **Auto Server**.

Using the FortiGate unit as an XAuth client

If the FortiGate unit acts as a dialup client, the remote peer, acting as an XAuth server, might require a username and password. You can configure the FortiGate unit as an XAuth client, with its own username and password, which it provides when challenged.

Configuring the FortiGate dialup client as an XAuth client

1. At the FortiGate dialup client, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Under **XAuth**, select **Enable as Client**.
4. In the **Username** field, type the FortiGate PAP, CHAP, RADIUS, or LDAP user name that the FortiGate XAuth server will compare to its records when the FortiGate XAuth client attempts to connect.
5. In the **Password** field, type the password to associate with the user name.
6. Select **OK**.

Dynamic IPsec route control

You can add a route to a peer destination selector by using the `add-route` option, which is available for all dynamic IPsec Phases 1 and 2, for both policy-based and route-based IPsec VPNs. This option was previously only available when `mode-cfg` was enabled in Phase 1.

The `add-route` option adds a route to the FortiGate unit's routing information base when the dynamic tunnel is negotiated. You can use the `distance` and `priority` options to set the distance and priority of this route. If this results in a route with the lowest distance, it is added to the FortiGate unit's forwarding information base.

You can also enable `add-route` in any policy-based or route-based Phase 2 configuration that is associated with a dynamic (dialup) Phase 1. In Phase 2, `add-route` can be enabled, disabled, or set to use the same route as Phase 1.

The `add-route` feature is enabled by default and is configured in the CLI.

Syntax

Phase 1

```
config vpn ipsec
  edit <name>
    set type dynamic
    set add-route {enable | disable}
  end
end
```

Phase 2

```
config vpn ipsec {phase2 | phase2-interface}
  edit <name>
    set add-route {phase1 | enable | disable}
  end
end
```

Blocking IPsec SA negotiation

For interface-based IPsec, IPsec SA negotiation blocking can only be removed if the peer offers a wildcard selector. If a wildcard selector is offered then the wildcard route will be added to the routing table with the distance/priority value configured in Phase 1 and, if that is the route with the lowest distance, it is installed into the forwarding information base.

In cases where this occurs, it is important to ensure that the distance value configured on Phase 1 is set appropriately.

Phase 2 parameters

This section describes the Phase 2 parameters that are required to establish communication through a VPN.

The following topics are included in this section:

Phase 2 settings

After IPsec VPN Phase 1 negotiations complete successfully, Phase 2 negotiation begins. Phase 2 parameters define the algorithms that the FortiGate unit can use to encrypt and transfer data for the remainder of the session. The basic Phase 2 settings associate IPsec Phase 2 parameters with a Phase 1 configuration.

When defining Phase 2 parameters, you can choose any set of Phase 1 parameters to set up a secure connection and authenticate the remote peer.

For more information on Phase 2 settings in the web-based manager, see [IPsec VPN in the web-based manager on page 1642](#).

The information and procedures in this section do not apply to VPN peers that perform negotiations using manual keys.

Phase 2 proposals

In Phase 2, the VPN peer or client and the FortiGate unit exchange keys again to establish a secure communication channel. The Phase 2 Proposal parameters select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of Security Associations (SAs). The keys are generated automatically using a Diffie-Hellman algorithm.

Replay detection

IPsec tunnels can be vulnerable to replay attacks. Replay Detection enables the FortiGate unit to check all IPsec packets to see if they have been received before. If any encrypted packets arrive out of order, the FortiGate unit discards them.

IKE/IPsec Extended Sequence Number (ESN) support

64-bit Extended Sequence numbers (as described in RFC 4303, RFC 4304 as an addition to IKEv1, and RFC 5996 for IKEv2.) are supported for IPsec when Replay Detection is enabled.

Perfect Forward Secrecy (PFS)

By default, Phase 2 keys are derived from the session key created in Phase 1. Perfect Forward Secrecy (PFS) forces a new Diffie-Hellman exchange when the tunnel starts and whenever the Phase 2 keylife expires, causing a new key to be generated each time. This exchange ensures that the keys created in Phase 2 are unrelated to the Phase 1 keys or any other keys generated automatically in Phase 2.

Keylife

The Keylife setting sets a limit on the length of time that a Phase 2 key can be used. The default units are seconds. Alternatively, you can set a limit on the number of kilobytes (KB) of processed data, or both. If you select

both, the key expires when either the time has passed or the number of KB have been processed. When the Phase 2 key expires, a new key is generated without interrupting service.

Quick mode selectors

Quick mode selectors determine which IP addresses can perform IKE negotiations to establish a tunnel. By only allowing authorized IP addresses access to the VPN tunnel, the network is more secure.

The default settings are as broad as possible: any IP address or configured address object, using any protocol, on any port.

While the drop down menus for specifying an address also show address groups, the use of address groups may not be supported on a remote endpoint device that is not a FortiGate.

The address groups are at the bottom of the list to make it easy to distinguish between addresses and address groups.

When configuring Quick Mode selector **Source address** and **Destination address**, valid options include IPv4 and IPv6 single addresses, IPv4 subnet, or IPv6 subnet. For more information on IPv6 IPsec VPN, see [Overview of IPv6 IPsec support on page 1](#).

There are some configurations that require specific selectors:

- The VPN peer is a third-party device that uses specific phase2 selectors.
- The FortiGate unit connects as a dialup client to another FortiGate unit, in which case (usually) you must specify a source IP address, IP address range, or subnet. However, this is not required if you are using dynamic routing and mode-cfg.

With FortiOS VPNs, your network has multiple layers of security, with quick mode selectors being an important line of defence.

- Routes guide traffic from one IP address to another.
- Phase 1 and Phase 2 connection settings ensure there is a valid remote end point for the VPN tunnel that agrees on the encryption and parameters.
- Quick mode selectors allow IKE negotiations only for allowed peers.
- Security policies control which IP addresses can connect to the VPN.
- Security policies also control what protocols are allowed over the VPN along with any bandwidth limiting.

FortiOS is limited with IKEv2 selector matching. When using IKEv2 with a named traffic selector, no more than 32 subnets per traffic selector are added, since FortiOS doesn't fully implement the IKEv2 selector matching rules.

The workaround is to use multiple Phase 2s. If the configuration is FGT <-> FGT, then the better alternative is to just use 0.0.0.0 <-> 0.0.0.0 and use the firewall policy for enforcement.

Using the add-route option

Consider using the `add-route` option to add a route to a peer destination selector. Phase 2 includes the option of allowing the `add-route` to automatically match the settings in Phase 1. For more information, refer to [Phase 1 parameters on page 1655](#).

Syntax

Phase 2

```
config vpn ipsec {phase2 | phase2-interface}
    edit <name>
        set add-route {phase1 | enable | disable}
    end
end
```

Configuring the Phase 2 parameters

If you are creating a hub-and-spoke configuration or an Internet-browsing configuration, you may have already started defining some of the required Phase 2 parameters. If so, edit the existing definition to complete the configuration.

Specifying the Phase 2 parameters

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Open the **Phase 2 Selectors** panel (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter a **Name** for the Phase 2 configuration, and select a **Phase 1** configuration from the drop-down list.
4. Select **Advanced**.
5. Include the appropriate entries as follows:

Phase 2 Proposal

Select the encryption and authentication algorithms that will be used to change data into encrypted code.

Add or delete encryption and authentication algorithms as required. Select a minimum of one and a maximum of three combinations. The remote peer must be configured to use at least one of the proposals that you define.

It is invalid to set both **Encryption** and **Authentication** to null.

Encryption

Select a symmetric-key algorithms:

NULL — Do not use an encryption algorithm.

DES — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key.

3DES — Triple-DES; plain text is encrypted three times by three keys.

AES128 — A 128-bit block algorithm that uses a 128-bit key.

AES192 — A 128-bit block algorithm that uses a 192-bit key.

AES256 — A 128-bit block algorithm that uses a 256-bit key.

ChaCha20/Poly1305 — A 128-bit block algorithm that uses a 128-bit key and a symmetric cipher. Only available for IKEv2.

Authentication	<p>You can select either of the following message digests to check the authenticity of messages during an encrypted session:</p> <p>NULL — Do not use a message digest. MD5 — Message Digest 5. SHA1 — Secure Hash Algorithm 1 - a 160-bit message digest.</p> <p>To specify one combination only, set the Encryption and Authentication options of the second combination to NULL. To specify a third combination, use the Add button beside the fields for the second combination.</p> <p>For information regarding NP accelerated offloading of IPsec VPN authentication algorithms, please refer to the Hardware Acceleration handbook chapter.</p>
Enable replay detection	Optionally enable or disable replay detection. Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel.
Enable perfect forward secrecy (PFS)	Enable or disable PFS. Perfect forward secrecy (PFS) improves security by forcing a new Diffie-Hellman exchange whenever keylife expires.
Diffie-Hellman Group	Select one Diffie-Hellman group (1, 2, 5, 14 through 21, or 27 through 30). The remote peer or dialup client must be configured to use the same group.
Keylife	Select the method for determining when the Phase 2 key expires: Seconds , KBytes , or Both . If you select Both , the key expires when either the time has passed or the number of KB have been processed. The range is from 120 to 172800 seconds, or from 5120 to 2147483648 KB.
Autokey Keep Alive	Enable the option if you want the tunnel to remain active when no data is being processed.
Auto-negotiate	Enable the option if you want the tunnel to be automatically renegotiated when the tunnel expires.
DHCP-IPsec	<p>Select Enable if the FortiGate unit acts as a dialup server and FortiGate DHCP server or relay will be used to assign VIP addresses to FortiClient dialup clients. The DHCP server or relay parameters must be configured separately.</p> <p>If the FortiGate unit acts as a dialup server and the FortiClient dialup client VIP addresses match the network behind the dialup server, select Enable to cause the FortiGate unit to act as a proxy for the dialup clients.</p> <p>This is available only for Phase 2 configurations associated with a dialup Phase 1 configuration. It works only on policy-based VPNs.</p>

Autokey Keep Alive

The Phase 2 SA has a fixed duration. If there is traffic on the VPN as the SA nears expiry, a new SA is negotiated and the VPN switches to the new SA without interruption. If there is no traffic, however, the SA expires (by default) and the VPN tunnel goes down. A new SA will not be generated until there is traffic.

The Autokey Keep Alive option ensures that a new Phase 2 SA is negotiated, even if there is no traffic, so that the VPN tunnel stays up.

Auto-negotiate

By default, the Phase 2 security association (SA) is not negotiated until a peer attempts to send data. The triggering packet and some subsequent packets are dropped until the SA is established. Applications normally resend this data, so there is no loss, but there might be a noticeable delay in response to the user.

If the tunnel goes down, the auto-negotiate feature (when enabled) attempts to re-establish the tunnel. Auto-negotiate initiates the Phase 2 SA negotiation automatically, repeating every five seconds until the SA is established.

Automatically establishing the SA can be important for a dialup peer. It ensures that the VPN tunnel is available for peers at the server end to initiate traffic to the dialup peer. Otherwise, the VPN tunnel does not exist until the dialup peer initiates traffic.

The auto-negotiate feature is available through the Command Line Interface (CLI) via the following commands:

```
config vpn ipsec phase2
  edit <phase2_name>
    set auto-negotiate enable
  end
```

Installing dynamic selectors via auto-negotiate

The IPsec SA connect message generated is used to install dynamic selectors. These selectors can now be installed via the auto-negotiate mechanism. When phase 2 has auto-negotiate enabled, and phase 1 has mesh-selector-type set to **subnet**, a new dynamic selector will be installed for each combination of source and destination subnets. Each dynamic selector will inherit the auto-negotiate option from the template selector and begin SA negotiation. Phase 2 selector sources from dial-up clients will all establish SAs without traffic being initiated from the client subnets to the hub.

DHCP-IPsec

Select this option if the FortiGate unit assigns VIP addresses to FortiClient dialup clients through a DHCP server or relay. This option is available only if the Remote Gateway in the Phase 1 configuration is set to Dialup User and it works only on policy-based VPNs.

With the DHCP-IPsec option, the FortiGate dialup server acts as a proxy for FortiClient dialup clients that have VIP addresses on the subnet of the private network behind the FortiGate unit. In this case, the FortiGate dialup server acts as a proxy on the local private network for the FortiClient dialup client. A host on the network behind the dialup server issues an ARP request, corresponding to the device MAC address of the FortiClient host (when a remote server sends an ARP to the local FortiClient dialup client). The FortiGate unit then answers the ARP request on behalf of the FortiClient host, and forwards the associated traffic to the FortiClient host through the tunnel.

Acting as a proxy prevents the VIP address assigned to the FortiClient dialup client from causing possible ARP broadcast problems — the normal and VIP addresses can confuse some network switches by two addresses having the same MAC address.

IPsec support for ChaCha20/Poly1305 AEAD cipher

In IKEv2, to support [RFC 7634](#), crypto algorithms ChaCha20 and Poly1305 can be used together as a combined mode AEAD cipher (like aes-gcm) in the new `crypto_ftnt cipher` in `cipher_chacha20poly1305.c`.

Syntax

```
config vpn ipsec phase2-interface
  edit <name>
    set phase1name <name>
    set proposal chacha20poly1305
  next
end
```

IPsec support for AES-GCM for IKEv2 Phase 1

In IKEv2, to support [RFC 5282](#), AEAD algorithm AES-GCM is now supported, both 128 and 256-bit variants.

Syntax

```
config vpn ipsec phase2-interface
  edit <name>
    set phase1name <name>
    set proposal [aes128gcm | aes256gcm]
  next
end
```

Defining VPN security policies

This section explains how to specify the source and destination IP addresses of traffic transmitted through an IPsec VPN, and how to define appropriate security policies.

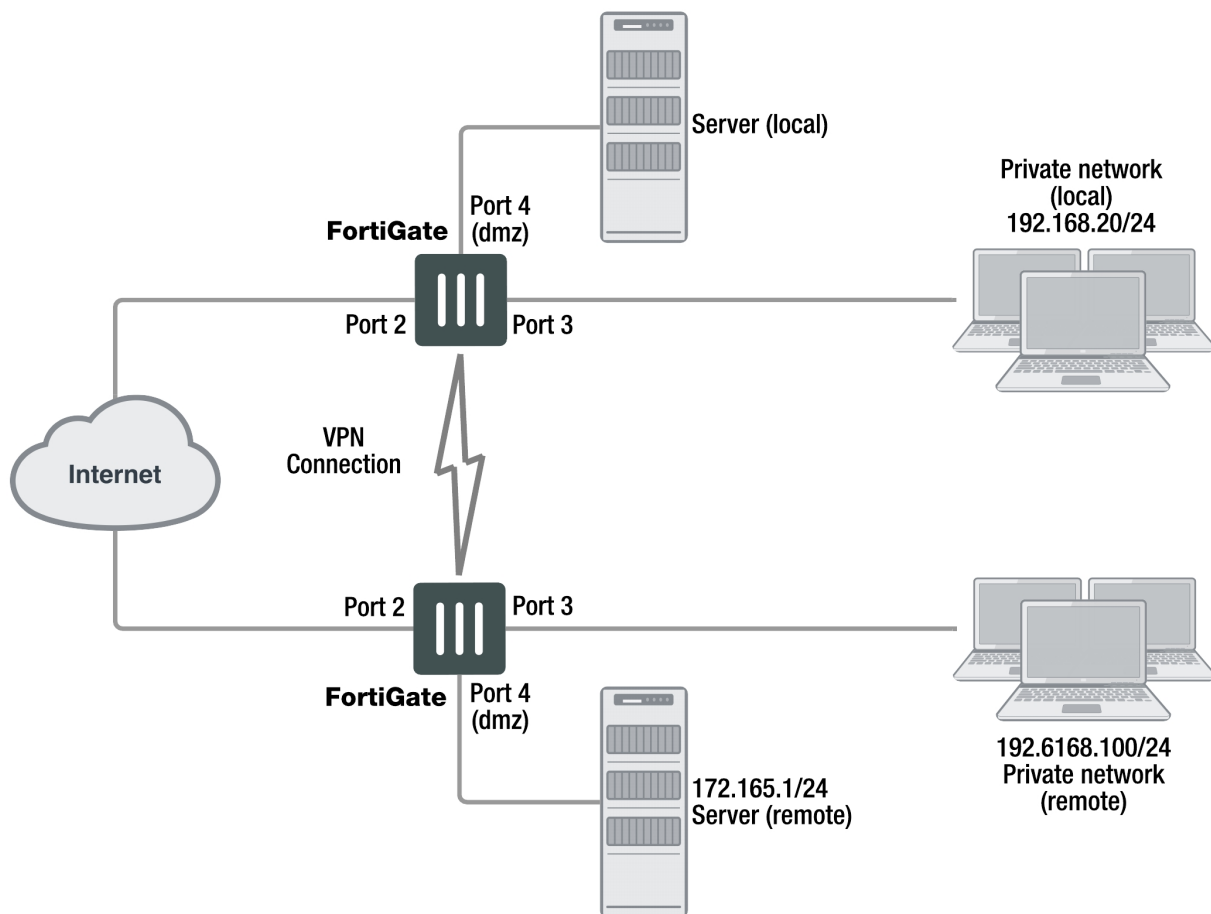

The following topics are included in this section:

Defining policy addresses

A VPN tunnel has two end points. These end points may be VPN peers such as two FortiGate gateways. Encrypted packets are transmitted between the end points. At each end of the VPN tunnel, a VPN peer intercepts encrypted packets, decrypts the packets, and forwards the decrypted IP packets to the intended destination.

You need to define firewall addresses for the private networks behind each peer. You will use these addresses as the source or destination address depending on the security policy.

Example topology for the following policies

In general:

- In a gateway-to-gateway, hub-and-spoke, dynamic DNS, redundant-tunnel, or transparent configuration, you need to define a policy address for the private IP address of the network behind the remote VPN peer (for example, 192.168.10.0/255.255.255.0 or 192.168.10.0/24).
- In a peer-to-peer configuration, you need to define a policy address for the private IP address of a server or host behind the remote VPN peer (for example, 172.16.5.1/255.255.255.255 or 172.16.5.1/32 or 172.16.5.1).

For a FortiGate dialup server in a dialup-client or Internet-browsing configuration:

- If you are not using VIP addresses, or if the FortiGate dialup server assigns VIP addresses to FortiClient dialup clients through FortiGate DHCP relay, select the predefined destination address “all” in the security policy to refer to the dialup clients.
- If you assign VIP addresses to FortiClient dialup clients manually, you need to define a policy address for the VIP address assigned to the dialup client (for example, 10.254.254.1/32), or a subnet address from which the VIP addresses are assigned (for example, 10.254.254.0/24 or 10.254.254.0/255.255.255.0).
- For a FortiGate dialup client in a dialup-client or Internet-browsing configuration, you need to define a policy address for the private IP address of a host, server, or network behind the FortiGate dialup server.

Defining a security IP address

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. In the **Name** field, type a descriptive name that represents the network, server(s), or host(s).
3. In **Type**, select **Subnet**.
4. In the **Subnet/IP Range** field, type the corresponding IP address and subnet mask.
For a subnet you could use the format 172.16.5.0/24 or its equivalent 172.16.5.0/255.255.255.0. For a server or host it would likely be 172.16.5.1/32. Alternately you can use an IP address range such as 192.168.10.[80-100] or 192.168.10.80-192.168.10.100.
5. Select **OK**.

Defining security policies for policy-based and route-based VPNs

Security policies allow IP traffic to pass between interfaces on a FortiGate unit. You can limit communication to particular traffic by specifying source address and destination addresses. Then only traffic from those addresses will be allowed.

Policy-based and route-based VPNs require different security policies.

- A policy-based VPN requires an IPsec security policy. You specify the interface to the private network, the interface to the remote peer and the VPN tunnel. A single policy can enable traffic inbound, outbound, or in both directions.
- A route-based VPN requires an Accept security policy for each direction. As source and destination interfaces, you specify the interface to the private network and the virtual IPsec interface (Phase 1 configuration) of the VPN. The IPsec interface is the destination interface for the outbound policy and the source interface for the inbound policy. One security policy must be configured for each direction of each VPN interface.

There are examples of security policies for both policy-based and route-based VPNs throughout this guide. See [Route-based or policy-based VPN on page 1725](#).

If the security policy, which grants the VPN Connection is limited to certain services, DHCP must be included, otherwise the client won't be able to retrieve a lease from the FortiGate's (IPsec) DHCP server, because the DHCP Request (coming out of the tunnel) will be blocked.

Policy-based VPN

An IPsec security policy enables the transmission and reception of encrypted packets, specifies the permitted direction of VPN traffic, and selects the VPN tunnel. In most cases, a single policy is needed to control both inbound and outbound IP traffic through a VPN tunnel. Be aware of the following considerations below before creating an IPsec security policy.

Allow traffic to be initiated from the remote site

Security policies specify which IP addresses can initiate a tunnel. By default, traffic from the local private network initiates the tunnel. When the **Allow traffic to be initiated from the remote site** option is selected, traffic from a dialup client, or a computer on a remote network, initiates the tunnel. Both can be enabled at the same time for bi-directional initiation of the tunnel.

Outbound and inbound NAT

When a FortiGate unit operates in NAT mode, you can also enable inbound or outbound NAT. Outbound NAT may be performed on outbound encrypted packets or IP packets in order to change their source address before they are sent through the tunnel. Inbound NAT is performed to intercept and decrypt emerging IP packets from the tunnel.

By default, these options are not selected in security policies and can only be set through the CLI. For more information on this, see the “config firewall” chapter of the [FortiGate CLI Reference](#).

Source and destination addresses

Most security policies control outbound IP traffic. A VPN outbound policy usually has a source address originating on the private network behind the local FortiGate unit, and a destination address belonging to a dialup VPN client or a network behind the remote VPN peer. The source address that you choose for the security policy identifies from where outbound cleartext IP packets may originate, and also defines the local IP address or addresses that a remote server or client will be allowed to access through the VPN tunnel. The destination address that you choose identifies where IP packets must be forwarded after they are decrypted at the far end of the tunnel, and determines the IP address or addresses that the local network will be able to access at the far end of the tunnel.

Enabling other policy features

You can fine-tune a policy for services such as HTTP, FTP, and POP3, enable logging, traffic shaping, antivirus protection, web filtering, email filtering, file transfer, email services, and optionally allow connections according to a predefined schedule.

As an option, differentiated services (diffserv or DSCP) for the security policy can be enabled through the CLI. For more information on this feature, see the [Traffic Shaping](#) handbook chapter, or the “firewall” chapter of the [FortiGate CLI Reference](#).

Before you begin

Before you define the IPsec policy, you must:

- Define the IP source and destination addresses. See [Defining policy addresses on page 1681](#).
- Specify the Phase 1 authentication parameters. See [Phase 1 parameters on page 1655](#).
- Specify the Phase 2 parameters. See [Phase 2 parameters on page 1675](#).

Defining an IPsec security policy

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New** and set the following options:

Name	Enter a name for the security policy.
Incoming Interface	Select the local interface to the internal (private) network.
Outgoing Interface	Select the local interface to the external (public) network.
Source	Select the name that corresponds to the local network, server(s), or host(s) from which IP packets may originate.
Destination Address	Select the name that corresponds to the remote network, server(s), or host(s) to which IP packets may be delivered.
Schedule	Keep the default setting (always) unless changes are needed to meet specific requirements.
Service	Keep the default setting (ANY) unless changes are needed to meet your specific requirements.
Action	For the purpose of this configuration, set Action to IPsec . Doing this will close Firewall / Network Options and open VPN Tunnel options. Select the VPN tunnel of your choice, and select Allow traffic to be initiated from the remote site , which will allow traffic from the remote network to initiate the tunnel.

3. You may enable UTM features, and/or event logging, or select advanced settings to authenticate a user group, or shape traffic. For more information, see the [Firewall](#) handbook chapter.
4. Select **OK**.
5. Place the policy in the policy list above any other policies having similar source and destination addresses.

Defining multiple IPsec policies for the same tunnel

You must define at least one IPsec policy for each VPN tunnel. If the same remote server or client requires access to more than one network behind a local FortiGate unit, the FortiGate unit must be configured with an IPsec policy for each network. Multiple policies may be required to configure redundant connections to a remote destination or control access to different services at different times.

To ensure a secure connection, the FortiGate unit must evaluate policies with **Action** set to **IPsec** before **ACCEPT** and **DENY**. Because the FortiGate unit reads policies starting at the top of the list, you must move all IPsec policies to the top of the list, and be sure to reorder your multiple IPsec policies that apply to the tunnel so that specific constraints can be evaluated before general constraints.

Adding multiple IPsec policies for the same VPN tunnel can cause conflicts if the policies specify similar source and destination addresses, but have different settings for the same service. When policies overlap in this manner, the system may apply the wrong IPsec policy or the tunnel may fail.

For example, if you create two equivalent IPsec policies for two different tunnels, it does not matter which one comes first in the list of IPsec policies — the system will select the correct policy based on the specified source and destination addresses. If you create two different IPsec policies for the same tunnel (that is, the two policies treat traffic differently depending on the nature of the connection request), you might have to reorder the IPsec policies to ensure that the system selects the correct IPsec policy.

Route-based VPN

When you define a route-based VPN, you create a virtual IPsec interface on the physical interface that connects to the remote peer. You create ordinary Accept security policies to enable traffic between the IPsec interface and the interface that connects to the private network. This makes configuration simpler than for policy-based VPNs, which require IPsec security policies.

Defining security policies for a route-based VPN

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New** and define an **ACCEPT** security policy to permit communication between the local private network and the private network behind the remote peer. Enter these settings in particular:

Name	Enter a name for the security policy.
Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the IPsec Interface you configured.
Source	Select the address name that you defined for the private network behind this FortiGate unit.
Destination Address	Select the address name that you defined for the private network behind the remote peer.
Action	Select ACCEPT .
NAT	Disable NAT .

To permit the remote client to initiate communication, you need to define a security policy for communication in that direction.

3. Select **Create New** and enter these settings in particular:

Name	Enter a name for the security policy.
Incoming Interface	Select the IPsec Interface you configured.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source	Select the address name that you defined for the private network behind the remote peer.

Destination Address	Select the address name that you defined for the private network behind this FortiGate unit.
Action	Select ACCEPT .
NAT	Disable NAT .

Gateway-to-gateway

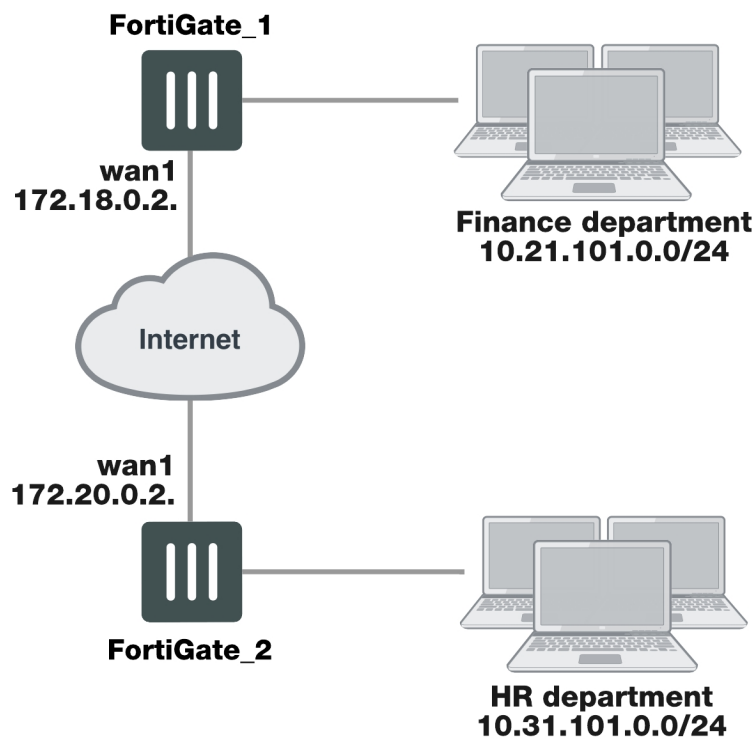

This section explains how to set up a basic gateway-to-gateway (site-to-site) IPsec VPN.

The following topics are included in this section:

Configuration overview

In a gateway-to-gateway configuration, two FortiGate units create a VPN tunnel between two separate private networks. All traffic between the two networks is encrypted and protected by FortiGate security policies.

Example gateway-to-gateway configuration

In some cases, computers on the private network behind one VPN peer may (by co-incidence) have IP addresses that are already used by computers on the network behind the other VPN peer. In this type of situation (ambiguous routing), conflicts may occur in one or both of the FortiGate routing tables and traffic destined for the remote network through the tunnel may not be sent. To resolve issues related to ambiguous routing, see [Configuration overview on page 1687](#).

In other cases, computers on the private network behind one VPN peer may obtain IP addresses from a local DHCP server. However, unless the local and remote networks use different private network address spaces, unintended ambiguous routing and/or IP-address overlap issues may arise. For a discussion of the related issues, see [FortiGate dialup-client configurations on page 1](#).

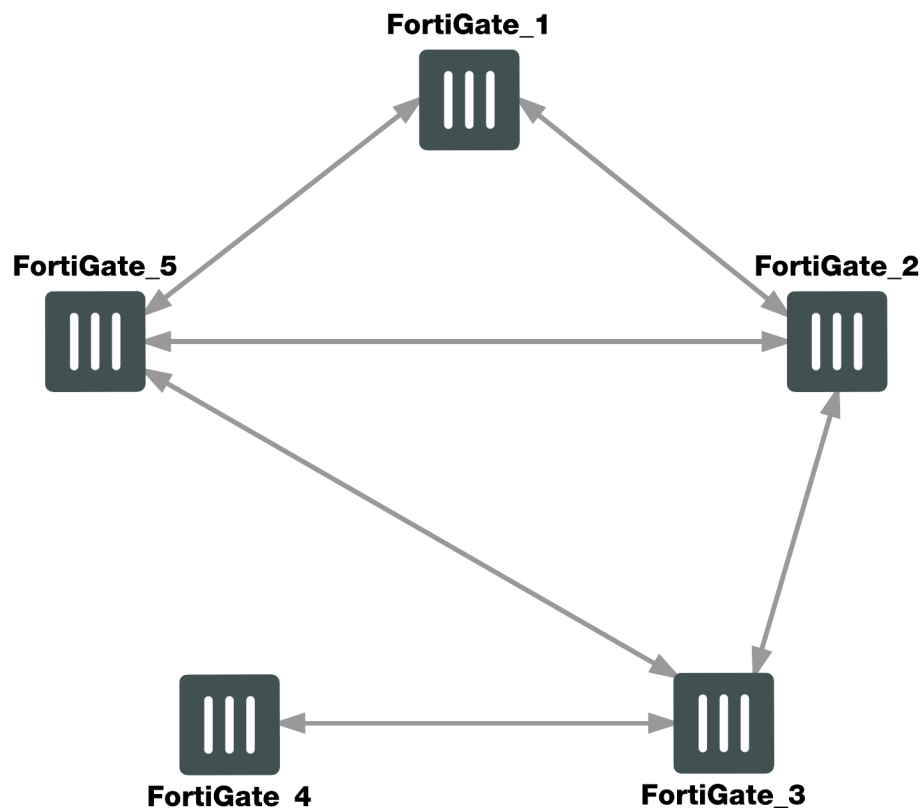

You can set up a fully meshed or partially meshed configuration (see below).

Fully meshed configuration

In a fully meshed network, all VPN peers are connected to each other, with one hop between peers. This topology is the most fault-tolerant: if one peer goes down, the rest of the network is not affected. This topology is difficult to scale because it requires connections between all peers. In addition, unnecessary communication can occur between peers. Best practices dictates a hub-and-spoke configuration instead (see [Hub-and-spoke configurations on page 1](#)).

Partially meshed configuration

A partially meshed network is similar to a fully meshed network, but instead of having tunnels between all peers, tunnels are only configured between peers that communicate with each other regularly.

Gateway-to-gateway configuration

The FortiGate units at both ends of the tunnel must be operating in NAT mode and have static public IP addresses.

When a FortiGate unit receives a connection request from a remote VPN peer, it uses IPsec Phase 1 parameters to establish a secure connection and authenticate that VPN peer. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec Phase 2 parameters and applies the IPsec security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

To support these functions, the following general configuration steps must be performed by both FortiGate units:

- Define the Phase 1 parameters that the FortiGate unit needs to authenticate the remote peer and establish a secure connection.
- Define the Phase 2 parameters that the FortiGate unit needs to create a VPN tunnel with the remote peer.
- Create security policies to control the permitted services and permitted direction of traffic between the IP source and destination addresses.

Configuring Phase 1 and Phase 2 for both peers

This procedure applies to both peers. Repeat the procedure on each FortiGate unit, using the correct IP address for each. You may wish to vary the Phase 1 names but this is optional. Otherwise all steps are the same for each peer.

The Phase 1 configuration defines the parameters that FortiGate_1 will use to authenticate FortiGate_2 and establish a secure connection. For the purposes of this example, a preshared key will be used to authenticate FortiGate_2. The same preshared key must be specified at both FortiGate units.

Before you define the Phase 1 parameters, you need to:

- Reserve a name for the remote gateway.
- Obtain the IP address of the public interface to the remote peer.
- Reserve a unique value for the preshared key.

The key must contain at least 6 printable characters and best practices dictate that it only be known by network administrators. For optimum protection against currently known attacks, the key must have a minimum of 16 randomly chosen alphanumeric characters.

At the local FortiGate unit, define the Phase 1 configuration needed to establish a secure connection with the remote peer. See [IPsec VPN in the web-based manager on page 1642](#).

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter the following information, and select **OK**.

Name	Enter <code>peer_1</code> . A name to identify the VPN tunnel. This name appears in Phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select Static IP Address .
IP Address	Enter <code>172.20.0.2</code> when configuring FortiGate_1. Enter <code>172.18.0.2</code> when configuring FortiGate_2. The IP address of the remote peer public interface.
Local Interface	Select wan1 .

The basic Phase 2 settings associate IPsec Phase 2 parameters with the Phase 1 configuration and specify the remote end point of the VPN tunnel. Before you define the Phase 2 parameters, you need to reserve a name for the tunnel. See [IPsec VPN in the web-based manager on page 1642](#).

1. Open the **Phase 2 Selectors** panel (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
2. Enter a **Name** of `peer_1_p2`.
3. Select **peer_1** from the **Phase 1** drop-down menu.

Creating security policies

Security policies control all IP traffic passing between a source address and a destination address.

An IPsec security policy is needed to allow the transmission of encrypted packets, specify the permitted direction of VPN traffic, and select the VPN tunnel that will be subject to the policy. A single policy is needed to control both inbound and outbound IP traffic through a VPN tunnel.

Before you define security policies, you must first specify the IP source and destination addresses. In a gateway-to-gateway configuration:

- The IP source address corresponds to the private network behind the local FortiGate unit.
- The IP destination address refers to the private network behind the remote VPN peer.

When you are creating security policies, choose one of either route-based or policy-based methods and follow it for both VPN peers. DO NOT configure both route-based and policy-based policies on the same FortiGate unit for the same VPN tunnel.

The configuration of FortiGate_2 is similar to that of FortiGate_1. You must:

- Define the Phase 1 parameters that FortiGate_2 needs to authenticate FortiGate_1 and establish a secure connection.
- Define the Phase 2 parameters that FortiGate_2 needs to create a VPN tunnel with FortiGate_1.
- Create the security policy and define the scope of permitted services between the IP source and destination addresses.

When creating security policies it is good practice to include a comment describing what the policy does.

Creating firewall addresses

Define names for the addresses or address ranges of the private networks that the VPN links. These addresses are used in the security policies that permit communication between the networks.

To define the IP address of the network behind FortiGate_1

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Enter the **Name** of `Finance_network`.
3. Select a **Type** of **Subnet**.
4. Enter the **Subnet** of `10.21.101.0/24`.
5. Select **OK**.

To specify the address of the network behind FortiGate_2

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Enter the **Name** of `HR_network`.
3. Select a **Type** of **Subnet**.
4. Enter the **Subnet/IP Range** of `10.31.101.0/24`.
5. Select **OK**.

Creating route-based VPN security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses.

To create route-based VPN security policies

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.

3. Enter the following, and select **OK**.

Incoming Interface	Select internal . The interface that connects to the private network behind this FortiGate unit.
Source Address	Select Finance_network when configuring FortiGate_1. Select HR_network when configuring FortiGate_2. The address name for the private network behind this FortiGate unit.
Outgoing Interface	Select peer_1 . The VPN Tunnel (IPsec Interface) you configured earlier.
Destination Address	Select HR_network when configuring FortiGate_1. Select Finance_network when configuring FortiGate_2. The address name that you defined for the private network behind the remote peer.
Action	Select ACCEPT .
Enable NAT	Disable.
Comments	Allow Internal to remote VPN network traffic.

4. Optionally, configure any additional features you may want, such as UTM or traffic shaping.
 5. Select **Create New** to create another policy for the other direction.
 6. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
 7. Enter the following information, and select **OK**.

Incoming Interface	Select peer_1 . The VPN Tunnel (IPsec Interface) you configured.
Source Address	Select HR_network when configuring FortiGate_1. Select Finance_Network when configuring FortiGate_2. The address name defined for the private network behind the remote peer.
Outgoing Interface	Select internal . The interface that connects to the private network behind this FortiGate unit.

Destination Address	Select Finance_Network when configuring FortiGate_1. Select HR_network when configuring FortiGate_2. The address name defined for the private network behind this FortiGate unit.
Action	Select ACCEPT .
Enable NAT	Disable.
Comments	Allow remote VPN network traffic to Internal.

8. Configure any additional features such as UTM or traffic shaping you may want. (optional).

All network traffic must have a static route to direct its traffic to the proper destination. Without a route, traffic will not flow even if the security policies are configured properly. You may need to create a static route entry for both directions of VPN traffic if your security policies allow bi-directional tunnel initiation.

To configure the route for a route-based VPN:

1. On FortiGate_2, go to **Network > Static Routes** and select **Create New**.
2. Enter the following information, and then select **OK**:

Destination IP / Mask	10.21.101.0/24
Device	FGT2_to_FGT1_Tunnel
Gateway	Leave as default: 0.0.0.0.
Distance (Advanced)	Leave this at its default. If there are other routes on this FortiGate unit, you may need to set the distance on this route so the VPN traffic will use it as the default route. However, this normally happens by default because this route is typically a better match than the generic default route.

Creating policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

1. Go to **Policy & Objects > IPv4 Policy**.
2. Complete the following:

Incoming Interface	Select internal . The interface that connects to the private network behind this FortiGate unit.
---------------------------	--

Source Address	Select Finance_network when configuring FortiGate_1. Select HR_network when configuring FortiGate_2. The address name defined for the private network behind this FortiGate unit.
Outgoing Interface	Select wan1 . The FortiGate unit's public interface.
Destination Address	Select HR_network when configuring FortiGate_1. Select Finance_network when configuring FortiGate_2.
VPN Tunnel	Select Use Existing and select peer_1 from the VPN Tunnel drop-down list. Select Allow traffic to be initiated from the remote site to enable traffic from the remote network to initiate the tunnel.
Comments	Bidirectional policy-based VPN policy.

Place VPN policies in the policy list above any other policies having similar source and destination addresses.

Remote Internet browsing for Site-to-Site VPN from the IPsec VPN Wizard

The IPsec VPN Wizard **Policy & Routing** section includes **Internet Access** options to support selecting **Share WAN** and **Force to use remote WAN**:

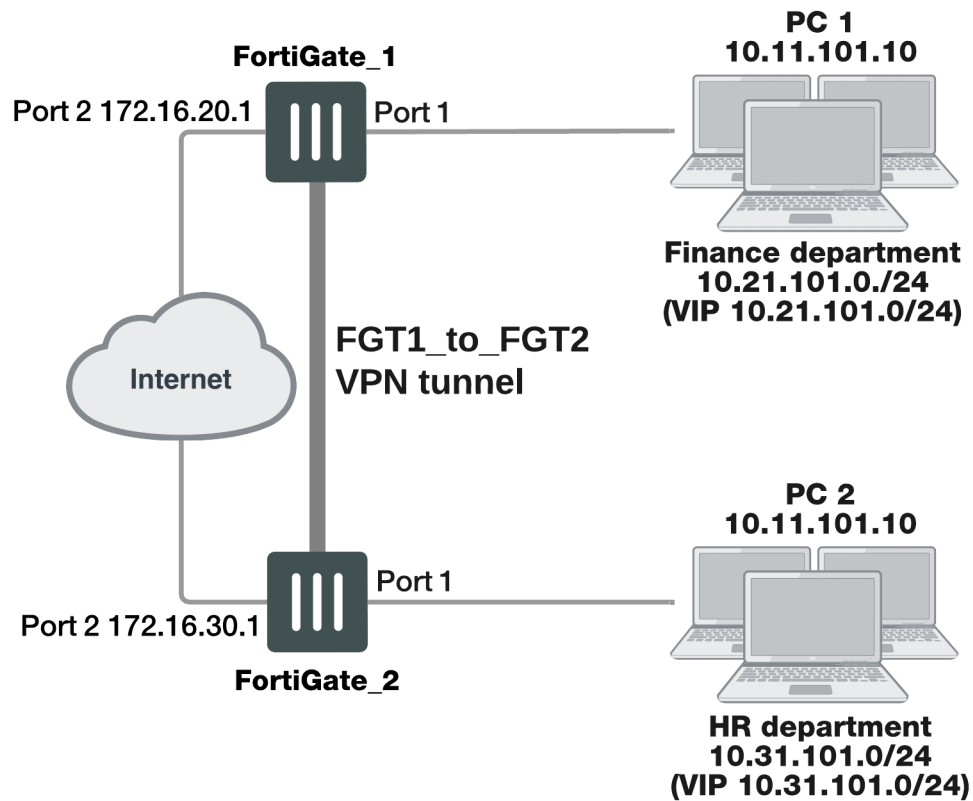

- The **Share WAN** option allows the remote subnet to browse the Internet via this FortiGate. When **Share WAN** is selected, a dropdown appears for the user to select the desired **Shared WAN**.
- The **Force to use remote WAN** option will send all Internet browsing traffic to the remote VPN gateway. The remote gateway must be configured with the **Share WAN** option enabled. When **Force to use remote WAN** is selected, a **Local Gateway** field appears (since a static route needs to be created to reach the remote gateway, because all other addresses will be routed via the VPN tunnel).

How to work with overlapping subnets

A site-to-site VPN configuration sometimes has the problem that the private subnet addresses at each end are the same. You can resolve this problem by remapping the private addresses using virtual IP addresses (VIP).

VIPs allow computers on those overlapping private subnets to each have another set of IP addresses that can be used without confusion. The FortiGate unit maps the VIP addresses to the original addresses. This means if PC1 starts a session with PC2 at 10.31.101.10, FortiGate_2 directs that session to 10.11.101.10 — the actual IP address of PC2. The figure below demonstrates this — Finance network VIP is 10.21.101.0/24 and the HR network is 10.31.101.0/24.

Overlapped subnets example

Solution for route-based VPN

You need to:

- Configure IPsec Phase 1 and Phase 2 as you usually would for a route-based VPN. In this example, the resulting IPsec interface is named `FGT1_to_FGT2`.
- Configure virtual IP (VIP) mapping:
 - the 10.21.101.0/24 network mapped to the 10.11.101.0/24 network on FortiGate_1
 - the 10.31.101.0/24 network mapped to the 10.11.101.0/24 network on FortiGate_2
- Configure an outgoing security policy with ordinary source NAT on both FortiGates.
- Configure an incoming security policy with the VIP as the destination on both FortiGates.
- Configure a route to the remote private network over the IPsec interface on both FortiGates.

To configure VIP mapping on both FortiGates

1. Go to **Policy & Objects > Virtual IPs** and create a new **Virtual IP**.
2. Enter the following information, and select **OK**:

Name	Enter a name, for example, <code>my_vip</code> .
External Interface	Select <code>FGT1_to_FGT2</code> . The IPsec interface.

VIP Type	Depending on both FortiGates, select one of the following options: <ul style="list-style-type: none"> • IPv4: If both FortiGates use IPv4 (Static NAT). • IPv6: If both FortiGates use IPv6 (Static NAT). • NAT46: Maps the IPv4 address into an IPv6 prefix. • NAT64: Maps the IPv6 address into an IPv4 prefix.
External IP Address/Range	For the External IP Address field enter: <p>10.21.101.1 when configuring FortiGate_1, or 10.31.101.1 when configuring FortiGate_2.</p>
Mapped IP Address/Range	For the Mapped IP Address enter 10.11.101.1. For the Range enter 10.11.101.254.
Port Forwarding	Disable

3. Repeat this procedure on both FortiGate_1 and FortiGate_2.

To configure the outbound security policy on both FortiGates

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**:

Incoming Interface	Select Port 1 .
Outgoing Interface	Select FGT1_to_FGT2 . The IPsec interface.
Source	Select all .
Destination Address	Select all .
Action	Select ACCEPT
NAT	Enable NAT .

3. Repeat this procedure on both FortiGate_1 and FortiGate_2.

To configure the inbound security policy on both FortiGates

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and then select **OK**:

Incoming Interface	Select FGT1_to_FGT2 .
---------------------------	------------------------------

Outgoing Interface	Select Port 1 . The IPsec interface.
Source	Select all .
Destination Address	Select my-vip .
Action	Select ACCEPT
NAT	Disable NAT .

3. Repeat this procedure on both FortiGate_1 and FortiGate_2.

To configure the static route for both FortiGates

1. Go to **Network > Static Routes** and create a new **Route** (or **IPv6 Route** as necessary).
2. Enter the following information, and then select **OK**:

Destination	Enter a subnet of 10.31.101.0/24 when configuring FortiGate_1. Enter a subnet of 10.21.101.0/24 when configuring FortiGate_2.
Device	Select FGT1_to_FGT2 .
Gateway	Leave as default: 0.0.0.0.
Administrative Distance	Leave at default (10). If you have advanced routing on your network, you may have to change this value.
Advanced Options	If you have advanced routing on your network, enable Advanced Options and enter a Priority .

Solution for policy-based VPN

As with the route-based solution, users contact hosts at the other end of the VPN using an alternate subnet address. PC1 communicates with PC2 using IP address 10.31.101.10, and PC2 communicates with PC1 using IP address 10.21.101.10.

In this solution however, outbound NAT is used to translate the source address of packets from the 10.11.101.0/24 network to the alternate subnet address that hosts at the other end of the VPN use to reply. Inbound packets from the remote end have their destination addresses translated back to the 10.11.101.0/24 network.

For example, PC1 uses the destination address 10.31.101.10 to contact PC2. Outbound NAT on FortiGate_1 translates the PC1 source address to 10.21.101.10. At the FortiGate_2 end of the tunnel, the outbound NAT configuration translates the destination address to the actual PC2 address of 10.11.101.10. Similarly, PC2 replies to PC1 using destination address 10.21.101.10, with the PC2 source address translated to 10.31.101.10. PC1 and PC2 can communicate over the VPN even though they both have the same IP address.

You need to:

- Configure IPsec Phase 1 as you usually would for a policy-based VPN.
- Configure IPsec Phase 2 with the `use-natip disable` CLI option.
- Define a firewall address for the local private network, 10.11.101.0/24.
- Define a firewall address for the remote private network:
 - Define a firewall address for 10.31.101.0/24 on FortiGate_1
 - Define a firewall address for 10.21.101.0/24 on FortiGate_2
- Configure an outgoing IPsec security policy with outbound NAT to map 10.11.101.0/24 source addresses:
 - To the 10.21.101.0/24 network on FortiGate_1
 - To the 10.31.101.0/24 network on FortiGate_2

To configure IPsec Phase 2 - CLI

```
config vpn ipsec phase2
  edit "FGT1_FGT2_p2"
    set keepalive enable
    set pfs enable
    set phase1name FGT1_to_FGT2
    set proposal 3des-sha1 3des-md5
    set replay enable
    set use-natip disable
  end
```

In this example, your Phase 1 definition is named `FGT1_to_FGT2`. `use-natip` is set to `disable`, so you can specify the source selector using the **`src-addr-type`**, `src-start-ip / src-end-ip` or `src-subnet` keywords. This example leaves these keywords at their default values, which specify the subnet `0.0.0.0/0`.

The `pfs` keyword ensures that perfect forward secrecy (PFS) is used. This ensures that each Phase 2 key created is unrelated to any other keys in use.

To define the local private network firewall address

1. Go to **Policy & Objects > Addresses** and create a new **Address**.
2. Enter the following information and select **OK**.

Category	Set to Address .
Name	Enter <code>vpn-local</code> . A meaningful name for the local private network.
Type	Set to IP/Netmask .
Subnet / IP Range	10.11.101.0 255.255.255.0
Interface	Set to any .

To define the remote private network firewall address

1. Go to **Policy & Objects > Addresses** and create a new **Address**.
2. Enter the following information, and select **OK**:

Category	Set to Address .
----------	-------------------------

Name	Enter <code>vpn-remote</code> . A meaningful name for the remote private network.
Type	Set to IP/Netmask .
Subnet / IP Range	10.31.101.0 255.255.255.0 on FortiGate_1. 10.21.101.0 255.255.255.0 on FortiGate_2.
Interface	Any

To configure the IPsec security policy

In the CLI on FortiGate_1, enter the commands:

```
config firewall policy
  edit 1
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "vpn-local"
    set dstaddr "vpn-remote"
    set action ipsec
    set schedule "always"
    set service "ANY"
    set inbound enable
    set outbound enable
    set vpngateway "FGT1_to_FGT2"
    set natoutbound enable
    set natip 10.31.101.0 255.255.255.0
  end
```

Optionally, you can set everything except `natip` in the web-based manager and then use the CLI to set `natip`.

Enter the same commands on FortiGate_2, but set `natip` be 10.21.101.0 255.255.255.0.

Testing

The best testing is to look at the packets both as the VPN tunnel is negotiated, and when the tunnel is up.

Determining what the other end of the VPN tunnel is proposing

1. Start a terminal program such as PuTTY and set it to log all output.
When necessary refer to the logs to locate information when output is verbose.
2. Logon to the FortiGate unit using a `super_admin` account.
3. Enter the following CLI commands.
4. Display all the possible IKE error types and the number of times they have occurred:

```
diag vpn ike errors
```

5. Check for existing debug sessions:

```
diag debug info
```

If a debug session is running, to halt it enter:

```
diag debug disable
```

6. Confirm your proposal settings:

```
diag vpn ike config list
```

7. If your proposal settings do not match what you expect, make a change to it and save it to force an update in memory. If that fixes the problem, stop here.

8. List the current vpn filter:

```
diag vpn ike filter
```

9. If all fields are set to any, there are no filters set and all VPN IKE packets will be displayed in the debug output. If your system has only a few VPNs, skip setting the filter.
If your system has many VPN connections this will result in very verbose output and make it very difficult to locate the correct connection attempt.

10. Set the VPN filter to display only information from the destination IP address for example 10.10.10.10:

```
diag vpn ike log-filter dst-addr4 10.10.10.10
```

To add more filter options, enter them one per line as above. Other filter options are:

clear	erase the current filter
dst-addr6	the IPv6 destination address range to filter by
dst-port	the destination port range to filter by
interface	interface that IKE connection is negotiated over
list	display the current filter
name	the phase1 name to filter by
negate	negate the specified filter parameter
src-addr4	the IPv4 source address range to filter by
src-addr6	the IPv6 source address range to filter by
src-port	the source port range to filter by
vd	index of virtual domain. 0 matches all

11. Start debugging:

```
diag debug app ike 255  
diag debug enable
```

12. Have the remote end attempt a VPN connection.

If the remote end attempts the connection they become the initiator. This situation makes it easier to debug VPN tunnels because then you have the remote information and all of your local information. by initiate the connection, you will not see the other end's information.

13. If possible go to the web-based manager on your FortiGate unit, go to the VPN monitor and try to bring the tunnel up.
14. Stop the debug output:

```
diag debug disable
```

15. Go back through the output to determine what proposal information the initiator is using, and how it is different from your VPN P1 proposal settings.

Things to look for in the debug output of attempted VPN connections are shown below.

Important terms to look for in VPN debug output

initiator	Starts the VPN attempt, in the above procedure that is the remote end
responder	Answers the initiator's request
local ID	In aggressive mode, this is not encrypted
error no SA proposal chosen	There was no proposal match — there was no encryption-authentication pair in common, usually occurs after a long list of proposal attempts
R U THERE and R U THERE ack	dead peer detection (dpd), also known as dead gateway detection — after three failed attempts to contact the remote end it will be declared dead, no farther attempts will be made to contact it
negotiation result	lists the proposal settings that were agreed on
SA_life_soft and SA_life_hard	negotiating a new key, and the key life
R U THERE	If you see this, it means Phase 1 was successful
tunnel up	the negotiation was successful, the VPN tunnel is operational

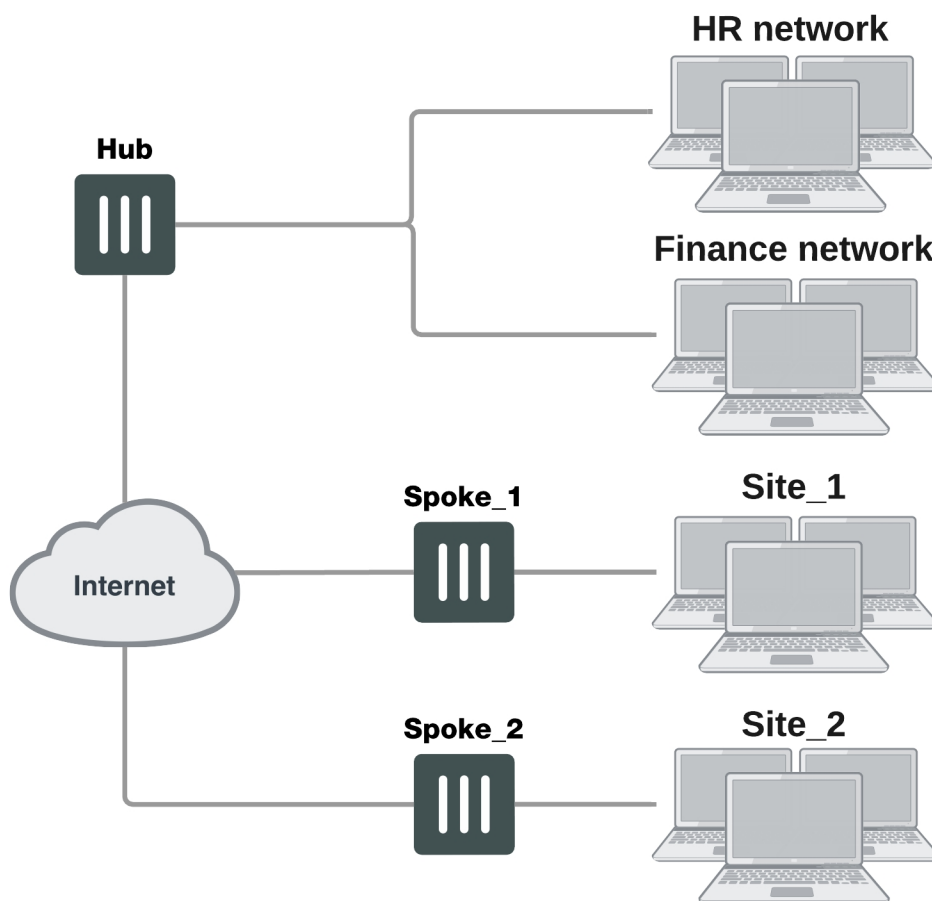

Hub-and-spoke configurations

This section describes how to set up hub-and-spoke IPsec VPNs. The following topics are included in this section:

Configuration overview

In a hub-and-spoke configuration, VPN connections radiate from a central FortiGate unit (the hub) to a number of remote peers (the spokes). Traffic can pass between private networks behind the hub and private networks behind the remote peers. Traffic can also pass between remote peer private networks through the hub.

Example hub-and-spoke configuration

The actual implementation varies in complexity depending on:

- Whether the spokes are statically or dynamically addressed
- The addressing scheme of the protected subnets
- How peers are authenticated

This guide discusses the issues involved in configuring a hub-and-spoke VPN and provides some basic configuration examples.

Hub-and-spoke infrastructure requirements

- The FortiGate hub must be operating in NAT mode and have a static public IP address.
- Spokes may have static IP addresses, dynamic IP addresses (see [FortiGate dialup-client configurations on page 1745](#)), or static domain names and dynamic IP addresses (see [Dynamic DNS configuration on page 1723](#)).

Spoke gateway addressing

The public IP address of the spoke is the VPN remote gateway as seen from the hub. Statically addressed spokes each require a separate VPN Phase 1 configuration on the hub. When there are many spokes, this becomes rather cumbersome.

Using dynamic addressing for spokes simplifies the VPN configuration because then the hub requires only a single Phase 1 configuration with “dialup user” as the remote gateway. You can use this configuration even if the remote peers have static IP addresses. A remote peer can establish a VPN connection regardless of its IP address if its traffic selectors match and it can authenticate to the hub. See [Configuration overview on page 1702](#) for an example of this configuration.

Protected networks addressing

The addresses of the protected networks are needed to configure destination selectors and sometimes for security policies and static routes. The larger the number of spokes, the more addresses there are to manage. You can

- Assign spoke subnets as part of a larger subnet, usually on a new network
- or
- Create address groups that contain all of the needed addresses

Using aggregated subnets

If you are creating a new network, where subnet IP addresses are not already assigned, you can simplify the VPN configuration by assigning spoke subnets that are part of a large subnet.

Aggregated subnets

All spokes use the large subnet address, 10.1.0.0/16 for example, as:

- The IPsec destination selector
- The destination of the security policy from the private subnet to the VPN (required for policy-based VPN, optional for route-based VPN)
- The destination of the static route to the VPN (route-based)

Each spoke uses the address of its own protected subnet as the IPsec source selector and as the source address in its VPN security policy. The remote gateway is the public IP address of the hub FortiGate unit.

Using an address group

If you want to create a hub-and-spoke VPN between existing private networks, the subnet addressing usually does not fit the aggregated subnet model discussed earlier. All of the spokes and the hub will need to include the addresses of all the protected networks in their configuration.

On FortiGate units, you can define a named firewall address for each of the remote protected networks and add these addresses to a firewall address group. For a policy-based VPN, you can then use this address group as the destination of the VPN security policy.

For a route-based VPN, the destination of the VPN security policy can be set to All. You need to specify appropriate routes for each of the remote subnets.

Authentication

Authentication is by a common pre-shared key or by certificates. For simplicity, the examples in this chapter assume that all spokes use the same pre-shared key.

Configure the hub

At the FortiGate unit that acts as the hub, you need to:

- Configure the VPN to each spoke
- Configure communication between spokes

You configure communication between spokes differently for a policy-based VPN than for a route-based VPN. For a policy-based VPN, you configure a VPN concentrator. For a route-based VPN, you must either define security policies or group the IPsec interfaces into a zone.

Define the hub-spoke VPNs

Perform these steps at the FortiGate unit that will act as the hub. Although this procedure assumes that the spokes are all FortiGate units, a spoke could also be VPN client software, such as FortiClient Endpoint Security.

Configuring the VPN hub

1. At the hub, define the Phase 1 configuration for each spoke. See [Phase 1 parameters on page 1655](#). Enter these settings in particular:

Name	Enter a name to identify the VPN in Phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	<p>The remote gateway is the other end of the VPN tunnel. There are three options:</p> <p>Static IP Address — Enter the spoke's public IP Address. You will need to create a Phase 1 configuration for each spoke. Either the hub or the spoke can establish the VPN connection.</p> <p>Dialup User — No additional information is needed. The hub accepts connections from peers with appropriate encryption and authentication settings. Only one Phase 1 configuration is needed for multiple dialup spokes. Only the spoke can establish the VPN tunnel.</p> <p>Dynamic DNS — If the spoke subscribes to a dynamic DNS service, enter the spoke's Dynamic DNS domain name. Either the hub or the spoke can establish the VPN connection. For more information, see Dynamic DNS configuration on page 1.</p>
Local Interface	Select the FortiGate interface that connects to the remote gateway. This is usually the FortiGate unit's public interface.

2. Define the Phase 2 parameters needed to create a VPN tunnel with each spoke. See [Phase 2 parameters on page 1675](#). Enter these settings in particular:

Name	Enter a name to identify this spoke Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined for this spoke.

IPsec VPN in ADVPN hub-and-spoke

IPsec VPN traffic is allowed through a tunnel between an ADVPN hub-and-spoke.

CLI syntax:

```
config vpn ipsec phase1-interface
edit "int-fgtb"
```

```

...
set auto-discovery-sender [enable | disable]
set auto-discovery-receiver [enable | disable]
set auto-discovery-forwarder [enable | disable]
...
next
end
config vpn ipsec phase2-interface
edit "int-fgtb"
...
set auto-discovery-sender phase1 [enable | disable]
...
next
end

```

Define the hub-spoke security policies

1. Define a name for the address of the private network behind the hub. For more information, see [Defining policy addresses on page 1](#).
2. Define names for the addresses or address ranges of the private networks behind the spokes. For more information, see [Defining policy addresses on page 1](#).
3. Define the VPN concentrator. See [To define the VPN concentrator on page 1707](#).
4. Define security policies to permit communication between the hub and the spokes. For more information, see [Defining VPN security policies on page 1](#).

Route-based VPN security policies

Define ACCEPT security policies to permit communications between the hub and the spoke. You need one policy for each direction.

Adding policies

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings in particular:

Incoming Interface	Select the VPN Tunnel (IPsec Interface) you configured in Step 1.
Source Address	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate unit.
Outgoing Interface	Select the hub's interface to the internal (private) network.
Destination Address	Select the source address that you defined in Step 1.
Action	Select ACCEPT .
Enable NAT	Enable.

Incoming Interface	Select the VPN Tunnel (IPsec Interface) you configured in Step 1.
---------------------------	---

Source Address	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate units.
Outgoing Interface	Select the source address that you defined in Step 1.
Destination Address	Select the hub's interface to the internal (private) network.
Action	Select ACCEPT .
Enable NAT	Enable.

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the hub and the spoke.

Adding policies

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the hub's interface to the internal (private) network.
Source Address	Select the source address that you defined in Step 1.
Outgoing Interface	Select the hub's public network interface.
Destination Address	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate unit.
VPN Tunnel	Select Use Existing and select the name of the Phase 1 configuration that you created for the spoke in Step 1. Select Allow traffic to be initiated from the remote site to enable traffic from the remote network to initiate the tunnel.

In the policy list, arrange the policies in the following order:

- IPsec policies that control traffic between the hub and the spokes first
- The default security policy last

Configuring communication between spokes (policy-based VPN)

For a policy-based hub-and-spoke VPN, you define a concentrator to enable communication between the spokes.

To define the VPN concentrator

1. At the hub, go to **VPN > IPsec Concentrator** and select **Create New**.
2. In the **Concentrator Name** field, type a name to identify the concentrator.
3. From the **Available Tunnels** list, select a VPN tunnel and then select the right-pointing arrow.
4. Repeat Step 3 until all of the tunnels associated with the spokes are included in the concentrator.
5. Select **OK**.

Configuring communication between spokes (route-based VPN)

For a route-based hub-and-spoke VPN, there are several ways you can enable communication between the spokes:

- Put all of the IPsec interfaces into a zone and enable intra-zone traffic. This eliminates the need for any security policy for the VPN, but you cannot apply UTM features to scan the traffic for security threats.
- Put all of the IPsec interfaces into a zone and create a single zone-to-zone security policy
- Create a security policy for each pair of spokes that are allowed to communicate with each other. The number of policies required increases rapidly as the number of spokes increases.

Using a zone as a concentrator

A simple way to provide communication among all of the spokes is to create a zone and allow intra-zone communication. You cannot apply UTM features using this method.

1. Go to **Network > Interfaces**.
2. Select the down-arrow on the **Create New** button and select **Zone**.
3. In the **Zone Name** field, enter a name, such as `Our_VPN_zone`.
4. Clear **Block intra-zone traffic**.
5. In the **Interface Members** list, select the IPsec interfaces that are part of your VPN.
6. Select **OK**.

Using a zone with a policy as a concentrator

If you put all of the hub IPsec interfaces involved in the VPN into a zone, you can enable communication among all of the spokes and apply UTM features with just one security policy.

Creating a zone for the VPN

1. Go to **Network > Interfaces**.
2. Select the down-arrow on the **Create New** button and select **Zone**.
3. In the **Zone Name** field, enter a name, such as `Our_VPN_zone`.
4. Select **Block intra-zone traffic**.
5. In the **Interface Members** list, select the IPsec interfaces that are part of your VPN.
6. Select **OK**.

Creating a security policy for the zone

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the settings: and select **OK**.

Incoming Interface	Select the zone you created for your VPN.
Source Address	Select All .
Outgoing Interface	Select the zone you created for your VPN.

Destination Address	Select All .
Action	Select ACCEPT .
Enable NAT	Enable.

Using security policies as a concentrator

To enable communication between two spokes, you need to define an ACCEPT security policy for them. To allow either spoke to initiate communication, you must create a policy for each direction. This procedure describes a security policy for communication from Spoke 1 to Spoke 2. Others are similar.

1. Define names for the addresses or address ranges of the private networks behind each spoke. For more information, see [Defining policy addresses on page 1](#).
2. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
3. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
4. Enter the settings and select **OK**.

Incoming Interface	Select the IPsec interface that connects to Spoke 1.
Source Address	Select the address of the private network behind Spoke 1.
Outgoing Interface	Select the IPsec interface that connects to Spoke 2.
Destination Address	Select the address of the private network behind Spoke 2.
Action	Select ACCEPT .
Enable NAT	Enable.

Configure the spokes

Although this procedure assumes that the spokes are all FortiGate units, a spoke could also be VPN client software, such as FortiClient Endpoint Security.

Perform these steps at each FortiGate unit that will act as a spoke.

Creating the Phase 1 and phase_2 configurations

1. At the spoke, define the Phase 1 parameters that the spoke will use to establish a secure connection with the hub. See [Phase 1 parameters on page 1655](#). Enter these settings:

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the interface that connects to the hub.

2. Create the Phase 2 tunnel definition. See [Phase 2 parameters on page 1675](#). Select the set of Phase 1 parameters that you defined for the hub. You can select the name of the hub from the **Static IP Address** part of the list.

Configuring security policies for hub-to-spoke communication

1. Create an address for this spoke. See [Defining policy addresses on page 1](#). Enter the IP address and netmask of the private network behind the spoke.
2. Create an address to represent the hub. See [Defining policy addresses on page 1](#). Enter the IP address and netmask of the private network behind the hub.
3. Define the security policy to enable communication with the hub.

Route-based VPN security policy

Define two security policies to permit communications to and from the hub.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings:

Incoming Interface	Select the virtual IPsec interface you created.
Source Address	Select the hub address you defined in Step 1.
Outgoing Interface	Select the spoke's interface to the internal (private) network.
Destination Address	Select the spoke addresses you defined in Step 2.
Action	Select ACCEPT .
Enable NAT	Enable

Incoming Interface	Select the spoke's interface to the internal (private) network.
Source Address	Select the spoke address you defined in Step 1.
Outgoing Interface	Select the virtual IPsec interface you created.
Destination Address	Select the hub destination addresses you defined in Step 2.
Action	Select ACCEPT .
Enable NAT	Enable

Policy-based VPN security policy

Define an IPsec security policy to permit communications with the hub. See [Defining VPN security policies on page 1](#).

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the spoke's interface to the internal (private) network.
Source Address	Select the spoke address you defined in Step 1.

Outgoing Interface	Select the spoke's interface to the external (public) network.
Destination Address	Select the hub address you defined in Step 2.
VPN Tunnel	Select Use Existing and select the name of the Phase 1 configuration you defined. Select Allow traffic to be initiated from the remote site to enable traffic from the remote network to initiate the tunnel.

Configuring security policies for spoke-to-spoke communication

Each spoke requires security policies to enable communication with the other spokes. Instead of creating separate security policies for each spoke, you can create an address group that contains the addresses of the networks behind the other spokes. The security policy then applies to all of the spokes in the group.

1. Define destination addresses to represent the networks behind each of the other spokes. Add these addresses to an address group.
2. Define the security policy to enable communication between this spoke and the spokes in the address group you created.

Policy-based VPN security policy

Define an IPsec security policy to permit communications with the other spokes. See [Defining VPN security policies on page 1](#). Enter these settings in particular:

Route-based VPN security policy

Define two security policies to permit communications to and from the other spokes.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings in particular:

Incoming Interface	Select the virtual IPsec interface you created.
Source Address	Select the spoke address group you defined in Step " Configure the spokes " on page 1709.
Outgoing Interface	Select the spoke's interface to the internal (private) network.
Destination Address	Select this spoke's address name.
Action	Select ACCEPT .
Enable NAT	Enable

4. Select **Create New**, leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**, and enter these settings:

Incoming Interface	Select the spoke's interface to the internal (private) network.
---------------------------	---

Source Address	Select this spoke's address name.
Outgoing Interface	Select the virtual IPsec interface you created.
Destination Address	Select the spoke address group you defined in Step 1.
Action	Select ACCEPT .
Enable NAT	Enable

Policy-based VPN security policy

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following:

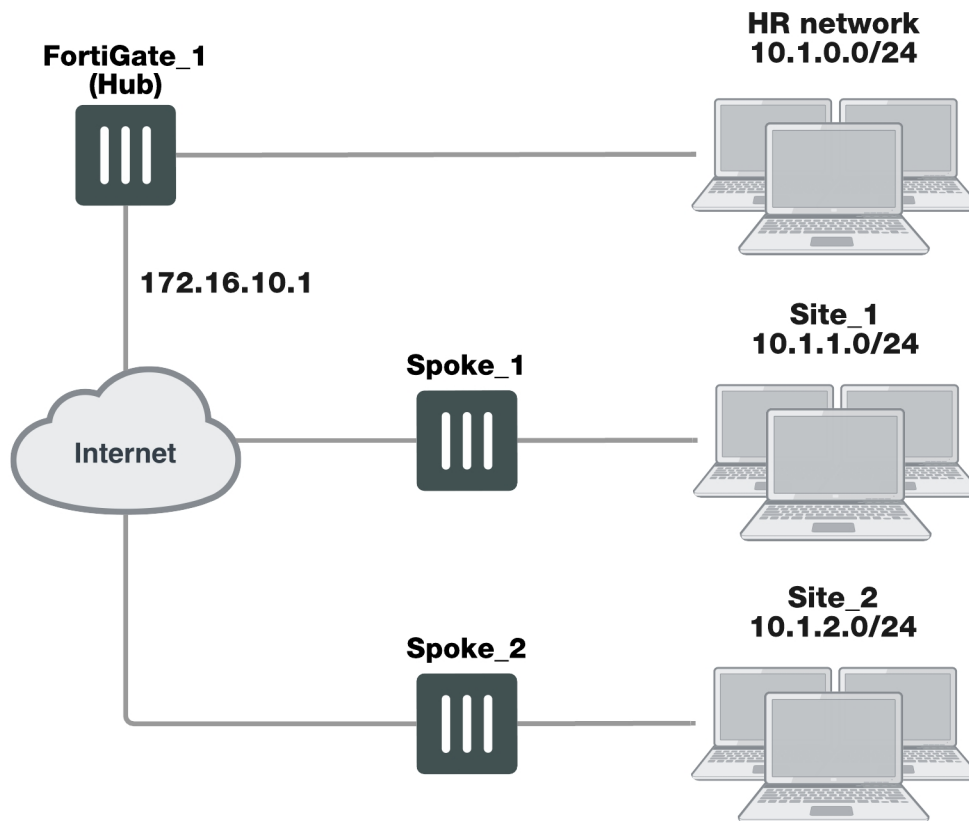

Incoming Interface	Select this spoke's internal (private) network interface.
Source Address	Select this spoke's source address.
Outgoing Interface	Select the spoke's interface to the external (public) network.
Destination Address	Select the spoke address group you defined in Step 1.
VPN Tunnel	<p>Select Use Existing and select the name of the Phase 1 configuration you defined.</p> <p>Select Allow traffic to be initiated from the remote site to enable traffic from the remote network to initiate the tunnel.</p>

Place this policy or policies in the policy list above any other policies having similar source and destination addresses.

Dynamic spokes configuration example

This example demonstrates how to set up a basic route-based hub-and-spoke IPsec VPN that uses preshared keys to authenticate VPN peers.

Example hub-and-spoke configuration

In the example configuration, the protected networks 10.1.0.0/24, 10.1.1.0/24 and 10.1.2.0/24 are all part of the larger subnet 10.1.0.0/16. The steps for setting up the example hub-and-spoke configuration create a VPN among Site 1, Site 2, and the HR Network.

The spokes are dialup. Their addresses are not part of the configuration on the hub, so only one spoke definition is required no matter the number of spokes. For simplicity, only two spokes are shown.

In an ADVPN topology, any two pair of peers can create a shortcut, as long as one of the devices is not behind NAT.

The on-the-wire format of the ADVPN messages use TLV encoding. Because of this, this feature is not compatible with any previous ADVPN builds.

Configure the hub (FortiGate_1)

The Phase 1 configuration defines the parameters that FortiGate_1 will use to authenticate spokes and establish secure connections.

For the purposes of this example, one preshared key will be used to authenticate all of the spokes. Each key must contain at least 6 printable characters and best practices dictates that it only be known by network administrators. For optimum protection against currently known attacks, each key must consist of a minimum of 16 randomly chosen alphanumeric characters.

Define the IPsec configuration

1. At FortiGate_1, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button). Define the Phase 1 parameters that the hub will use to establish a secure connection to the spokes.

Name	Enter a name (for example, <code>toSpokes</code>).
Remote Gateway	Dialup user
Local Interface	External
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID

The basic Phase 2 settings associate IPsec Phase 2 parameters with the Phase 1 configuration and specify the remote end points of the VPN tunnels.

3. Open the **Phase 2 Selectors** panel (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
4. Enter the following information, and select **OK**:

Name	Enter a name for the Phase 2 definition (for example, <code>toSpokes_ph2</code>).
Phase 1	Select the Phase 1 configuration that you defined previously (for example, <code>toSpokes</code>).

Define the security policies

security policies control all IP traffic passing between a source address and a destination address. For a route-based VPN, the policies are simpler than for a policy-based VPN. Instead of an IPSEC policy, you use an ACCEPT policy with the virtual IPsec interface as the external interface.

Before you define security policies, you must first define firewall addresses to use in those policies. You need addresses for:

- The HR network behind FortiGate_1
- The aggregate subnet address for the protected networks

Defining the IP address of the HR network behind FortiGate_1

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, enter the following information, and select **OK**:

Name	Enter an address name (for example, <code>HR_Network</code>).
-------------	--

Type	Subnet
Subnet/IP Range	Enter the IP address of the HR network behind FortiGate_1 (for example, 10.1.0.0/24).

Specifying the IP address the aggregate protected subnet

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, enter the following information, and select **OK**:

Address Name	Enter an address name (for example, Spoke_net).
Type	Subnet
Subnet/IP Range	Enter the IP address of the aggregate protected network, 10.1.0.0/16

Defining the security policy for traffic from the hub to the spokes

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**,
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information, and select **OK**:

Incoming Interface	Select the interface to the HR network, port 1 .
Source Address	Select HR_Network .
Outgoing Interface	Select the virtual IPsec interface that connects to the spokes, toSpokes .
Destination Address	Select Spoke_net .
Action	Select ACCEPT .

Place the policy in the policy list above any other policies having similar source and destination addresses.

Configure communication between spokes

Spokes communicate with each other through the hub. You need to configure the hub to allow this communication. An easy way to do this is to create a zone containing the virtual IPsec interfaces even if there is only one, and create a zone-to-zone security policy.

1. Go to **Network > Interfaces**.
2. Select the down-arrow on the **Create New** button and select **Zone**.
3. In the **Zone Name** field, enter a name, such as **Our_VPN_zone**.
4. Select **Block intra-zone traffic**.
You could enable intra-zone traffic and then you would not need to create a security policy. But, you would not be able to apply UTM features.
5. In **Interface Members**, select the virtual IPsec interface, **toSpokes**.
6. Select **OK**.

Creating a security policy for the zone

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings:

Incoming Interface	Select <code>Our_VPN_zone</code> .
Source Address	Select All .
Outgoing Interface	Select <code>Our_VPN_zone</code> .
Destination Address	Select All .
Action	Select ACCEPT .
Enable NAT	Enable.

4. Select **OK**.

Configure the spokes

In this example, all spokes have nearly identical configuration, requiring the following:

- Phase 1 authentication parameters to initiate a connection with the hub.
- Phase 2 tunnel creation parameters to establish a VPN tunnel with the hub.
- A source address that represents the network behind the spoke. This is the only part of the configuration that is different for each spoke.
- A destination address that represents the aggregate protected network.
- A security policy to enable communications between the spoke and the aggregate protected network

Define the IPsec configuration

At each spoke, create the following configuration.

1. At the spoke, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button). Enter the following information:

Name	Type a name, for example, <code>toHub</code> .
Remote Gateway	Select Static IP Address .
IP Address	Enter <code>172.16.10.1</code> .
Local Interface	Select Port2 .
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key. The value must be identical to the preshared key that you specified previously in the <code>FortiGate_1</code> configuration

Peer Options	Select Any peer ID .
---------------------	-----------------------------

1. Open the **Phase 2 Selectors** panel (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
2. Enter the following information and select **OK**:

Name	Enter a name for the tunnel, for example, <code>toHub_ph2</code> .
Phase 1	Select the name of the Phase 1 configuration that you defined previously, for example, <code>toHub</code> .
Advanced	Select to show the following Quick Mode Selector settings.
Source	Enter the address of the protected network at this spoke. For <code>spoke_1</code> , this is <code>10.1.1.0/24</code> . For <code>spoke_2</code> , this is <code>10.1.2.0/24</code> .
Destination	Enter the aggregate protected subnet address, <code>10.1.0.0/16</code> .

Define the security policies

You need to define firewall addresses for the spokes and the aggregate protected network and then create a security policy to enable communication between them.

Defining the IP address of the network behind the spoke

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New** and enter the following information:

Address Name	Enter an address name, for example <code>LocalNet</code> .
Type	Subnet
Subnet/IP Range	Enter the IP address of the private network behind the spoke. For <code>spoke_1</code> , this is <code>10.1.1.0/24</code> . For <code>spoke_2</code> , this is <code>10.1.2.0/24</code> .

Specifying the IP address of the aggregate protected network

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New** and enter the following information:

Address Name	Enter an address name, for example, <code>Spoke_net</code> .
Type	Subnet
Subnet/IP Range	Enter the IP address of the aggregate protected network, <code>10.1.0.0/16</code> .

Defining the security policy

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information:

Incoming Interface	Select the virtual IPsec interface, <code>toHub</code> .
Source Address	Select the aggregate protected network address <code>Spoke_net</code> .
Outgoing Interface	Select the interface to the internal (private) network, <code>port1</code> .
Destination Address	Select the address for this spoke's protected network <code>LocalNet</code> .
Action	Select ACCEPT .

4. Select **Create New**.
5. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
6. Enter the following information, and select **OK**:

Incoming Interface	Select the interface to the internal private network, <code>port1</code> .
Source Address	Select the address for this spoke's protected network, <code>LocalNet</code> .
Outgoing Interface	Select the virtual IPsec interface, <code>toHub</code> .
Destination Address	Select the aggregate protected network address, <code>Spoke_net</code> .
Action	Select ACCEPT .

Place these policies in the policy list above any other policies having similar source and destination addresses.

One-Click VPN (OCVPN)

One-Click VPN (OCVPN) is a cloud-based solution that greatly simplifies the provisioning and configuration of IPsec VPN. The administrator enables OCVPN with a single click, adds the required subnets, and then the configuration is complete. The OCVPN updates each FortiGate automatically as devices join/leave the VPN, as subnets are added/removed, when dynamic external IPs change (e.g. DHCP/PPPoE), and when WAN interface bindings change (as in the dual WAN redundancy case).

Configuration changes and events are automatically propagated across participating nodes without user intervention, so in a sense, the VPN manages itself as a unit with only bare minimum user input. The user specifies which subnets to participate in the VPN. Everything else happens transparently to the user.

After registering devices with FortiCare, devices use SSL to register local subnets with the OCVPN cloud service at <https://productapi.fortinet.com>. The WAN IP is determined automatically (devices must use a publicly routed external WAN IP address) and the gateway IP address and participating subnets are uploaded to a cloud repository that collects and stores the information in each customer's FortiCare account.

The following limitations apply to FortiOS OCVPN:

- The FortiGate must be registered with a valid FortiCare Support license.
- Only full-mesh VPN configurations using PSK cryptography are supported.
- Public IPs must be used (FortiGates behind NAT cannot participate).
- Non-root VDOMs and FortiGate VMs are not supported.
- Up to 16 nodes can be added to the OCVPN cloud, each with a maximum of 16 subnets.

OCVPN support for High Availability (HA)

As of 6.0.2, HA-enabled devices are now supported by OCVPN.

Prior to establishing the HA cluster, if OCVPN is in use then both devices should be registered to the OCVPN cloud service. During failover, the old serial number is withdrawn and a new serial number (and VPN) is added, to account for the change in status.

General configuration

If FortiCare Support is registered on the FortiGate, you can configure OCVPN in FortiOS under **VPN > One-Click VPN Settings**.

Once enabled, you can add the relevant **Subnets**, as well as view any **Cloud Members** currently participating in the cloud-serviced VPN (you may need to **Refresh** the **Cloud Members** table).

If you wish to change the polling interval, you must do so in the CLI Console (see below).

To enable and configure OCVPN - CLI:

```
config vpn ocvpn
  set status {enable | disable}
  set poll interval <30 - 120>
  config subnets
    edit 1
      set subnet 10.1.1.0 255.255.255.0
```

```

    next
    edit 2
        set subnet 10.1.2.0 255.255.255.0
    next
end
end

```

where:

Command	Description
<code>set status {enable disable}</code>	This command enables or disables the service. After a device has been registered with FortiCare, enabling this feature registers the device with the OCVPN cloud service. Disabling causes the device to be unregistered, and removed from the table of VPN members.
<code>poll interval <30 - 120></code>	Set the OCVPN polling interval. Enter an integer value from 30 to 120 (default = 60).
<code>config subnets</code>	This is the OCVPN subcommand for configuring the list of participating subnets.

Key exchange

Keys are generated automatically by OCVPN, but without explicit acknowledgment and state management, it would be impossible for the cloud to destroy keys after distribution to customer devices. Permanently storing customer keys in the cloud is undesirable for a host of reasons, so the RegAck request was introduced to effectively address the problem and allow the cloud to destroy keys after they have been installed. One key is generated per customer. When a new member joins, a new key is generated and distributed to all group members at the next poll interval (the default is 60 seconds).

Authentication is handled by SSL and proof of identity is established by the device serial number in the signed RSA certificate. The SN is sent in all messages to the cloud.

If you have a FortiWeb server performing authentication, the process is different. Since the OCVPN microservice doesn't run on the FortiWeb server, OCVPN authentication and secure segregation of customer data is handled as follows:

- FortiWeb extracts the ASN1 CN from the certificate and attaches it to the decrypted HTTP messages forwarded to OCVPN.
- OCVPN checks the presented device SN against the SN included in the certificate ID.
- If they don't match, OCVPN returns '401 Unauthorized' and the authentication transaction is cancelled.

Device polling and controller information

Instead of a central controller actively directing and pushing out the devices in response to network topology changes, FortiOS architecture uses device polling to propagate changes across nodes in the VPN. State changes are tracked carefully across the system so all devices always have the same view of the network (with some delay in propagating changes due to polling). Similarly the OCVPN cloud always know the state of each device. This is

essential to being able to manage the keys properly, and be able to discard them after they have been installed on each device.

The control layer is implemented on each device as a state machine, where information is translated from the member table into a working configuration—with IPsec phase1 and phase2 objects with default parameters, firewall address and address group objects, firewall policies, and static routes. The resulting configuration may be edited normally, e.g. DPD settings, DH group, crypto transform, firewall policy profiles for AV/IPS, etc. This is to provide a level of flexibility and usability.

The control layer's responsibility is to ensure that the network data on any device, and by extension the configuration, always stays in sync with the network view stored in the cloud, and in sync with all the other devices, regardless of intermittent network errors that could occur at any point in the system. The system is designed to handle network errors, changes, and events and keep the IPsec configuration consistently and reliable in sync.

Configuration information is managed in a fixed table: 16 nodes maximum, 16 subnets per node. After the table is populated, full mesh configuration is calculated and installed into the CMDB.

System states

The system is stateless across reboots. It re-registers after reboot, which re-initializes the state of the system. After bootup, the system is stateful across changes and polling interval queries/updates. The state file contains the hostname, current WAN ifname, current WAN IP, assigned slot, current state, previous state, current OCVPN table revision, last OCVPN response code (register/update), last polling response code, number of members, current member bitmask, previous member bitmask. The system uses this state information to track state changes locally and in the cloud.

Possible device states are:

```
enum cvpn_state {
    cvpn_st_none,
    cvpn_st_unregistered,
    cvpn_st_registering,
    cvpn_st_updating,
    cvpn_st_unregistering,
    cvpn_st_acknowledging,
    cvpn_st_registered
};
```

A normal sequence would be registering (updating) -> acknowledging -> registered.

Even though SSL/TCP is stateful and ensures delivery, the OCVPN microservice doesn't run on a FortiWeb SSL termination server. See ["Key exchange" on page 1720](#) for more info about how FortiWeb configuration differs. The explicit acknowledgment message (RegAck) ensures the OCVPN service knows when all nodes have received and applied the latest revision of the network information and key.

Debugging and logging

OCVPN debugging and logging is handled through a common API function. All debugs (except polling) are logged to /tmp/ocvpn/log. When the size of the log file exceeds 128k, the file is truncated and only the most recent 32k is saved.

The following diagnose commands may be useful when troubleshooting and debugging OCVPN configurations.

Command	Description
<code>diag vpn ocvpn</code>	Top level diagnose command for OCVPN.
<code>device-state</code>	Display OCVPN device state.
<code>log</code>	Display OCVPN log file from the device.
<code>status</code>	Display the current status of the device and last response code from the OCVPN service.
<code>print-members</code>	Print the OCVPN member table. This command accesses the OCVPN cloud service to retrieve the latest information, irrespective of the state of the device. It prints the raw JSON responses from OCVPN.

Dynamic DNS configuration

This section describes how to configure a site-to-site VPN, in which one FortiGate unit has a static IP address and the other FortiGate unit has a domain name and a dynamic IP address.

The following topics are included in this section:

Dynamic DNS over VPN concepts

A typical computer has a static IP address and one or more DNS servers to resolve fully qualified domain names (FQDN) into IP addresses. A domain name assigned to this computer is resolved by any DNS server having an entry for the domain name and its static IP address. The IP address never changes or changes only rarely so the DNS server can reliably say it has the correct address for that domain all the time.

Dynamic DNS (DDNS)

It is different when a computer has a dynamic IP address, such as an IP address assigned dynamically by a DHCP server, and a domain name. Computers that want to contact this computer do not know what its current IP address is. To solve this problem there are dynamic DNS (DDNS) servers. These are public servers that store a DNS entry for your computer that includes its current IP address and associated domain name. These entries are kept up to date by your computer sending its current IP address to the DDNS server to ensure its entry is always up to date. When other computers want to contact your domain, their DNS gets your IP address from your DDNS server. To use DDNS servers, you must subscribe to them and usually pay for their services.

When configuring DDNS on your FortiGate unit, go to **Network > DNS** and enable **Enable FortiGuard DDNS**. Then select the interface with the dynamic connection, which DDNS server you have an account with, your domain name, and account information. If your DDNS server is not on the list, there is a generic option where you can provide your DDNS server information.

Routing

When an interface has some form of changing IP address (DDNS, PPPoE, or DHCP assigned address), routing needs special attention. The standard static route cannot handle the changing IP address. The solution is to use the dynamic-gateway command in the CLI. Say for example you already have four static routes, and you have a PPPoE connection over the wan2 interface and you want to use that as your default route.

The route is configured on the dynamic address VPN peer trying to access the static address FortiGate unit.

Configuring dynamic gateway routing - CLI

```
config router static
  edit 5
    set dst 0.0.0.0 0.0.0.0
    set dynamic-gateway enable
    set device wan2
  next
end
```

For more information on DDNS, see the [System Administration](#) handbook chapter.

DDNS over VPN

IPsec VPN expects an IP address for each end of the VPN tunnel. All configuration and communication with that tunnel depends on the IP addresses as reference points. However, when the interface the tunnel is on has DDNS enabled there is no set IP address. The remote end of the VPN tunnel now needs another way to reference your end of the VPN tunnel. This is accomplished using Local ID.

A FortiGate unit that has a domain name and a dynamic IP address can initiate VPN connections anytime. The remote peer can reply to the local FortiGate unit using the source IP address that was sent in the packet header because it is current. Without doing a DNS lookup first, the remote peer runs the risk of the dynamic IP changing before it attempts to connect. To avoid this, the remote peer must perform a DNS lookup for the domain name of to be sure of the dynamic IP address before initiating the connection.

Remote gateway

When configuring the Phase 1 entry for a VPN tunnel, the Remote Gateway determines the addressing method the remote end of the tunnel uses as one of Static IP Address, Dialup User, or Dynamic DNS. There are different fields for each option.

When you select the Dynamic DNS VPN type there is a related field called Dynamic DNS. The Dynamic DNS field is asking for the FQDN of the remote end of the tunnel. It uses this information to look up the IP address of the remote end of the tunnel through the DDNS server associated with that domain name.

Local ID (peer ID)

The Local ID or peer ID can be used to uniquely identify one end of a VPN tunnel. This enables a more secure connection. Also if you have multiple VPN tunnels negotiating, this ensures the proper remote and local ends connect. When you configure it on your end, it is your Local ID. When the remote end connects to you, they see it as your peer ID.

If you are debugging a VPN connection, the Local ID is part of the VPN negotiations. You can use it to help troubleshoot connection problems.

In circumstances where multiple remote dialup VPN tunnels exist, each tunnel must have a peer ID set.

Configuring your Local ID

1. Go to **VPN > IPsec Wizard** and create the new custom tunnel or go to **VPN > IPsec Tunnels** and edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert To Custom Tunnel** button).
3. In the **Phase 1 Proposal** section, enter your **Local ID**.
4. Select **OK**.

The default configuration is to accept all local IDs (peer IDs). If you have **Local ID** set, the remote end of the tunnel must be configured to accept your local ID.

Accepting a specific Peer ID

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit **Authentication** (if it is not available, you may need to click the **Convert To Custom Tunnel** button).

3. Set **Mode** to **Aggressive**.
4. For **Peer Options**, select **This peer ID**. This option becomes visible only when **Aggressive** mode is selected.
5. In the **Peer ID** field, enter the string the other end of the tunnel used for its local ID.
6. Configure the rest of the Phase 1 entry as required.
7. Select **OK**.

Route-based or policy-based VPN

VPN over dynamic DNS can be configured with either route-based or policy-based VPN settings. Both are valid, but have differences in configuration. Choose the best method based on your requirements. For more information on route-based and policy-based, see [IPsec VPN overview on page 1638](#).

Route-based VPN configuration requires two security policies to be configured (one for each direction of traffic) to permit traffic over the VPN virtual interface, and you must also add a static route entry for that VPN interface or the VPN traffic will not reach its destination. See [Dynamic DNS configuration on page 1723](#) and [Dynamic DNS configuration on page 1723](#).

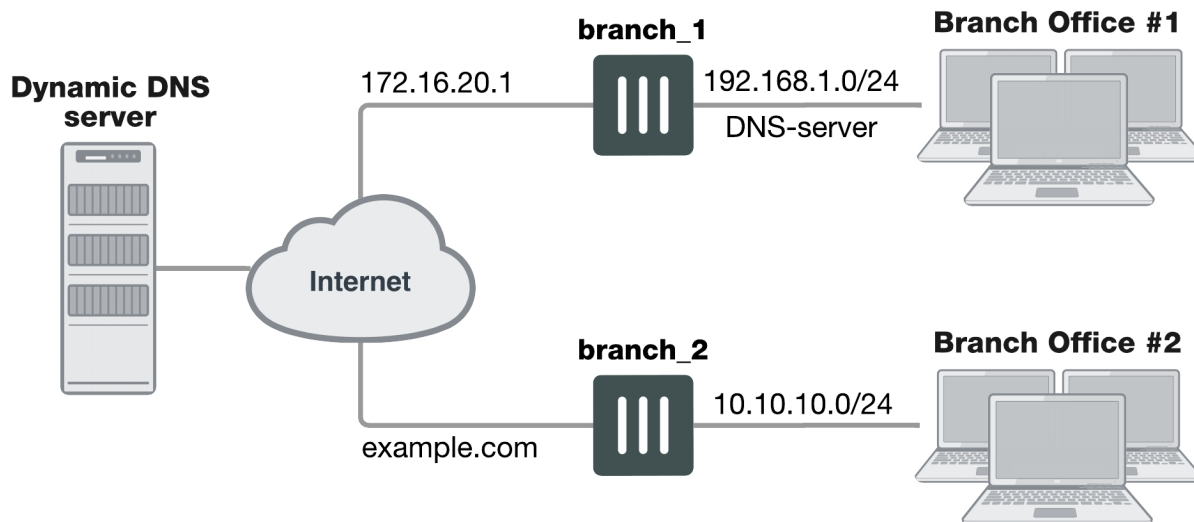

Policy-based VPN configuration uses more complex and often more IPsec security policies, but does not require a static route entry. It has the benefit of being able to configure multiple policies for handling multiple protocols in different ways, such as more scanning of less secure protocols or guaranteeing a minimum bandwidth for protocols such as VoIP. See [Dynamic DNS configuration on page 1723](#) and [Dynamic DNS configuration on page 1723](#).

DDNS topology

In this scenario, two branch offices each have a FortiGate unit and are connected in a gateway-to-gateway VPN configuration. One FortiGate unit has a domain name (example.com) with a dynamic IP address. See `branch_2` in the figure below.

Whenever the `branch_2` unit connects to the Internet (and possibly also at predefined intervals set by the ISP), the ISP may assign a different IP address to the FortiGate unit. The unit has its domain name registered with a dynamic DNS service. The `branch_2` unit checks in with the DDNS server on a regular basis, and that server provides the DNS information for the domain name, updating the IP address from time to time. Remote peers have to locate the `branch_2` FortiGate unit through a DNS lookup each time to ensure the address they get is current and correct.

Example dynamic DNS configuration

When a remote peer (such as the `branch_1` FortiGate unit above) initiates a connection to `example.com`, the local DNS server looks up and returns the IP address that matches the domain name `example.com`. The remote peer uses the retrieved IP address to establish a VPN connection with the `branch_2` FortiGate unit.

Assumptions

- You have administrator access to both FortiGate units.
- Both FortiGate units have interfaces named `wan1` and `internal`. (If not, you can use the alias feature to assign these labels as “nicknames” to other interfaces to follow this example.)
- Both FortiGate units have the most recent firmware installed, have been configured for their networks, and are currently passing normal network traffic.
- The `branch_2` FortiGate unit has its `wan1` interface defined as a dynamic DNS interface with the domain name of **example.com**.
- A basic gateway-to-gateway configuration is in place (see [Gateway-to-gateway configurations on page 1](#)) except one of the FortiGate units has a static domain name and a dynamic IP address instead of a static IP address.
- The FortiGate unit with the domain name is subscribed to one of the supported dynamic DNS services. Contact one of the services to set up an account. For more information and instructions about how to configure the FortiGate unit to push its dynamic IP address to a dynamic DNS server, see the [System Administration](#) handbook chapter.

Configuration overview

When a FortiGate unit receives a connection request from a remote VPN peer, it uses IPsec Phase 1 parameters to establish a secure connection and authenticate the VPN peer. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec Phase 2 parameters and applies the security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

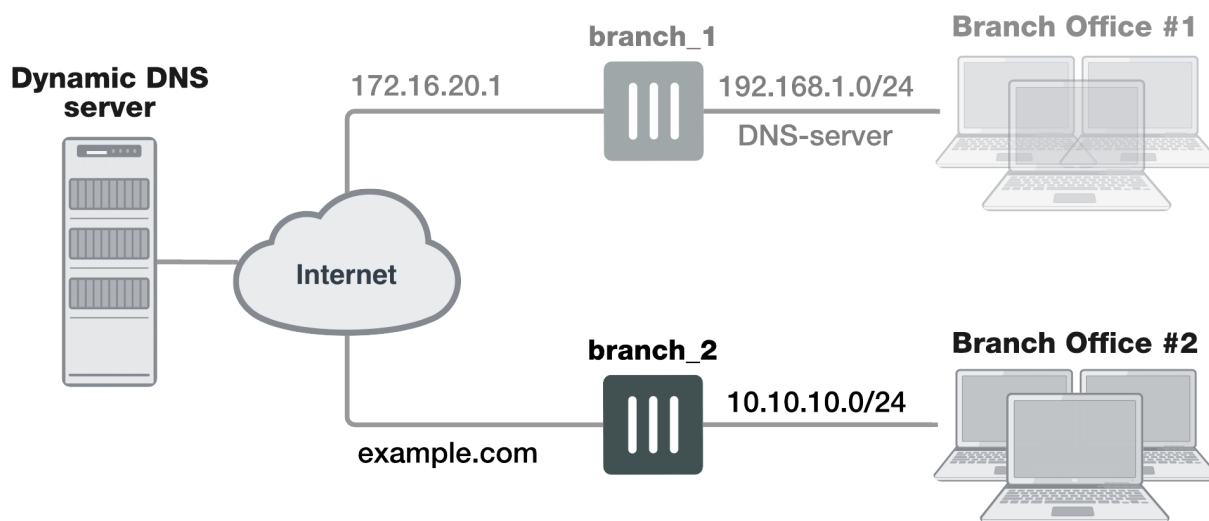

To support these functions, the following general configuration steps must be performed:

- Configure the branch_2 FortiGate unit with the dynamic IP address. This unit uses a Local ID string instead of an IP address to identify itself to the remote peer. See [Configuring the dynamically-addressed VPN peer](#) below, which is made up of configuring branch_2's VPN tunnel settings and security policies.
- Configure the fixed-address VPN peer. To initiate a VPN tunnel with the dynamically-addressed peer, this unit must first retrieve the IP address for the domain from the dynamic DNS service. See [Configuring the fixed-address VPN peer](#), which is made up of configuring branch_1's VPN tunnel settings and security policies.

Configuring the dynamically-addressed VPN peer

It is assumed that this FortiGate unit (branch_2) has already had its public facing interface, for example the wan1, configured with the proper dynamic DNS configuration.

Configuring branch_2, the dynamic address side

Define the Phase 1 parameters needed to establish a secure connection with the remote peer. See [Phase 1 parameters on page 1655](#). During this procedure you need to choose if you will be using route-based or policy-based VPNs.

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit **Network** (full configuration options are only available once you click the **Convert To Custom Tunnel** button).
3. Enter the following information:

Remote Gateway	<p>Select Static IP Address.</p> <p>The remote peer this FortiGate is connecting to has a static IP public address.</p> <p>If the remote interface is PPPoE do not select Retrieve default gateway from server.</p>
IP Address	Enter 172.16.20.1, the IP address of the public interface to the remote peer.

Interface	Select the Internet-facing interface wan1 (selected by default).
NAT Traversal	Select Enable (selected by default).
Keepalive Frequency	Enter a keepalive frequency (In seconds; set to 10 by default).
Dead Peer Detection	Select a dead peer detection option. On Idle will attempt to reestablish VPN tunnels when a connection becomes idle (the idle interval is not a negotiated value). Use of periodic dead peer detection incurs extra overhead. When communicating to large numbers of IKE peers, you should consider using On Demand . (set to On Demand by default).

4. Edit **Authentication** and complete the following:

Mode	Select Aggressive .
-------------	----------------------------

5. Edit **Phase 1 Proposal** and complete the following:

Local ID	Enter <code>example.com</code> . A character string used by the <code>branch_2</code> FortiGate unit to identify itself to the remote peer. This value must be identical to the value in the This peer ID field of the Phase 1 remote gateway configuration on the <code>branch_1</code> remote peer. See Configuration overview on page 1726 .
-----------------	--

6. Open the **Phase 2 Selectors** panel.
Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. For details on Phase 2, see [Phase 2 parameters on page 1675](#).
7. Enter the following information and select **OK**.

Name	Automatically entered as the name of the VPN tunnel.
Phase 1	Select <code>branch_2</code> . The name of the Phase 1 configuration that you defined earlier.

Define security policies to permit communications between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see [Defining VPN security policies on page 1](#).

After defining the two address ranges, select one of [Creating branch_2 route-based security policies on page 1729](#) or [Creating branch_2 policy-based security policies on page 1731](#) to configure the appropriate VPN policies.

Define VPN connection names for the address ranges of the private networks. These addresses are used in the security policies that permit communication between the networks. For more information, see [Defining VPN security policies on page 1](#).

Define an address name for the IP address and netmask of the private network behind the local FortiGate unit.

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**.
3. Enter the following information, and select **OK**.

Name	Enter <code>branch_2_internal</code> . Enter a meaningful name.
Type	Select IP/Netmask .
Subnet / IP Range	Enter <code>10.10.10.0/24</code> . Include the netmask or specify a specific range.
Interface	Select internal . The interface that will be handling the traffic from the internal network.

Define an address name for the IP address and netmask of the private network behind the remote peer.

4. Select **Create New**.
5. Enter the following information, and select **OK**.

Name	Enter <code>branch_1_internal</code> . A meaningful name for the private network at the remote end of the VPN tunnel.
Type	Select IP/Netmask .
Subnet / IP Range	Enter <code>192.168.1.0/24</code> . Include the netmask. Optionally you can specify a range
Interface	Select any . The interface that will be handling the remote VPN traffic on this FortiGate unit. If you are unsure, or multiple interfaces may be handling this traffic use <code>any</code> .

Creating branch_2 route-based security policies

Define ACCEPT security policies to permit communication between the branch_2 and branch_1 private networks. Once the route-based policy is configured a routing entry must be configured to route traffic over the VPN interface.

Define a policy to permit the branch_2 local FortiGate unit to initiate a VPN session with the branch_1 VPN peer.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	Enter an appropriate name for the policy.
-------------	---

Incoming Interface	Select internal . The interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select branch_2 . The VPN Tunnel (IPsec Interface).
Source	Select branch_2_internal . Select the address name for the private network behind this FortiGate unit.
Destination Address	Select branch_1_internal . The address name the private network behind the remote peer.
Action	Select ACCEPT .
NAT	Disable NAT .
Comments	Route-based: Initiate a branch_2 to branch_1 VPN tunnel.

Define a policy to permit the branch_1 remote VPN peer to initiate VPN sessions.

3. Select **Create New**.
4. Enter the following information, and select **OK**.

Name	Enter an appropriate name for the policy.
Incoming Interface	Select branch_2 . The VPN Tunnel (IPsec Interface).
Outgoing Interface	Select internal . The interface connecting the private network behind this FortiGate unit.
Source	Select branch_1_internal . The address name for the private network behind the remote peer.
Destination Address	Select branch_2_internal . The address name for the private network behind this FortiGate unit.
Action	Select ACCEPT .
NAT	Disable NAT .
Comments	Route-based: Initiate a branch_1 to branch_2 internal VPN tunnel.

5. Optionally configure any other security policy settings you require such as UTM or traffic shaping for this policy.
6. Place these policies in the policy list above any other policies having similar source and destination addresses. This will ensure VPN traffic is matched against the VPN policies before any other policies.

Creating routing entry for VPN interface - CLI

```
config router static
edit 5
set dst 0.0.0.0 0.0.0.0
```

```

        set dynamic-gateway enable
        set device wan1
    next
end

```

This routing entry must be added in the CLI because the dynamic-gateway option is not available in the web-based manager.

Creating branch_2 policy-based security policies

Define an IPsec policy to permit VPN sessions between the private networks. Define an IPsec policy to permit the VPN sessions between the local branch_2 unit and the remote branch_1 unit.

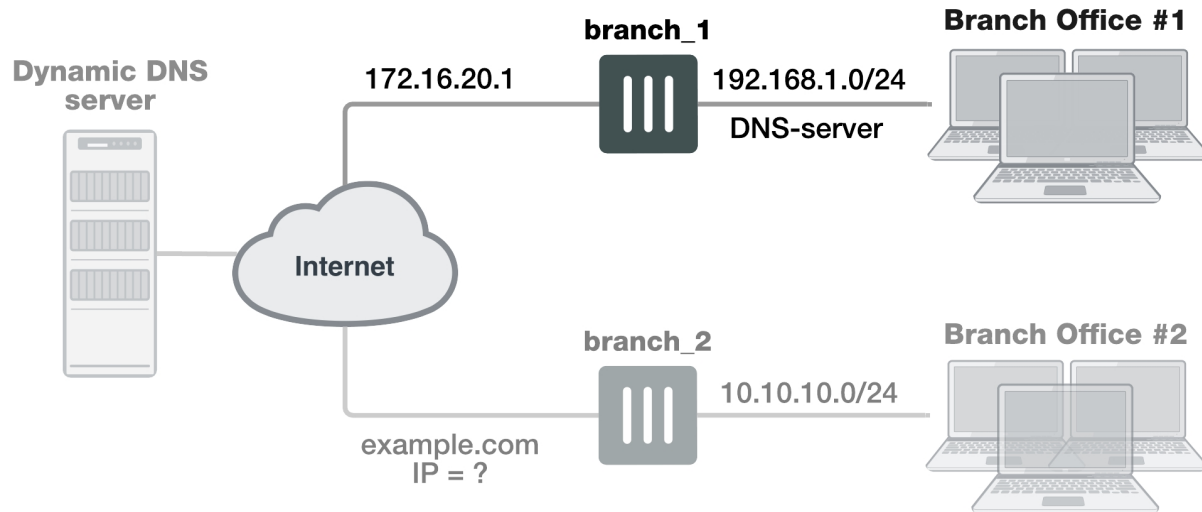

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	Enter an appropriate name for the policy.
Incoming Interface	Select internal . The interface connecting the private network behind this FortiGate unit.
Outgoing Interface	Select wan1 . The FortiGate unit's public interface.
Source	Select branch_2_internal . The address name for the private network behind this local FortiGate unit.
Destination Address	Select branch_1_internal . The address name for the private network behind branch_1, the remote peer.
Action	Select IPsec . Under VPN Tunnel , select branch_2 from the drop-down list. The name of the Phase 1 tunnel. Select Allow traffic to be initiated from the remote site .
Comments	Policy-based: allows traffic in either direction to initiate the VPN tunnel.

3. Optionally configure any other security policy settings you require such as UTM or traffic shaping for this policy.
4. Place these policies in the policy list above any other policies having similar source and destination addresses. This will ensure VPN traffic is matched against the VPN policies before any other policies.

Configuring the fixed-address VPN peer

The fixed-address VPN peer, branch_1, needs to retrieve the IP address from the dynamic DNS service to initiate communication with the dynamically-addressed peer, branch_2. It also depends on the peer ID (local ID) to initiate the VPN tunnel with branch_2.

Define the Phase 1 parameters needed to establish a secure connection with the remote peer. For more information, see [Phase 1 parameters on page 1655](#).

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit **Network** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter the following information and select **OK**.

Remote Gateway	Select Dynamic DNS . The remote peer this FortiGate is connecting to has a dynamic IP address.
Dynamic DNS	Type the fully qualified domain name of the remote peer (for example, <code>example.com</code>).
Interface	Select wan1 . The public facing interface on the fixed-address FortiGate unit.
Mode Config	Select Aggressive .
Peer Options	Select This peer ID , and enter <code>example.com</code> . This option only appears when the mode is set to Aggressive. The identifier of the FortiGate unit with the dynamic address.

4. Edit **Authentication**, enter the following information and select **OK**.

Peer Options	Select This peer ID , and enter <code>example.com</code> . This option only appears when the authentication method is set to Signature . The identifier of the FortiGate unit with the dynamic address.
---------------------	---

5. Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. See [Phase 2 parameters on page 1675](#). Enter these settings in particular:

Name	Enter <code>branch_1_p2</code> . A name to identify this Phase 2 configuration.
-------------	---

Phase 1Select **branch_1**.

The name of the Phase 1 configuration that you defined for the remote peer. You can select the name of the remote gateway from the Dynamic DNS part of the list.

The `branch_1` FortiGate unit has a fixed IP address and will be connecting to the `branch_2` FortiGate unit that has a dynamic IP address and a domain name of `example.com`. Remember if you are using route-based security policies that you must add a route for the VPN traffic.

Defining address ranges for branch_1 security policies

As with `branch_2` previously, `branch_1` needs address ranges defined as well. See [Defining policy addresses on page 1](#).

1. Go to **Policy & Objects > Addresses** and select **Create New > Address**.
2. Enter the following information, and select **OK**.

Name	Enter <code>branch_2_internal</code> . A meaningful name for the private network behind the <code>branch_2</code> FortiGate unit.
Type	Select IP/Netmask .
Subnet / IP Range	Enter <code>10.10.10.0/24</code> . Include the netmask or specify a specific range.
Interface	Select internal . This is the interface on this FortiGate unit that will be handling with this traffic.

3. Define an address name for the IP address and netmask of the private network behind the remote peer.
4. Create another address. Enter the following information, and select **OK**.

Name	Enter <code>branch_1_internal</code> . A meaningful name for the private network behind the <code>branch_1</code> peer.
Type	Select IP/Netmask .
Subnet / IP Range	Enter <code>192.168.1.0/24</code> . Include the netmask or specify a specific range.
Interface	Select any . The interface on this FortiGate unit that will be handling with this traffic. If you are unsure, or multiple interfaces may be handling this traffic use <code>any</code> .

Creating branch_1 route-based security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses. See [Defining VPN security policies on page 1](#).

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	Enter an appropriate name for the policy.
Incoming Interface	Select internal . The interface that connects to the private network behind the <code>branch_1</code> FortiGate unit.
Outgoing Interface	Select branch_1 . The VPN Tunnel (IPsec Interface) you configured earlier.
Source	Select branch_1_internal . The address name that you defined for the private network behind this FortiGate unit.
Destination Address	Select branch_2_internal . The address name that you defined for the private network behind the <code>branch_2</code> peer.
Action	Select ACCEPT .
NAT	Disable NAT .
Comments	Internal -> branch2

To permit the remote client to initiate communication, you need to define a security policy for communication in that direction.

3. Select **Create New**.
4. Enter the following information, and select **OK**.

Name	Enter an appropriate name for the policy.
Incoming Interface	Select branch_1 . The VPN Tunnel (IPsec Interface) you configured earlier.
Outgoing Interface	Select internal . The interface that connects to the private network behind this FortiGate unit.
Source	Select branch_2_internal . The address name that you defined for the private network behind the <code>branch_2</code> remote peer.
Destination Address	Select branch_1_internal . The address name that you defined for the private network behind this FortiGate unit.
Action	Select ACCEPT .
NAT	Disable NAT .
Comments	branch_2 -> Internal

Creating branch_1 policy-based security policies

A policy-based security policy allows you the flexibility to allow inbound or outbound traffic or both through this single policy.

This policy-based IPsec VPN security policy allows both inbound and outbound traffic

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**.

Incoming Interface	Select internal . The interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select wan1 . The FortiGate unit's public interface.
Source	Select branch_1_internal . The address name that you defined for the private network behind this FortiGate unit.
Destination Address	Select branch_2_internal . The address name that you defined for the private network behind the remote peer.
Action	Select IPsec . Under VPN Tunnel , select branch_1 from the drop-down list. The name of the Phase 1 tunnel. Select Allow traffic to be initiated from the remote site .

- Place this security policy in the policy list above any other policies having similar source and destination addresses.

Results

Once both ends are configured, you can test the VPN tunnel.

To test the VPN initiated by branch_2

- On branch_2, go to **Monitor > IPsec Monitor**.
All IPsec VPN tunnels will be listed on this page, no matter if they are connected or disconnected.
- Select the tunnel listed for branch_2, and select the status column for that entry.
The status will say **Bring Up** and remote port, incoming and outgoing data will all be zero. This indicates an inactive tunnel. When you right-click and select **Bring Up**, the FortiGate will try to set up a VPN session over this tunnel. If it is successful, Bring Up will change to Active, and the arrow icon will change to a green up arrow icon.
- If this does not create a VPN tunnel with increasing values for incoming and outgoing data, you need to start troubleshooting:

To test the VPN initiated by branch_1

- On branch_1, go to **Monitor > IPsec Monitor**.
- Select the tunnel listed for branch_1, and select the status column.
The difference between branch_2 and branch_1 at this point is that the tunnel entry for branch-1 will not have a remote gateway IP address. It will be resolved when the VPN tunnel is started.
- If this does not create a VPN tunnel with increasing values for incoming and outgoing data, you need to start troubleshooting.

Some troubleshooting ideas include:

- If there was no entry for the tunnel on the monitor page, check the Auto Key (IKE) page to verify the Phase 1 and Phase 2 entries exist.
- Check the security policy or policies, and ensure there is an outgoing policy as a minimum.
- Check that you entered a local ID in the Phase 1 configuration, and that branch_1 has the same local ID.
- Ensure the local DNS server has an up-to-date DNS entry for exmaple.com.

For more information, see [Troubleshooting on page 1](#).

FortiClient dialup-client configuration

The FortiClient Endpoint Security application is an IPsec VPN client with antivirus, antispam and firewall capabilities. This section explains how to configure dialup VPN connections between a FortiGate unit and one or more FortiClient Endpoint Security applications.

FortiClient users are usually mobile or remote users who need to connect to a private network behind a FortiGate unit. For example, the users might be employees who connect to the office network while traveling or from their homes.

For greatest ease of use, the FortiClient application can download the VPN settings from the FortiGate unit to configure itself automatically.

The following topics are included in this section:

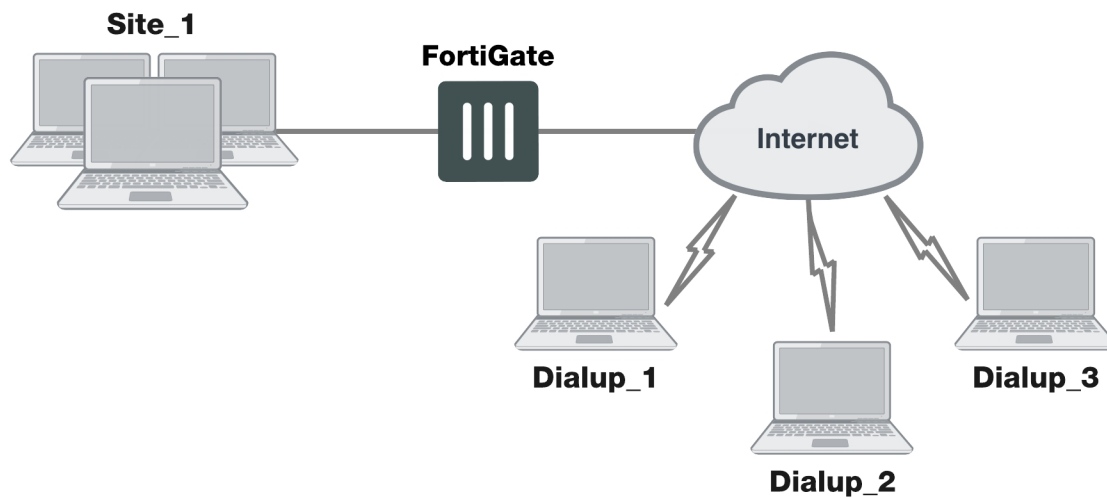

Configuration overview

Dialup users typically obtain dynamic IP addresses from an ISP through Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol over Ethernet (PPPoE). Then, the FortiClient Endpoint Security application initiates a connection to a FortiGate dialup server.

By default the FortiClient dialup client has the same IP address as the host PC on which it runs. If the host connects directly to the Internet, this is a public IP address. If the host is behind a NAT device, such as a router, the IP address is a private IP address. The NAT device must be NAT traversal (NAT-T) compatible to pass encrypted packets (see [Phase 1 parameters on page 1655](#)). The FortiClient application also can be configured to use a virtual IP address (VIP). For the duration of the connection, the FortiClient application and the FortiGate unit both use the VIP address as the IP address of the FortiClient dialup client.

The FortiClient application sends its encrypted packets to the VPN remote gateway, which is usually the public interface of the FortiGate unit. It also uses this interface to download VPN settings from the FortiGate unit. See [Automatic configuration of FortiClient dialup clients on page 1737](#).

Example FortiClient dialup-client configuration

Peer identification

The FortiClient application can establish an IPsec tunnel with a FortiGate unit configured to act as a dialup server. When the FortiGate unit acts as a dialup server, it does not identify the client using the Phase 1 remote gateway address. The IPsec tunnel is established if authentication is successful and the IPsec security policy associated with the tunnel permits access. If configured, the FortiGate unit could also require FortiClient registration, that is, the remote user would be required to have FortiClient installed before connection is completed.

Automatic configuration of FortiClient dialup clients

The FortiClient application can obtain its VPN settings from the FortiGate VPN server. FortiClient users need to know only the FortiGate VPN server IP address and their username and password on the FortiGate unit.

The FortiGate unit listens for VPN policy requests from clients on TCP port 8900. When the dialup client connects:

- The client initiates a Secure Sockets Layer (SSL) connection to the FortiGate unit.
- The FortiGate unit requests a user name and password from the FortiClient user. Using these credentials, it authenticates the client and determines which VPN policy applies to the client.
- Provided that authentication is successful, the FortiGate unit downloads a VPN policy to the client over the SSL connection. The information includes IPsec Phase 1 and Phase 2 settings, and the IP addresses of the private networks that the client is authorized to access.
- The client uses the VPN policy settings to establish an IPsec Phase 1 connection and Phase 2 tunnel with the FortiGate unit.

FortiClient-to-FortiGate VPN configuration steps

Configuring dialup client capability for FortiClient dialup clients involves the following general configuration steps:

1. If you will be using VIP addresses to identify dialup clients, determine which VIP addresses to use. As a precaution, consider using VIP addresses that are not commonly used.
2. Configure the FortiGate unit to act as a dialup server. See [Configure the FortiGate unit on page 1](#).

3. If the dialup clients will be configured to obtain VIP addresses through DHCP over IPsec, configure the FortiGate unit to act as a DHCP server or to relay DHCP requests to an external DHCP server.
4. Configure the dialup clients. See [Configure the FortiClient Endpoint Security application on page 1](#).

Using virtual IP addresses

When the FortiClient host PC is located behind a NAT device, unintended IP address overlap issues may arise between the private networks at the two ends of the tunnel. For example, the client's host might receive a private IP address from a DHCP server on its network that by co-incidence is the same as a private IP address on the network behind the FortiGate unit. A conflict will occur in the host's routing table and the FortiClient Endpoint Security application will be unable to send traffic through the tunnel. Configuring virtual IP (VIP) addresses for FortiClient applications prevents this problem.

Using VIPs ensures that client IP addresses are in a predictable range. You can then define security policies that allow access only to that source address range. If you do not use VIPs, the security policies must allow all source addresses because you cannot predict the IP address for a remote mobile user.

The FortiClient application must not have the same IP address as any host on the private network behind the FortiGate unit or any other connected FortiClient application. You can ensure this by reserving a range of IP addresses on the private network for FortiClient users. Or, you can assign FortiClient VIPs from an uncommonly used subnet such as 10.254.254.0/24 or 192.168.254.0/24.

You can reserve a VIP address for a particular client according to its device MAC address and type of connection. The DHCP server then always assigns the reserved VIP address to the client. For more information about this feature, see the "dhcp reserved-address" section in the "system" chapter of the [FortiGate CLI Reference](#).

On the host computer, you can find out the VIP address that the FortiClient Endpoint Security application is using. For example, in Windows command prompt, type `ipconfig /all`

On Linux or Mac OS X, type `ifconfig` in a terminal window. The output will also show the IP address that has been assigned to the host Network Interface Card (NIC).

It is best to assign VIPs using DHCP over IPsec. The FortiGate dialup server can act as a DHCP server or relay requests to an external DHCP server. You can also configure VIPs manually on FortiClient applications, but it is more difficult to ensure that all clients use unique addresses.

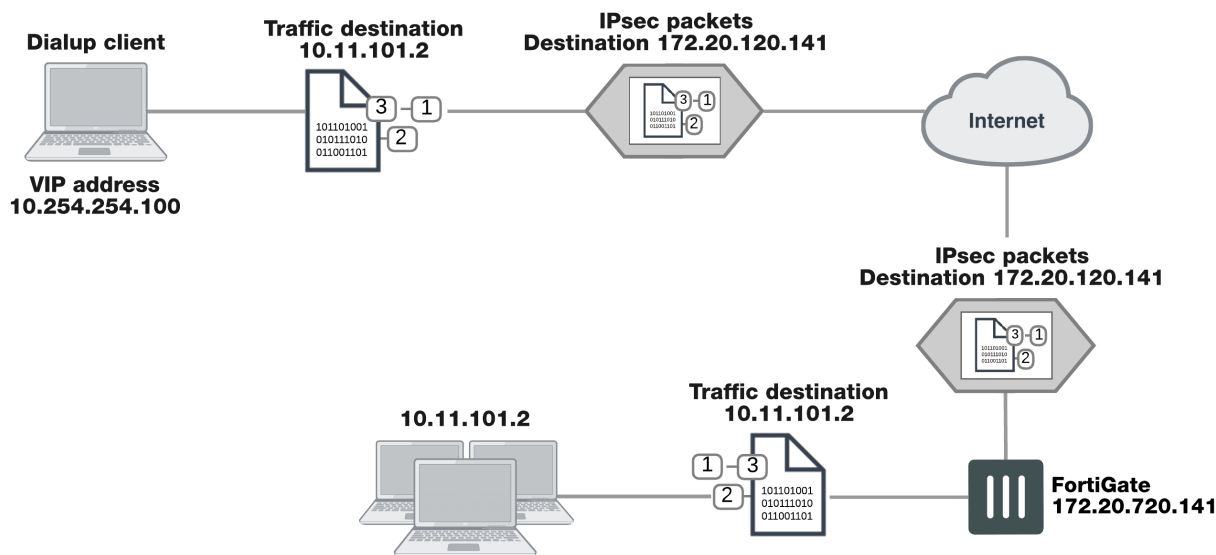

If you assign a VIP on the private network behind the FortiGate unit and enable DHCP-IPsec (a Phase 2 advanced option), the FortiGate unit acts as a proxy on the local private network for the FortiClient dialup client. Whenever a host on the network behind the dialup server issues an ARP request for the device MAC address of the FortiClient host, the FortiGate unit answers the ARP request on behalf of the FortiClient host and forwards the associated traffic to the FortiClient host through the tunnel. For more information, see [Phase 2 parameters on page 1675](#).

FortiGate units fully support [RFC 3456](#). The FortiGate DHCP over IPsec feature can be enabled to allocate VIP addresses to FortiClient dialup clients using a FortiGate DHCP server.

The figure below shows an example of a FortiClient-to-FortiGate VPN where the FortiClient application is assigned a VIP on an uncommonly used subnet. The diagram also shows that while the destination for the information in the encrypted packets is the private network behind the FortiGate unit, the destination of the IPsec packets themselves is the public interface of the FortiGate unit that acts as the end of the VPN tunnel.

IP address assignments in a FortiClient dialup-client configuration

Assigning VIPs by RADIUS user group

If you use XAuth authentication, you can assign users the virtual IP address stored in the Framed-IP-Address field of their record on the RADIUS server. (See [RFC 2865](#) and [RFC 2866](#) for more information about RADIUS fields.) To do this:

- Set the DHCP server **IP Assignment Mode** to **User-group defined method**. This is an Advanced setting. See [Configuring a DHCP server on a FortiGate interface on page 1743](#).
- Create a new firewall user group and add the RADIUS server to it.
- In your Phase 1 settings, configure the FortiGate unit as an XAuth server and select from **User Group** the new user group that you created. For more information, see [Phase 1 parameters on page 1655](#).
- Configure the FortiClient application to use XAuth. See [Configuration overview on page 1736](#).

FortiClient dialup-client infrastructure requirements

- To support policy-based VPNs, the FortiGate dialup server may operate in either NAT mode or transparent mode. NAT mode is required if you want to create a route-based VPN.
- If the FortiClient dialup clients will be configured to obtain VIP addresses through FortiGate DHCP relay, a DHCP server must be available on the network behind the FortiGate unit and the DHCP server must have a direct route to the FortiGate unit.
- If the FortiGate interface to the private network is not the default gateway, the private network behind the FortiGate unit must be configured to route IP traffic destined for dialup clients back (through an appropriate gateway) to the FortiGate interface to the private network. As an alternative, you can configure the IPsec security policy on the FortiGate unit to perform inbound NAT on IP packets. Inbound NAT translates the source addresses of inbound decrypted packets into the IP address of the FortiGate interface to the local private network.

Configuring the FortiGate unit

Configuring the FortiGate unit to establish VPN connections with FortiClient Endpoint Security users involves the following steps:

- Configure the VPN settings
- If the dialup clients use automatic configuration, configure the FortiGate unit as a VPN policy server
- If the dialup clients obtain VIP addresses by DHCP over IPsec, configure an IPsec DHCP server or relay

The procedures in this section cover basic setup of policy-based and route-based VPNs compatible with FortiClient Endpoint Security. A route-based VPN is simpler to configure.

The IPsec VPN Wizard greatly simplifies IPsec VPN tunnel creation for route-based tunnels.

To configure FortiGate unit VPN settings to support FortiClient users, you need to:

- Configure the FortiGate Phase 1 VPN settings
- Configure the FortiGate Phase 2 VPN settings
- Add the security policy

On the local FortiGate unit, define the Phase 1 configuration needed to establish a secure connection with the FortiClient peer. See [Phase 1 parameters on page 1655](#).

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit **Network** (full configuration options are only available once you click the **Convert To Custom Tunnel** button).
3. Enter these settings in particular:

Remote Gateway	Select Dialup User .
IP Address	Enter the IP address of the remote peer.
Interface	Select the interface through which clients connect to the FortiGate unit.
Mode Config	When enabled, further options become available: <ul style="list-style-type: none"> • Client Address Range • Subnet Mask • Use System DNS • DNS Server • Enable IPv4 Split Tunnel
Authentication Method	Select Pre-shared Key .
Pre-shared Key	Enter the pre-shared key. This must be the same preshared key provided to the FortiClient users.
Peer option	Select Any peer ID .

4. Edit **Authentication** and enter the following information:

Method	Select Pre-shared Key .
Pre-shared Key	Enter the pre-shared key. This must be the same preshared key provided to the FortiClient users.
Peer Options	Set Accept Types to Any peer ID .

5. Define the Phase 2 parameters needed to create a VPN tunnel with the FortiClient peer. See [Phase 2 parameters on page 1675](#). Enter these settings in particular:

Name	Enter a name to identify this Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined.
Advanced	Select to configure the following optional setting.
DHCP-IPsec	Select if you provide virtual IP addresses to clients using DHCP.

6. Define names for the addresses or address ranges of the private networks that the VPN links. These addresses are used in the security policies that permit communication between the networks. For more information, see [Defining policy addresses on page 1](#).

Enter these settings in particular:

- Define an address name for the individual address or the subnet address that the dialup users access through the VPN.
 - If FortiClient users are assigned VIP addresses, define an address name for the subnet to which these VIPs belong.
4. Define security policies to permit communication between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see [Defining VPN security policies on page 1](#).

If the security policy, which grants the VPN Connection is limited to certain services, DHCP must be included, otherwise the client won't be able to retrieve a lease from the FortiGate's (IPsec) DHCP server, because the DHCP Request (coming out of the tunnel) will be blocked.

Route-based VPN security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Name	Enter an appropriate name for the policy.
Incoming Interface	Select the VPN Tunnel (IPsec Interface) you configured in Step "Configuration overview" on page 1736 .
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.

Source	Select all .
Destination Address	Select all .
Action	Select ACCEPT .
NAT	Disable NAT .

If you want to allow hosts on the private network to initiate communications with the FortiClient users after the tunnel is established, you need to define a security policy for communication in that direction.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source	Select all .
Destination Address	Select all .
Action	Select ACCEPT .
NAT	Disable NAT .

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the FortiGate unit's public interface.
Source	Select the address name that you defined in Step "Configuration overview" on page 1736 for the private network behind this FortiGate unit.
Destination Address	If FortiClient users are assigned VIPs, select the address name that you defined for the VIP subnet. Otherwise, select all .
Action	Select IPsec . Under VPN Tunnel , select the name of the Phase 1 configuration that you created in Step "Configuration overview" on page 1736 from the drop-down list. Select Allow traffic to be initiated from the remote site .

Place VPN policies in the policy list above any other policies having similar source and destination addresses.

Configuring the FortiGate unit as a VPN policy server

When a FortiClient application set to automatic configuration connects to the FortiGate unit, the FortiGate unit requests a user name and password. If the user supplies valid credentials, the FortiGate unit downloads the VPN settings to the FortiClient application.

You must do the following to configure the FortiGate unit to work as a VPN policy server for FortiClient automatic configuration:

1. Create user accounts for FortiClient users.
2. Create a user group for FortiClient users and the user accounts that you created in step 1.
3. Connect to the FortiGate unit CLI and configure VPN policy distribution as follows:

```
config vpn ipsec forticlient
  edit <policy_name>
    set phase2name <tunnel_name>
    set usergroupname <group_name>
    set status enable
  end
```

<tunnel_name> must be the Name you specified in the step 2 of [Configuration overview on page 1736](#).

<group_name> must be the name of the user group your created for FortiClient users.

Configuring DHCP services on a FortiGate interface

If the FortiClient dialup clients are configured to obtain a VIP address using DHCP, configure the FortiGate dialup server to either:

- Relay DHCP requests to a DHCP server behind the FortiGate unit (see [Configuring DHCP relay on a FortiGate interface on page 1743](#) below).
- Act as a DHCP server (see [Configuring a DHCP server on a FortiGate interface on page 1743](#)).

Note that DHCP services are typically configured during the interface creation stage, but you can return to an interface to modify DHCP settings if need be.

Configuring DHCP relay on a FortiGate interface

1. Go to **Network > Interfaces** and select the interface that you want to relay DHCP.
2. Enable **DHCP Server**, and create a new DHCP **Address Range** and **Netmask**.
3. Open the **Advanced...** menu and set **Mode** to **Relay**.
4. Enter the **DHCP Server IP**.
5. Select **OK**.

Configuring a DHCP server on a FortiGate interface

1. Go to **Network > Interfaces** and select the interface that you want to act as a DHCP server.
2. Enable **DHCP Server**, and create a new DHCP **Address Range** and **Netmask**.
3. Set **Default Gateway** to **Specify**, and enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
4. Set **DNS Server** to **Same as System DNS**. If you want to use a different DNS server for VPN clients, select **Specify** and enter an IP address in the available field.

5. Open the **Advanced...** menu and set **Mode** to **Server**.
6. Select **OK**.

Configure the FortiClient Endpoint Security application

The following procedure explains how to configure the FortiClient Endpoint Security application to communicate with a remote FortiGate dialup server using the VIP address that you specify manually. These procedures are based on FortiClient 5.4.1.

Configuring FortiClient

This procedure explains how to configure the FortiClient application manually using the default IKE and IPsec settings. For more information, refer to the FortiClient Administration Guide.

1. Go to **Remote Access** and select the **Settings** icon.
2. Select **Add a new connection**, set the new VPN connection to **IPsec VPN**, and complete following information:

Connection Name	Enter a descriptive name for the connection.
Remote Gateway	Enter the IP address or the fully qualified domain name (FQDN) of the remote gateway.
Authentication Method	Select Pre-shared Key and enter the pre-shared key in the field provided.
Authentication (XAuth)	<p>Extended Authentication (XAuth) increases security by requiring additional user authentication in a separate exchange at the end of the VPN Phase 1 negotiation. The FortiGate unit challenges the user for a user name and password. It then forwards the user's credentials to an external RADIUS or LDAP server for verification.</p> <p>Implementation of XAuth requires configuration at both the FortiGate unit and the FortiClient application.</p>

3. Select **OK**.

Adding XAuth authentication

For information about configuring a FortiGate unit as an XAuth server, see [Phase 1 parameters on page 1655](#). The following procedure explains how to configure the FortiClient application.

Note that XAuth is not compatible with IKE version 2.

For more information on configuring XAuth authentication, see the [FortiClient Administration Guide](#).

FortiGate dialup-client configurations

This section explains how to set up a FortiGate dialup-client IPsec VPN. In a FortiGate dialup-client configuration, a FortiGate unit with a static IP address acts as a dialup server and a FortiGate unit having a dynamic IP address initiates a VPN tunnel with the FortiGate dialup server.

The following topics are included in this section:

Configuration overview

A dialup client can be a FortiGate unit. The FortiGate dialup client typically obtains a dynamic IP address from an ISP through the Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol over Ethernet (PPPoE) before initiating a connection to a FortiGate dialup server.

Example FortiGate dialup-client configuration

In a dialup-client configuration, the FortiGate dialup server does not rely on a Phase 1 remote gateway address to establish an IPsec VPN connection with dialup clients. As long as authentication is successful and the IPsec security policy associated with the tunnel permits access, the tunnel is established.

Several different ways to authenticate dialup clients and restrict access to private networks based on client credentials are available. To authenticate FortiGate dialup clients and help to distinguish them from FortiClient dialup clients when multiple clients will be connecting to the VPN through the same tunnel, best practices dictate that you assign a unique identifier (local ID or peer ID) to each FortiGate dialup client. For more information, see [Phase 1 parameters on page 1655](#).

Whenever you add a unique identifier (local ID) to a FortiGate dialup client for identification purposes, you must select Aggressive mode on the FortiGate dialup server and also specify the identifier as a peer ID on the FortiGate dialup server. For more information, see [Phase 1 parameters on page 1655](#).

Users behind the FortiGate dialup server cannot initiate the tunnel because the FortiGate dialup client does not have a static IP address. After the tunnel is initiated by users behind the FortiGate dialup client, traffic from the private network behind the FortiGate dialup server can be sent to the private network behind the FortiGate dialup client.

Encrypted packets from the FortiGate dialup client are addressed to the public interface of the dialup server. Encrypted packets from the dialup server are addressed either to the public IP address of the FortiGate dialup client (if the dialup client connects to the Internet directly), or if the FortiGate dialup client is behind a NAT device, encrypted packets from the dialup server are addressed to the public IP address of the NAT device.

If a router with NAT capabilities is in front of the FortiGate dialup client, the router must be NAT-T compatible for encrypted traffic to pass through the NAT device. For more information, see [Phase 1 parameters on page 1655](#).

When the FortiGate dialup server decrypts a packet from the FortiGate dialup client, the source address in the IP header may be one of the following values, depending on the configuration of the network at the far end of the tunnel:

- If the FortiGate dialup client connects to the Internet directly, the source address will be the private IP address of a host or server on the network behind the FortiGate dialup client.
- If the FortiGate dialup client is behind a NAT device, the source address will be the public IP address of the NAT device.

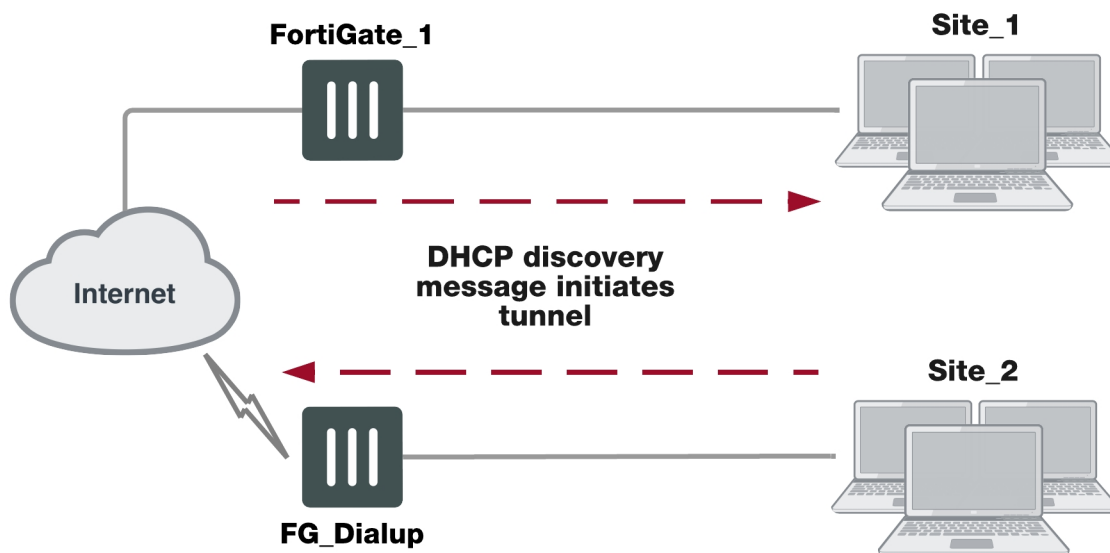

In some cases, computers on the private network behind the FortiGate dialup client may (by co-incidence) have IP addresses that are already used by computers on the network behind the FortiGate dialup server. In this type of situation (ambiguous routing), conflicts may occur in one or both of the FortiGate routing tables and traffic destined for the remote network through the tunnel may not be sent.

In many cases, computers on the private network behind the FortiGate dialup client will most likely obtain IP addresses from a local DHCP server behind the FortiGate dialup client. However, unless the local and remote networks use different private network address spaces, unintended ambiguous routing and IP-address overlap issues may arise.

To avoid these issues, you can configure FortiGate DHCP relay on the dialup client instead of using a DHCP server on the network behind the dialup client. The FortiGate dialup client can be configured to relay DHCP requests from the local private network to a DHCP server that resides on the network behind the FortiGate dialup server. You configure the FortiGate dialup client to pass traffic from the local private network to the remote network by enabling FortiGate DHCP relay on the FortiGate dialup client interface that is connected to the local private network.

Afterward, when a computer on the network behind the dialup client broadcasts a DHCP request, the dialup client relays the message through the tunnel to the remote DHCP server. The remote DHCP server responds with a private IP address for the computer. To avoid ambiguous routing and network overlap issues, the IP addresses assigned to computers behind the dialup client cannot match the network address space used by the private network behind the FortiGate dialup server.

Preventing network overlap in a FortiGate dialup-client configuration

When the DHCP server resides on the private network behind the FortiGate dialup server, the IP destination address specified in the IPsec security policy on the FortiGate dialup client must refer to that network.

You must add a static route to the DHCP server FortiGate unit if it is not directly connected to the private network behind the FortiGate dialup server; its IP address does not match the IP address of the private network. Also, the destination address in the IPsec security policy on the FortiGate dialup client must refer to the DHCP server address. The DHCP server must be configured to assign a range of IP addresses different from the DHCP server's local network, and also different from the private network addresses behind the FortiGate dialup server. See [Routing on page 1](#).

FortiGate dialup-client infrastructure requirements

The requirements are:

- The FortiGate dialup server must have a static public IP address.
- NAT mode is required if you want to create a route-based VPN.
- The FortiGate dialup server may operate in either NAT mode or transparent mode to support a policy-based VPN.
- Computers on the private network behind the FortiGate dialup client can obtain IP addresses either from a DHCP server behind the FortiGate dialup client, or a DHCP server behind the FortiGate dialup server.
 - If the DHCP server resides on the network behind the dialup client, the DHCP server must be configured to assign IP addresses that do not match the private network behind the FortiGate dialup server.
 - If the DHCP server resides on the network behind the FortiGate dialup server, the DHCP server must be configured to assign IP addresses that do not match the private network behind the FortiGate dialup client.

Configuring the server to accept FortiGate dialup-client connections

The procedures in this section assume that computers on the private network behind the FortiGate dialup client obtain IP addresses from a local DHCP server. The assigned IP addresses do not match the private network

behind the FortiGate dialup server.

In situations where IP-address overlap between the local and remote private networks is likely to occur, FortiGate DHCP relay can be configured on the FortiGate dialup client to relay DHCP requests to a DHCP server behind the FortiGate dialup server. For more information, see [To configure DHCP relay on a FortiGate interface on page 1](#).

Configuring dialup client capability for FortiGate dialup clients involves the following general configuration steps:

- Determine which IP addresses to assign to the private network behind the FortiGate dialup client, and add the IP addresses to the DHCP server behind the FortiGate dialup client. Refer to the software supplier's documentation to configure the DHCP server.
- Configure the FortiGate dialup server. See [Configuration overview on page 1745](#).
- Configure the FortiGate dialup client. See [Configuration overview on page 1745](#).

Before you begin, optionally reserve a unique identifier (peer ID) for the FortiGate dialup client. The dialup client will supply this value to the FortiGate dialup server for authentication purposes during the IPsec Phase 1 exchange. In addition, the value will enable you to distinguish FortiGate dialup-client connections from FortiClient dialup-client connections. The same value must be specified on the dialup server and on the dialup client.

In circumstances where multiple remote dialup VPN tunnels exist, each tunnel must have a peer ID set.

At the FortiGate dialup server, define the Phase 1 parameters needed to authenticate the FortiGate dialup client and establish a secure connection. See [Phase 1 parameters on page 1655](#).

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit **Network** (full configuration options are only available once you click the **Convert To Custom Tunnel** button).
3. Enter these settings in particular:

Remote Gateway	Select Dialup User .
Interface	Select the interface through which clients connect to the FortiGate unit.

4. Edit **Authentication** and enter the following information:

Mode	If you will be assigning an ID to the FortiGate dialup client, select Aggressive .
Peer Options	If you will be assigning an ID to the FortiGate dialup client, set Accept Types to This peer ID and type the identifier that you reserved for the FortiGate dialup client into the adjacent field.

5. Define the Phase 2 parameters needed to create a VPN tunnel with the FortiGate dialup client. See [Phase 2 parameters on page 1675](#). Enter these settings in particular:

Name	Enter a name to identify this Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined.

- Define names for the addresses or address ranges of the private networks that the VPN links. See [Defining policy addresses on page 1](#). Enter these settings in particular:
 - Define an address name for the server, host, or network behind the FortiGate dialup server.
 - Define an address name for the private network behind the FortiGate dialup client.
- Define the security policies to permit communications between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see [Defining VPN security policies on page 1](#).

Route-based VPN security policy

Define an ACCEPT security policy to permit communications between hosts on the private network behind the FortiGate dialup client and the private network behind this FortiGate dialup server. Because communication cannot be initiated in the opposite direction, there is only one policy.

- Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
- Enter these settings in particular:

Name	Enter an appropriate name for the policy.
Incoming Interface	Select the VPN tunnel (IPsec interface) created in Step 1.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source	Select all .
Destination Address	Select all .
Action	Select ACCEPT .
NAT	Disable NAT .

Policy-based VPN security policy

- Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
- Enter these settings in particular:

Name	Enter an appropriate name for the policy.
Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the FortiGate unit's public interface.
Source	Select the address name that you defined for the private network behind this FortiGate unit.

Destination Address	Select the address name that you defined.
Action	Select IPsec . Under VPN Tunnel , select the name of the Phase 1 configuration that you created in Step " Configuration overview " on page 1745 from the drop-down list. Select Allow traffic to be initiated from the remote site .

- To prevent traffic from the local network from initiating the tunnel after the tunnel has been established, you need to disable the outbound VPN traffic in the CLI

```
config firewall policy
  edit <policy_number>
    set outbound disable
end
```

Place the policy in the policy list above any other policies having similar source and destination addresses.

If configuring a route-based policy, configure a default route for VPN traffic on this interface.

Configuring the FortiGate dialup client

At the FortiGate dialup client, define the Phase 1 parameters needed to authenticate the dialup server and establish a secure connection. See [Phase 1 parameters on page 1655](#).

- Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
- Edit **Network** (full configuration options are only available once you click the **Convert To Custom Tunnel** button).
- Enter these settings in particular:

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the dialup server's public interface.
Interface	Select the interface that connects to the public network.
Mode	The FortiGate dialup client has a dynamic IP address, select Aggressive .
Advanced	Select to view the following options.
Local ID	If you defined a peer ID for the dialup client in the FortiGate dialup server configuration, enter the identifier of the dialup client. The value must be identical to the peer ID that you specified previously in the FortiGate dialup server configuration.

- Edit **Authentication** and enter the following information:

Mode	The FortiGate dialup client has a dynamic IP address, select Aggressive .
-------------	--

- Edit **Phase 1 Proposal** and enter the following information:

Local ID	If you defined a peer ID for the dialup client in the FortiGate dialup server configuration, enter the identifier of the dialup client. The value must be identical to the peer ID that you specified previously in the FortiGate dialup server configuration.
-----------------	--

- Define the Phase 2 parameters needed to create a VPN tunnel with the dialup server. See [Phase 2 parameters on page 1675](#). Enter these settings in particular:

Name	Enter a name to identify this Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined.

- Define names for the addresses or address ranges of the private networks that the VPN links. See [Defining policy addresses on page 1](#). Enter these settings in particular:
 - Define an address name for the server, host, or network behind the FortiGate dialup server.
 - Define an address name for the private network behind the FortiGate dialup client.
- Define security policies to permit communication between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see [Defining VPN security policies on page 1](#).

Route-based VPN security policy

Define an ACCEPT security policy to permit communications between hosts on the private network behind this FortiGate dialup client and the private network behind the FortiGate dialup server. Because communication cannot be initiated in the opposite direction, there is only one policy.

- Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
- Enter these settings in particular:

Name	Enter an appropriate name for the policy.
Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the VPN tunnel (IPsec interface) created in Step 1.
Source	Select all .
Destination Address	Select all .
Action	Select ACCEPT .
NAT	Disable NAT .

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

- Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
- Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the FortiGate unit's public interface.
Source	Select the address name that you defined for the private network behind this FortiGate unit.
Destination Address	Select the address name that you defined for the private network behind the dialup server.
Action	<p>Select IPsec. Under VPN Tunnel, select the name of the Phase 1 configuration that you created in Step "Configuration overview " on page 1745 from the drop-down list.</p> <p>Clear Allow traffic to be initiated from the remote site to prevent traffic from the remote network from initiating the tunnel after the tunnel has been established.</p>

Place the policy in the policy list above any other policies having similar source and destination addresses.

IPsec dial-up interface sharing

It is possible to use a single interface for all instances that spawn via a given phase1. In this case, instead of creating an interface per instance, all traffic will run over the single interface and any routes that need creating will be created on that single interface.

The CLI option `"net-device [enable|disable]"` is available in the phase1-interface command sets. Under the new single-interface scheme, instead of relying on routing to guide traffic to the specific instance, all traffic will flow to the specific device and IPsec will need to take care of locating the correct instance for outbound traffic. For this purpose, the CLI option `"tunnel-search"` is provided. The option is only available when the above `"net-device"` option is `"disable"`.

There are two options for `"tunnel-search"`, corresponding to the two ways to select the tunnel for outbound traffic. One is `"selectors"`, meaning selecting a peer using the IPsec selectors (proxy-ids). The other is `"nexthop"` where all the peers use the same default selectors (0/0) while using some routing protocols such as BGP, OSPF, RIPng, etc to resolve the routing. The default for `"tunnel-search"` is `"selectors"`.

Syntax

```

config vpn ipsec phase1-interface
    edit xxx
        set net-device [enable|disable] Enable to create a kernel device for every dialup instance
    next
end
config vpn ipsec phase1-interface
    edit xxx
        set net-device disable
        set tunnel-search [selectors|nexthop] Search for tunnel in selectors or using nexthops
    next
end

```

Supporting IKE Mode Config clients

IKE Mode Config is an alternative to DHCP over IPsec. A FortiGate unit can be configured as either an IKE Mode Config server or client. This chapter contains the following sections:

IKE Mode Config overview

Dialup VPN clients connect to a FortiGate unit that acts as a VPN server, providing the client the necessary configuration information to establish a VPN tunnel. The configuration information typically includes a virtual IP address, netmask, and DNS server address.

IKE Mode Config is available only for VPNs that are route-based, also known as interface-based. A FortiGate unit can function as either an IKE Configuration Method server or client. IKE Mode Config is configurable only in the CLI.

Automatic configuration overview

VPN configuration for remote clients is simpler if it is automated. Several protocols support automatic configuration:

- The Fortinet FortiClient Endpoint Security application can completely configure a VPN connection with a suitably configured FortiGate unit given only the FortiGate unit's address. This protocol is exclusive to Fortinet. For more information, see [FortiClient dialup-client configurations on page 1](#).
- DHCP over IPsec can assign an IP address, Domain, DNS and WINS addresses. The user must first configure IPsec parameters such as gateway address, encryption and authentication algorithms.
- IKE Mode Config can configure host IP address, Domain, DNS and WINS addresses. The user must first configure IPsec parameters such as gateway address, encryption and authentication algorithms. Several network equipment vendors support IKE Mode Config, which is described in the ISAKMP Configuration Method document [draft-dukes-ike-mode-cfg-02.txt](#).

This chapter describes how to configure a FortiGate unit as either an IKE Mode Config server or client.

IKE Mode Config method

IKE Mode Config is configured with the CLI command `config vpn ipsec phase1-interface`. The `mode-cfg` variable enables IKE Mode Config. The `type` field determines whether you are creating an IKE Mode Config server or a client. Setting `type` to `dynamic` creates a server configuration, otherwise the configuration is a client.

Creating an IKE Mode Config client

If the FortiGate unit will connect as a dialup client to a remote gateway that supports IKE Mode Config, the relevant `vpn ipsec phase1-interface` variables are as follows:

Variable	Description
<code>ike-version 1</code>	IKE v1 is the default for FortiGate IPsec VPNs. IKE Mode Config is also compatible with IKE v2 (RFC 4306). Use syntax <code>ike-version 2</code> .
<code>mode-cfg enable</code>	Enable IKE Mode Config.
<code>type {ddns static}</code>	If you set <code>type</code> to <code>dynamic</code> , an IKE Mode Config server is created.
<code>assign-ip {enable disable}</code>	Enable to request an IP address from the server.
<code>interface <interface_name></code>	This is a regular IPsec VPN field. Specify the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound.
<code>proposal <encryption_combination></code>	This is a regular IPsec VPN field that determines the encryption and authentication settings that the client will accept. For more information, see Phase 1 parameters on page 1655 .
<code>ip-version <4 6></code>	This is a regular IPsec VPN field. By default, IPsec VPNs use IPv4 addressing. You can set <code>ip-version</code> to <code>6</code> to create a VPN with IPv6 addressing.
<code>ipv4-split-exclude</code> <code>ipv6-split-exclude</code>	This command allows the administrator to specify that default traffic flows over the IPsec tunnel except for specified subnets. This is the opposite of the supported <code>split-include</code> feature which allows the administrator to specify that default traffic should not flow over the IPsec tunnel except for specified subnets.

For a complete list of available variables, see the [CLI Reference](#).

IKE Mode Config client example - CLI

In this example, the FortiGate unit connects to a VPN gateway with a static IP address that can be reached through Port 1. Only the port, gateway and proposal information needs to be configured. All other configuration information will come from the IKE Mode Config server.

```
config vpn ipsec phase1-interface
  edit vpn1
    set ip-version 4
    set type static
    set remote-gw <gw_address>
    set interface port 1
    set proposal 3des-sha1 aes128-sha1
    set mode-cfg enable
    set assign-ip enable
  end
```

Creating an IKE Mode Config server

If the FortiGate unit will accept connection requests from dialup clients that support IKE Mode Config, the following `vpn ipsec phase1-interface` settings are required before any other configuration is attempted:

Variable	Description
<code>ike-version 1</code>	IKE v1 is the default for FortiGate IPsec VPNs. IKE Mode Config is also compatible with IKE v2 (RFC 4306). Use syntax <code>ike-version 2</code> .
<code>mode-cfg enable</code>	Enable IKE Mode Config.
<code>type dynamic</code>	Any other setting creates an IKE Mode Config client.
<code>interface <interface_name></code>	This is a regular IPsec VPN field. Specify the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound.
<code>proposal <encryption_combination></code>	This is a regular IPsec VPN field that determines the encryption and authentication settings that the server will accept. For more information, see Phase 1 parameters on page 1655 .
<code>ip-version <4 6></code>	This is a regular IPsec VPN field. By default, IPsec VPNs use IPv4 addressing. You can set <code>ip-version</code> to <code>6</code> to create a VPN with IPv6 addressing.

IKE Mode Config server example - CLI

In this example, the FortiGate unit assigns IKE Mode Config clients addresses in the range of 10.11.101.160 through 10.11.101.180. DNS and WINS server addresses are also provided. The public interface of the FortiGate unit is Port 1.

When IKE Mode-Configuration is enabled, multiple server IPs can be defined in IPsec Phase 1.

The `ipv4-split-include` variable specifies a firewall address that represents the networks to which the clients will have access. This destination IP address information is sent to the clients.

Only the CLI fields required for IKE Mode Config are shown here. For detailed information about these variables, see the FortiGate CLI Reference.

```
config vpn ipsec phase1-interface
edit "vpn-p1"
    set type dynamic
    set interface "wan1"
    set xauthtype auto
    set mode aggressive
    set mode-cfg enable
    set proposal 3des-sha1 aes128-sha1
    set dpd disable
    set dhgrp 2
    set xauthexpire on-rekey
    set authusrgrp "FG-Group1"
```

```
set ipv4-start-ip 10.10.10.10
set ipv4-end-ip 10.10.10.20
set ipv4-dns-server1 1.1.1.1
set ipv4-dns-server2 2.2.2.2
set ipv4-dns-server3 3.3.3.3
set ipv4-wins-server1 4.4.4.4
set ipv4-wins-server2 5.5.5.5
set domain "fgt1c-domain"
set banner "fgt111C-banner"
set backup-gateway "100.100.100.1" "host1.com" "host2"
set ipv4-split-include OfficeLAN
end
```

IP address assignment

After you have enabled the basic configuration, you can configure IP address assignment for clients, as well as DNS and WINS server assignment. Usually you will want to assign IP addresses to clients.

The simplest method to assign IP addresses to clients is to assign addresses from a specific range, similar to a DHCP server.

If your clients are authenticated by a RADIUS server, you can obtain the user's IP address assignment from the Framed-IP-Address attribute. The user must be authenticated using XAuth.

IKE Mode Config can also use a remote DHCP server to assign the client IP addresses. Up to eight addresses can be selected for either IPv4 or IPv6. After the DHCP proxy has been configured, the `assign-ip-from` command is used to assign IP addresses via DHCP.

Assigning IP addresses from an address range - CLI

If your VPN uses IPv4 addresses,

```
config vpn ipsec phase1-interface
edit vpn1
set mode-cfg-ipversion 4
set assign-ip enable
set assign-ip-type ip
set assign-ip-from range
set ipv4-start-ip <range_start>
set ipv4-end-ip <range_end>
set ipv4-netmask <netmask>
end
```

If your VPN uses IPv6 addresses,

```
config vpn ipsec phase1-interface
edit vpn1
set mode-cfg-ipversion 6
set assign-ip enable
set assign-ip-type ip
set assign-ip-from range
set ipv6-start-ip <range_start>
set ipv6-end-ip <range_end>
end
```

Assigning IP addresses from a RADIUS server - CLI

The users must be authenticated by a RADIUS server and assigned to the FortiGate user group <grpname>. Since the IP address will not be static, `type` is set to `dynamic`, and `mode-cfg` is enabled. This is IKE Configuration Method so that compatible clients can configure themselves with settings that the FortiGate unit provides.

```
config vpn ipsec phase1-interface
  edit vpn1
    set type dynamic
    set mode-cfg enable
    set assign-ip enable
    set assign-ip-from usrgrp
    set xauthtype auto
    set authusrgrp <grpname>
  end
```

Assigning IP address from DHCP - CLI

The DHCP proxy must first be enabled for IKE Mode Config to use DHCP to assign the VPN client IP address(es).

```
config system settings
  set dhcp-proxy enable
  set dhcp-server-ip [ipv4 address]
  set dhcp6-server-ip [ipv6-address]
```

(Up to eight server addresses can be configured)

```
end

config vpn ipsec phase1-interface
  edit vpn1
    set mode-cfg enable
    set assign-ip-from dhcp
  next
end
```

Assigning IP address from a named firewall address/group - CLI

```
config vpn ipsec phase1-interface
  edit <name>vpn1
    set type dynamic
    set assign-ip-from name
    set ipv4-name <name>
    set ipv6-name <name>
  next
end
```

Certificate groups

IKE certificate groups consisting of up to four RSA certificates can be used in IKE Phase 1. Since CA and local certificates are global, the IKE daemon loads them once for all VDOMs and indexes them into trees based on subject and public key hash (for CA certificates), or certificate name (for local certificates). Certificates are linked together based on the issuer, and certificate chains are built by traversing these links. This reduces the need to keep multiple copies of certificates that could exist in multiple chains.

IKE certificate groups can be configured through the CLI.

Configuring the IKE local ID - CLI

```
config vpn certificate local
edit <name>
    set ike-localid <string>
    set ike-localid-type {asn1dn | fqdn}
end
```

Split-exclude in IKEv1 mode-cfg

This feature allows the administrator to specify when using IKEv1 Configuration Method that default traffic flows over the IPsec tunnel except for specified subnets. This is the opposite of the supported `split-include` feature which allows the administrator to specify that default traffic should not flow over the IPsec tunnel except for specified subnets.

The `split-include` and `split-exclude` options can both be specified at the same time. Whether a client does the right thing when both are specified depends on the client.

Syntax

```
config vpn ipsec {phase1 | phase1-interface}
edit <name>
    set ike-version 1
    set type dynamic
    set mode-cfg enable
    set ipv4-split-exclude {all | none | address}
    set ipv6-split-exclude {all | none | address}
next
end
```

Internet-browsing configuration

This section explains how to support secure web browsing performed by dialup VPN clients, and/or hosts behind a remote VPN peer. Remote users can access the private network behind the local FortiGate unit and browse the Internet securely. All traffic generated remotely is subject to the security policy that controls traffic on the private network behind the local FortiGate unit.

The following topics are included in this section:

Configuration overview

A VPN provides secure access to a private network behind the FortiGate unit. You can also enable VPN clients to access the Internet securely. The FortiGate unit inspects and processes all traffic between the VPN clients and hosts on the Internet according to the Internet browsing policy. This is accomplished even though the same FortiGate interface is used for both encrypted VPN client traffic and unencrypted Internet traffic.

In the figure below, FortiGate_1 enables secure Internet browsing for FortiClient Endpoint Security users such as Dialup_1 and users on the Site_2 network behind FortiGate_2, which could be a VPN peer or a dialup client.

Example Internet-browsing configuration

You can adapt any of the following configurations to provide secure Internet browsing:

- A gateway-to-gateway configuration (see [Gateway-to-gateway configurations on page 1](#))
- A FortiClient dialup-client configuration (see [FortiClient dialup-client configurations on page 1](#))
- A FortiGate dialup-client configuration (see [FortiGate dialup-client configurations on page 1](#))

The procedures in this section assume that one of these configurations is in place, and that it is operating properly.

To create an internet-browsing configuration based on an existing gateway-to-gateway configuration, you must edit the gateway-to-gateway configuration as follows:

- On the FortiGate unit that will provide Internet access, create an Internet browsing security policy. See [Configuration overview on page 1759](#), below.
- Configure the remote peer or client to route all traffic through the VPN tunnel. You can do this on a FortiGate unit or on a FortiClient Endpoint Security application. See [Configuration overview on page 1759](#).

Creating an Internet browsing security policy

On the FortiGate unit that acts as a VPN server and will provide secure access to the Internet, you must create an Internet browsing security policy. This policy differs depending on whether your gateway-to-gateway configuration is policy-based or route-based.

Creating an Internet browsing policy - policy-based VPN

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	Enter an appropriate name for the policy.
Incoming Interface	The interface to which the VPN tunnel is bound.
Outgoing Interface	The interface to which the VPN tunnel is bound.
Source	The internal range address of the remote spoke site.
Destination Address	all
Action	Select IPsec . Under VPN Tunnel , select the tunnel that provides access to the private network behind the FortiGate unit. Select Allow traffic to be initiated from the remote site .
NAT	Enable NAT .

Creating an Internet browsing policy - route-based VPN

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	Enter an appropriate name for the policy.
Incoming Interface	The IPsec VPN interface.

Outgoing Interface	The interface that connects to the Internet. The virtual IPsec interface is configured on this physical interface.
Source	The internal range address of the remote spoke site.
Destination Address	all
Action	ACCEPT
NAT	Enable NAT .

The VPN clients must be configured to route all Internet traffic through the VPN tunnel.

Routing all remote traffic through the VPN tunnel

To make use of the Internet browsing configuration on the VPN server, the VPN peer or client must route all traffic through the VPN tunnel. Usually, only the traffic destined for the private network behind the FortiGate VPN server is sent through the tunnel.

The remote end of the VPN can be a FortiGate unit that acts as a peer in a gateway-to-gateway configuration, or a FortiClient application that protects an individual client PC.

- To configure a remote peer FortiGate unit for Internet browsing via VPN, see [Configuring a FortiGate remote peer to support Internet browsing on page 1761](#).
- To configure a FortiClient Endpoint Security application for Internet browsing via VPN, see [Configuring a FortiClient application to support Internet browsing on page 1762](#).

These procedures assume that your VPN connection to the protected private network is working and that you have configured the FortiGate VPN server for Internet browsing as described in [Configuration overview on page 1759](#).

Configuring a FortiGate remote peer to support Internet browsing

The configuration changes to send all traffic through the VPN differ for policy-based and route-based VPNs.

Routing all traffic through a policy-based VPN

1. At the FortiGate dialup client, go to **Policy & Objects > IPv4 Policy**.
2. Select the IPsec security policy and then select **Edit**.
3. From the **Destination Address** list, select **all**.
4. Select **OK**.

Packets are routed through the VPN tunnel, not just those destined for the protected private network.

Routing all traffic through a route-based VPN

1. At the FortiGate dialup client, go to **Network > Static Routes**.
2. Select the default route (destination IP 0.0.0.0) and then select **Edit**. If there is no default route, select **Create New**. Enter the following information and select **OK**:

Destination IP/Mask	Set to Subnet and enter 0.0.0.0/0.0.0.0 in the field provided.
----------------------------	--

Device	Select the IPsec virtual interface.
Administrative Distance	Leave at default.

All packets are routed through the VPN tunnel, not just packets destined for the protected private network.

Configuring a FortiClient application to support Internet browsing

By default, the FortiClient application configures the PC so that traffic destined for the remote protected network passes through the VPN tunnel but all other traffic is sent to the default gateway. You need to modify the FortiClient settings so that it configures the PC to route all outbound traffic through the VPN.

Routing all traffic through VPN - FortiClient application

1. At the remote host, start FortiClient.
2. Go to **Remote Access**.
3. Select the definition that connects FortiClient to the FortiGate dialup server, select the **Settings** icon, and select **Edit the selected connection**.
4. In the **Edit VPN Connection** dialog box, select **Advanced Settings**.
5. In the **Remote Network** group, select **Add**.
6. In the **IP** and **Subnet Mask** fields, type `0.0.0.0/0.0.0.0` and select **OK**.

The address is added to the **Remote Network** list. The first destination IP address in the list establishes a VPN tunnel. The second destination address (`0.0.0.0/0.0.0.0` in this case) forces all other traffic through the VPN tunnel.

7. Select **OK**.

Redundant VPN configurations

This section discusses the options for supporting redundant and partially redundant IPsec VPNs, using route-based approaches.

The following topics are included in this section:

Configuration overview

A FortiGate unit with two interfaces connected to the Internet can be configured to support redundant VPNs to the same remote peer. If the primary connection fails, the FortiGate unit can establish a VPN using the other connection.

Redundant tunnels do not support Tunnel Mode or manual keys. You must use Interface Mode.

A fully-redundant configuration requires redundant connections to the Internet on both peers. The figure below shows an example of this. This is useful to create a reliable connection between two FortiGate units with static IP addresses.

When only one peer has redundant connections, the configuration is partially-redundant. For an example of this, see [Configuration overview on page 1763](#). This is useful to provide reliable service from a FortiGate unit with static IP addresses that accepts connections from dialup IPsec VPN clients.

In a fully-redundant VPN configuration with two interfaces on each peer, four distinct paths are possible for VPN traffic from end to end. Each interface on a peer can communicate with both interfaces on the other peer. This ensures that a VPN will be available as long as each peer has one working connection to the Internet.

You configure a VPN and an entry in the routing table for each of the four paths. All of these VPNs are ready to carry data. You set different routing distances for each route and only the shortest distance route is used. If this route fails, the route with the next shortest distance is used.

The redundant configurations described in this chapter use route-based VPNs, otherwise known as virtual IPsec interfaces. This means that the FortiGate unit must operate in NAT mode. You must use auto-keying. A VPN that is created using manual keys cannot be included in a redundant-tunnel configuration.

The configuration described here assumes that your redundant VPNs are essentially equal in cost and capability. When the original VPN returns to service, traffic continues to use the replacement VPN until the replacement VPN fails. If your redundant VPN uses more expensive facilities, you want to use it only as a backup while the main VPN is down. For information on how to do this, see [Configuration overview on page 1763](#).

Example redundant-tunnel configuration

A VPN that is created using manual keys cannot be included in a redundant-tunnel configuration.

General configuration steps

A redundant configuration at each VPN peer includes:

- One Phase 1 configuration (virtual IPsec interface) for each path between the two peers. In a fully-meshed redundant configuration, each network interface on one peer can communicate with each network interface on the remote peer. If both peers have two public interfaces, this means that each peer has four paths, for example.
- One Phase 2 definition for each Phase 1 configuration.
- One static route for each IPsec interface, with different distance values to prioritize the routes.
- Two Accept security policies per IPsec interface, one for each direction of traffic.
- Dead peer detection enabled in each Phase 1 definition.

The procedures in this section assume that two separate interfaces to the Internet are available on each VPN peer.

Configuring the VPN peers - route-based VPN

VPN peers are configured using Interface Mode for redundant tunnels.

Configure each VPN peer as follows:

1. Ensure that the interfaces used in the VPN have static IP addresses.
2. Create a Phase 1 configuration for each of the paths between the peers.
3. Enable dead peer detection so that one of the other paths is activated if this path fails.
4. Enter these settings in particular, and any other VPN settings as required:

Path 1

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the primary interface of the remote peer.
Local Interface	Select the primary public interface of this peer.
Dead Peer Detection	Enable

Path 2

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the secondary interface of the remote peer.
Local Interface	Select the primary public interface of this peer.
Dead Peer Detection	Enable

Path 3

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the primary interface of the remote peer.
Local Interface	Select the secondary public interface of this peer.
Dead Peer Detection	Enable

Path 4

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the secondary interface of the remote peer.
Local Interface	Select the secondary public interface of this peer.
Dead Peer Detection	Enable

For more information, see [Phase 1 parameters on page 1655](#).

5. Create a Phase 2 definition for each path. See [Phase 2 parameters on page 1675](#). Select the Phase 1 configuration (virtual IPsec interface) that you defined for this path. You can select the name from the Static IP Address part of the list.
6. Create a route for each path to the other peer. If there are two ports on each peer, there are four possible paths between the peer devices.

Destination IP/Mask	The IP address and netmask of the private network behind the remote peer.
Device	One of the virtual IPsec interfaces on the local peer.
Distance	For each path, enter a different value to prioritize the paths.

7. Define the security policy for the local primary interface. See [Defining VPN security policies on page 1](#). You need to create two policies for each path to enable communication in both directions. Enter these settings in particular:

Incoming Interface	Select the local interface to the internal (private) network.
Source Address	All
Outgoing Interface	Select one of the virtual IPsec interfaces you created in Step 2.
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

8. Select **Create New**, leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**, and enter these settings:

Incoming Interface	Select one of the virtual IPsec interfaces you created in Step 2.
Source Address	All
Outgoing Interface	Select the local interface to the internal (private) network.
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

9. Place the policy in the policy list above any other policies having similar source and destination addresses.
10. Repeat this procedure at the remote FortiGate unit.

Creating a backup IPsec interface

You can configure a route-based VPN that acts as a backup facility to another VPN. It is used only while your main VPN is out of service. This is desirable when the redundant VPN uses a more expensive facility.

You can configure a backup IPsec interface only in the CLI. The backup feature works only on interfaces with static addresses that have dead peer detection enabled. The `monitor` option creates a backup VPN for the specified Phase 1 configuration.

In the following example, `backup_vpn` is a backup for `main_vpn`.

```
config vpn ipsec phase1-interface
  edit main_vpn
    set dpd on
    set interface port1
    set nattraversal enable
    set psksecret "hard-to-guess"
    set remote-gw 192.168.10.8
    set type static
  end
  edit backup_vpn
    set dpd on
    set interface port2
    set monitor main_vpn
    set nattraversal enable
    set psksecret "hard-to-guess"
    set remote-gw 192.168.10.8
    set type static
  end
```

IPsec VPN tunnel aggregate interfaces

This feature allows per-packet routing decisions to be made over two or more IPsec tunnel interfaces, which is usually configured to allow WAN connections to terminate at a data center so that redundancy and load-sharing can be built into this new interface.

The new virtual interface can bond/aggregate IPsec devices and have the new device do round-robin distribution, among other algorithms.

Syntax

```
config vpn ipsec phase1-interface
  edit <name>
    set interface wan1
    set gateway ...
    ...
  next
  edit <name>
    set interface wan2
    set gateway ...
    ...
  next
end
config vpn ipsec phase2-interface
  ...
end
config system interface
```

```
edit ipsec-bond
    set type tun-agg
    set member isp1 isp2
next
end
config router static
edit <value>
    set dst <address>
    set device ipsec-bond
next
end
```

Transparent mode VPNs

This section describes transparent VPN configurations, in which two FortiGate units create a VPN tunnel between two separate private networks transparently.

The following topics are included in this section:

Configuration overview

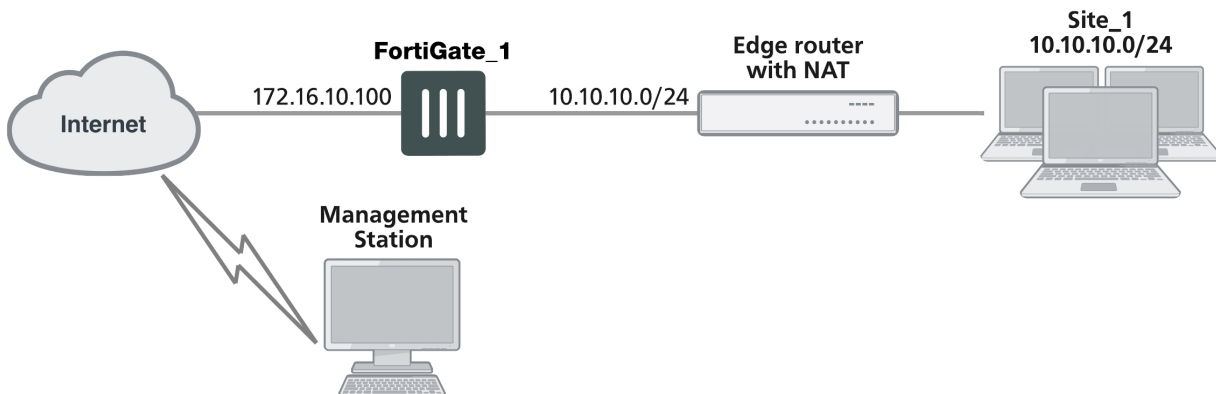

In transparent mode, all interfaces of the FortiGate unit except the management interface (which by default is assigned IP address 10.10.10.1/255.255.255.0) are invisible at the network layer. Typically, when a FortiGate unit runs in transparent mode, different network segments are connected to the FortiGate interfaces. The figure below shows the management station on the same subnet. The management station can connect to the FortiGate unit directly through the web-based manager.

Management station on internal network

An edge router typically provides a public connection to the Internet and one interface of the FortiGate unit is connected to the router. If the FortiGate unit is managed from an external address (see the figure below), the router must translate (NAT) a routable address to direct management traffic to the FortiGate management interface.

Management station on external network

In a transparent VPN configuration, two FortiGate units create a VPN tunnel between two separate private networks transparently. All traffic between the two networks is encrypted and protected by FortiGate security policies.

Both FortiGate units may be running in transparent mode, or one could be running in transparent mode and the other running in NAT mode. If the remote peer is running in NAT mode, it must have a static public IP address.

VPNs between two FortiGate units running in transparent mode do not support inbound/outbound NAT (supported through CLI commands) within the tunnel. In addition, a FortiGate unit running in transparent mode cannot be used in a hub-and-spoke configuration.

Encrypted packets from the remote VPN peer are addressed to the management interface of the local FortiGate unit. If the local FortiGate unit can reach the VPN peer locally, a static route to the VPN peer must be added to the routing table on the local FortiGate unit. If the VPN peer connects through the Internet, encrypted packets from the local FortiGate unit must be routed to the edge router instead. For information about how to add a static route to the FortiGate routing table, see the Advanced Routing Guide.

In the example configuration shown above, Network Address Translation (NAT) is enabled on the router. When an encrypted packet from the remote VPN peer arrives at the router through the Internet, the router performs inbound NAT and forwards the packet to the FortiGate unit. Refer to the software supplier's documentation to configure the router.

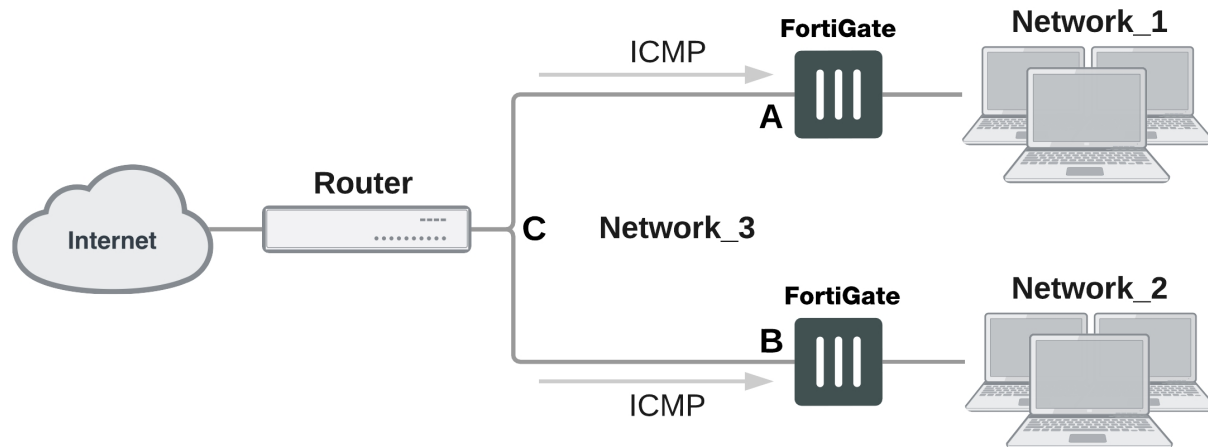

If you want to configure a VPN between two FortiGate units running in transparent mode, each unit must have an independent connection to a router that acts as a gateway to the Internet, and both units must be on separate networks that have a different address space. When the two networks linked by the VPN tunnel have different address spaces (see the figure below), at least one router must separate the two FortiGate units, unless the packets can be redirected using ICMP (as shown in the following figure).

Link between two FortiGate units in transparent mode

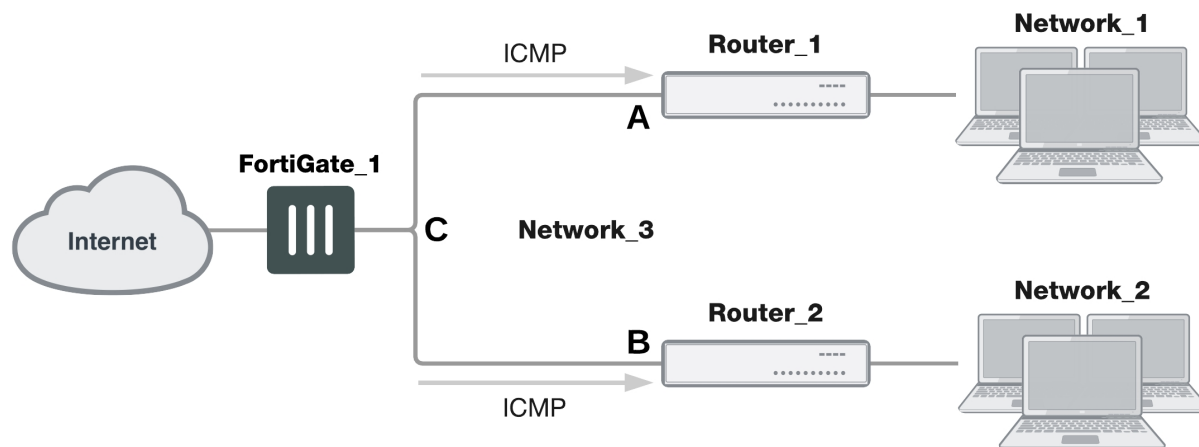

In the figure below, interface C behind the router is the default gateway for both FortiGate units. Packets that cannot be delivered on Network_1 are routed to interface C by default. Similarly, packets that cannot be delivered on Network_2 are routed to interface C. In this case, the router must be configured to redirect packets destined for Network_1 to interface A and redirect packets destined for Network_2 to interface B.

ICMP redirecting packets to two FortiGate units in transparent mode

If there are additional routers behind the FortiGate unit (see the figure below) and the destination IP address of an inbound packet is on a network behind one of those routers, the FortiGate routing table must include routes to those networks. For example, in the following figure, the FortiGate unit must be configured with static routes to interfaces A and B in order to forward packets to Network_1 and Network_2 respectively.

Destinations on remote networks behind internal routers

Transparent VPN infrastructure requirements

- The local FortiGate unit must be operating in transparent mode.
- The management IP address of the local FortiGate unit specifies the local VPN gateway. The management IP address is considered a static IP address for the local VPN peer.
- If the local FortiGate unit is managed through the Internet, or if the VPN peer connects through the Internet, the edge router must be configured to perform inbound NAT and forward management traffic and/or encrypted packets to the FortiGate unit.
- If the remote peer is operating in NAT mode, it must have a static public IP address.

A FortiGate unit operating in transparent mode requires the following basic configuration to operate as a node on the IP network:

- The unit must have sufficient routing information to reach the management station.
- For any traffic to reach external destinations, a default static route to an edge router that forwards packets to the Internet must be present in the FortiGate routing table.
- When all of the destinations are located on the external network, the FortiGate unit may route packets using a single default static route. If the network topology is more complex, one or more static routes in addition to the default static route may be required in the FortiGate routing table.

Only policy-based VPN configurations are possible in transparent mode.

Before you begin

An IPsec VPN definition links a gateway with a tunnel and an IPsec policy. If your network topology includes more than one virtual domain, you must choose components that were created in the same virtual domain. Therefore, before you define a transparent VPN configuration, choose an appropriate virtual domain in which to create the required interfaces, security policies, and VPN components. For more information, see the [Virtual Domains](#) guide.

Configuring the VPN peers

1. The local VPN peer need to operate in transparent mode.
To determine if your FortiGate unit is in transparent mode, go to the **Dashboard > System Information** widget. Select **[change]**. Select transparent for the **Operation Mode**. Two new fields will appear to enter the **Management IP/Netmask**, and the **Default Gateway**.
In transparent mode, the FortiGate unit is invisible to the network. All of its interfaces are on the same subnet and share the same IP address. You only have to configure a management IP address so that you can make configuration changes.

The remote VPN peer may operate in NAT mode or transparent mode.

2. At the local FortiGate unit, define the Phase 1 parameters needed to establish a secure connection with the remote peer. See [Phase 1 parameters on page 1655](#). Select **Advanced** and enter these settings in particular:

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the public interface to the remote peer. If the remote peer is a FortiGate unit running in transparent mode, type the IP address of the remote management interface.
Advanced	Select Nat-traversal , and type a value into the Keepalive Frequency field. These settings protect the headers of encrypted packets from being altered by external NAT devices and ensure that NAT address mappings do not change while the VPN tunnel is open. For more information, see Phase 1 parameters on page 1655 and Phase 1 parameters on page 1655 .

3. Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. See [Phase 2 parameters on page 1675](#). Select the set of Phase 1 parameters that you defined for the remote peer. The name of the remote peer can be selected from the **Static IP Address** list.
4. Define the source and destination addresses of the IP packets that are to be transported through the VPN tunnel. See [Defining VPN security policies on page 1](#). Enter these settings in particular:

- For the originating address (source address), enter the IP address and netmask of the private network behind the local peer network. For the management interface, for example, 10.10.10.0/24. This address needs to be a range to allow traffic from your network through the tunnel. Optionally select `any` for this address.
 - For the remote address (destination address), enter the IP address and netmask of the private network behind the remote peer (for example, 192.168.10.0/24). If the remote peer is a FortiGate unit running in transparent mode, enter the IP address of the remote management interface instead.
5. Define an IPsec security policy to permit communications between the source and destination addresses. See [Defining VPN security policies on page 1](#). Enter these settings in particular:

Incoming Interface	Select the local interface to the internal (private) network.
Source Address	Select the source address that you defined in Step 4.
Outgoing Interface	Select the interface to the edge router. When you configure the IPsec security policy on a remote peer that operates in NAT mode, you select the public interface to the external (public) network instead.
Destination Address	Select the destination address that you defined in Step 4.
VPN Tunnel	<p>Select Use Existing and select the name of the Phase 2 tunnel configuration that you created in Step 3 from the drop-down list.</p> <p>Select Allow traffic to be initiated from the remote site to enable traffic from the remote network to initiate the tunnel.</p>

6. Place the policy in the policy list above any other policies having similar source and destination addresses.
7. Define another IPsec security policy to permit communications between the source and destination addresses in the opposite direction. This security policy and the previous one form a bi-directional policy pair. See [Defining VPN security policies on page 1](#). Enter these settings in particular:

Incoming Interface	Select the interface to the edge router. When you configure the IPsec security policy on a remote peer that operates in NAT mode, you select the public interface to the external (public) network instead.
Source Address	Select the destination address that you defined in Step 4..
Outgoing Interface	Select the local interface to the internal (private) network.
Destination Address	Select the source address that you defined in Step 4.
VPN Tunnel	<p>Select Use Existing and select the name of the Phase 2 tunnel configuration that you created in Step 3 from the drop-down list.</p> <p>Select Allow traffic to be initiated from the remote site to enable traffic from the remote network to initiate the tunnel.</p>

8. Repeat this procedure at the remote FortiGate unit to create bidirectional security policies. Use the local interface and address information local to the remote FortiGate unit.

For more information on transparent mode, see the [System Administration Guide](#).

IPv6 IPsec VPNs

This chapter describes how to configure your FortiGate unit's IPv6 IPsec VPN functionality.

By default IPv6 configurations do not appear on the Web-based Manager. You need to enable the feature first.

To enable IPv6

1. Go to **System > Feature Visibility**.
2. Enable **IPv6**.
3. Select **Apply**.

The following topics are included in this section:

IPv6 IPsec support

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes how IPv6 IPsec support differs from IPv4 IPsec support. FortiOS 4.0 MR3 is IPv6 Ready Logo Program Phase 2 certified.

Where both the gateways and the protected networks use IPv6 addresses, sometimes called IPv6 over IPv6, you can create either an auto-keyed or manually-keyed VPN. You can combine IPv6 and IPv4 addressing in an auto-keyed VPN in the following ways:

IPv4 over IPv6	The VPN gateways have IPv6 addresses. The protected networks have IPv4 addresses. The Phase 2 configurations at either end use IPv4 selectors.
IPv6 over IPv4	The VPN gateways have IPv4 addresses. The protected networks use IPv6 addresses. The Phase 2 configurations at either end use IPv6 selectors.

Compared with IPv4 IPsec VPN functionality, there are some limitations:

- Except for IPv6 over IPv4, remote gateways with Dynamic DNS are not supported.
- Selectors cannot be firewall address names. Only IP address, address range and subnet are supported.
- Redundant IPv6 tunnels are not supported.

Certificates

On a VPN with IPv6 Phase 1 configuration, you can authenticate using VPN certificates in which the common name (cn) is an IPv6 address. The `cn-type` keyword of the `user peer` command has an option, `ipv6`, to support this.

Configuration examples

This section consists of the following configuration examples:

- Site-to-site IPv6 over IPv6 VPN example
- Site-to-site IPv6 over IPv4 VPN example
- Site-to-site IPv4 over IPv6 VPN example

Site-to-site IPv6 over IPv6 VPN example

In this example, computers on IPv6-addressed private networks communicate securely over public IPv6 infrastructure.

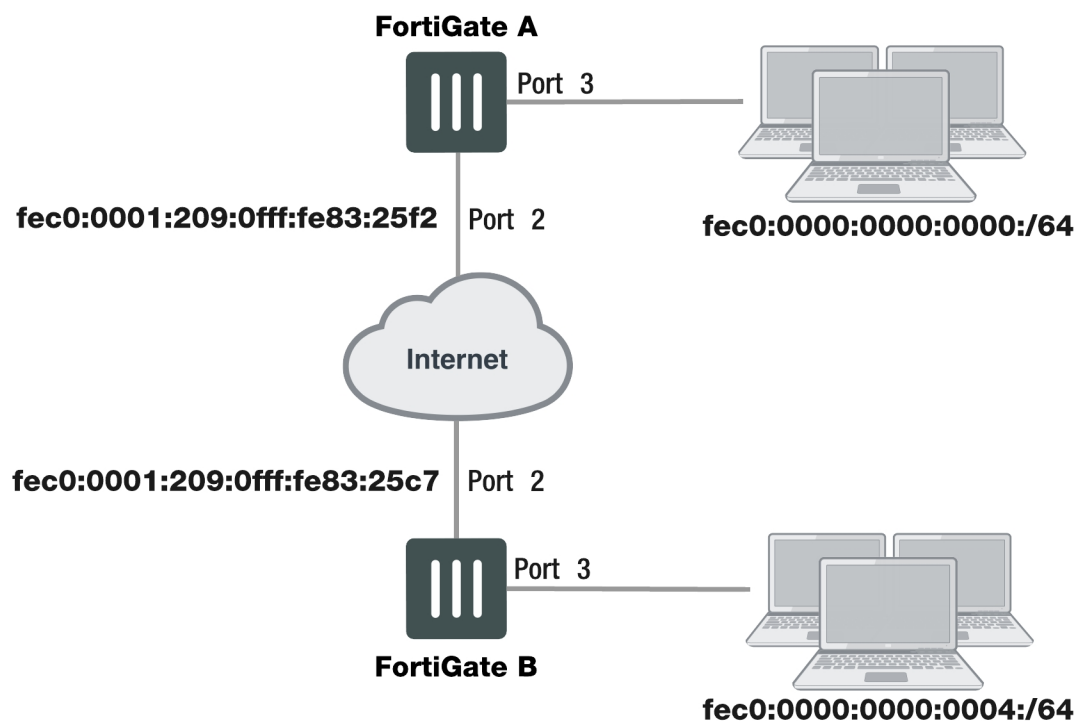

By default IPv6 configurations do not appear on the Web-based Manager. You need to enable the feature first.

To enable IPv6

1. Go to **System > Feature Visibility**.
2. Enable **IPv6**.
3. Select **Apply**.

Example IPv6-over-IPv6 VPN topology

Configure FortiGate A interfaces

Port 2 connects to the public network and port 3 connects to the local network.

```

config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f2/64
    end
  next
  edit port3
    config ipv6
      set ip6-address fec0::0000:209:0fff:fe83:25f3/64
    end
  next
end

```

Configure FortiGate A IPsec settings

The Phase 1 configuration creates a virtual IPsec interface on port 2 and sets the remote gateway to the public IP address FortiGate B. This configuration is the same as for an IPv4 route-based VPN, except that `ip-version` is set to 6 and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address.

```

config vpn ipsec phase1-interface
  edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd [disable | on-idle | on-demand]
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end

```

By default, Phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, `:::/0` for IPv6.

```

config vpn ipsec phase2-interface
  edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end

```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. The address `all6` must be defined using the `firewall address6` command as `::/0`.

```

config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  end

```

```

next
edit 2
    set srcintf toB
    set dstintf port3
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
end

```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB. A default route sends all IPv6 traffic out on port2.

```

config router static6
    edit 1
        set device port2
        set dst 0::/0
    next
    edit 2
        set device toB
        set dst fec0:0000:0000:0004::/64
    end
end

```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. Security policies enable traffic to pass between the private network and the IPsec interface. Routing ensures traffic for the private network behind FortiGate A goes through the VPN and that all IPv6 packets are routed to the public network.

```

config system interface
    edit port2
        config ipv6
            set ip6-address fec0::0003:209:0fff:fe83:25c7/64
        end
    next
    edit port3
        config ipv6
            set ip6-address fec0::0004:209:0fff:fe83:2569/64
        end
    end
end
config vpn ipsec phase1-interface
    edit toA
        set ip-version 6
        set interface port2
        set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
        set dpd [disable | on-idle | on-demand]
        set psksecret maryhadalittlelamb
        set proposal 3des-md5 3des-sha1
    end
end
config vpn ipsec phase2-interface
    edit toA2
        set phase1name toA
        set proposal 3des-md5 3des-sha1
    end
end

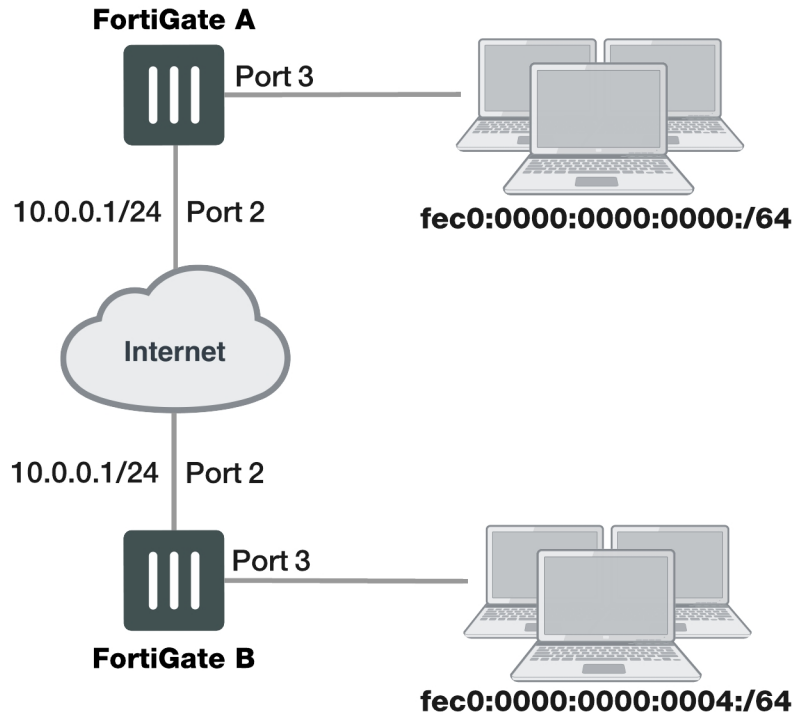

```

```
        set pfs enable
        set replay enable
        set src-addr-type subnet6
        set dst-addr-type subnet6
    end
config firewall policy6
    edit 1
        set srcintf port3
        set dstintf toA
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ANY
        set schedule always
    next
    edit 2
        set srcintf toA
        set dstintf port3
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ANY
        set schedule always
    end
config router static6
    edit 1
        set device port2
        set dst 0::/0
    next
    edit 2
        set device toA
        set dst fec0:0000:0000:0000::/64
end
```

Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed private networks communicate securely over IPv4 public infrastructure.

Example IPv6-over-IPv4 VPN topology**Configure FortiGate A interfaces**

Port 2 connects to the IPv4 public network and port 3 connects to the IPv6 LAN.

```
config system interface
  edit port2
    set 10.0.0.1/24
  next
  edit port3
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f3/64
    end
  end
```

Configure FortiGate A IPsec settings

The Phase 1 configuration uses IPv4 addressing.

```
config vpn ipsec phase1-interface
  edit toB
    set interface port2
    set remote-gw 10.0.1.1
    set dpd [disable | on-idle | on-demand]
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

The Phase 2 configuration uses IPv6 selectors. By default, Phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are `0.0.0.0/0` for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
edit toB2
set phase1name toB
set proposal 3des-md5 3des-sha1
set pfs enable
set replay enable
set src-addr-type subnet6
set dst-addr-type subnet6
end
```

Configure FortiGate A security policies

IPv6 security policies are required to allow traffic between `port3` and the IPsec interface `toB` in each direction. Define the address `all6` using the `firewall address6` command as `::/0`.

```
config firewall policy6
edit 1
set srcintf port3
set dstintf toB
set srcaddr all6
set dstaddr all6
set action accept
set service ANY
set schedule always
next
edit 2
set srcintf toB
set dstintf port3
set srcaddr all6
set dstaddr all6
set action accept
set service ANY
set schedule always
end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface `toB` using an IPv6 static route. A default route sends all IPv4 traffic, including the IPv4 IPsec packets, out on `port2`.

```
config router static6
edit 1
set device toB
set dst fec0:0000:0000:0004::/64
end
config router static
edit 1
set device port2
set dst 0.0.0.0/0
set gateway 10.0.0.254
end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the IPv4 public IP address of FortiGate A. The IPsec Phase 2 configuration has IPv6 selectors.

IPv6 security policies enable traffic to pass between the private network and the IPsec interface. An IPv6 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv4 static route ensures that all IPv4 packets are routed to the public network.

```
config system interface
  edit port2
    set 10.0.1.1/24
  next
  edit port3
    config ipv6
      set ip6-address fec0::0004:209:0fff:fe83:2569/64
    end
config vpn ipsec phase1-interface
  edit toA
    set interface port2
    set remote-gw 10.0.0.1
    set dpd [disable | on-idle | on-demand]
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-shal
  end
config vpn ipsec phase2-interface
  edit toA2
    set phase1name toA
    set proposal 3des-md5 3des-shal
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end
config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toA
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  next
  edit 2
    set srcintf toA
    set dstintf port3
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  end
config router static6
  edit 1
```

```

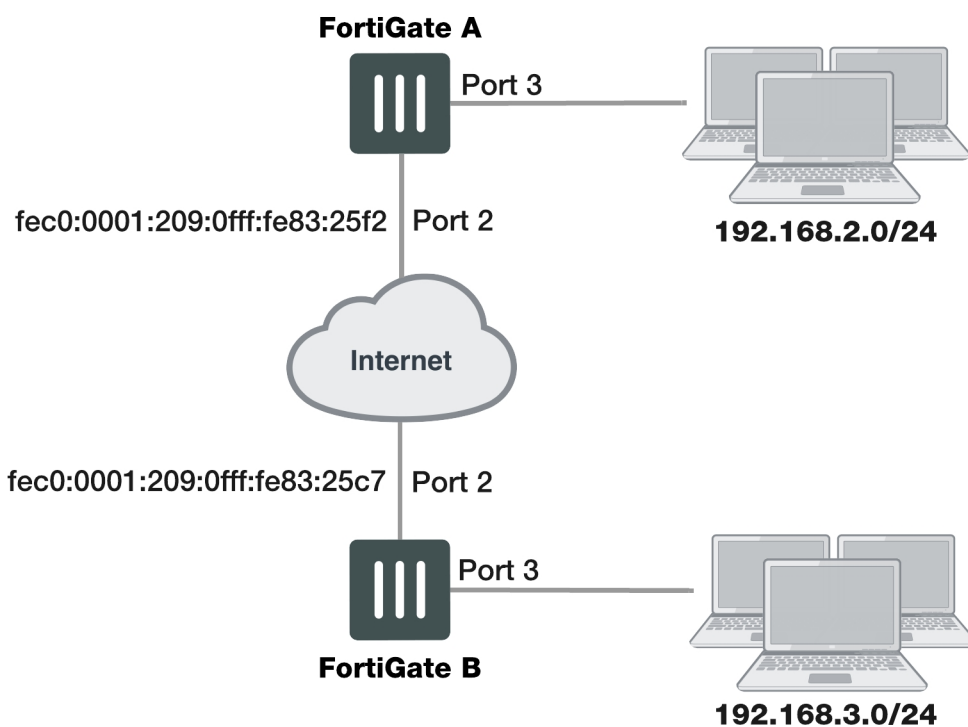

set device toA
set dst fec0:0000:0000:0000::/64
end
config router static
edit 1
set device port2
set gateway 10.0.1.254
end

```

Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

Example IPv4-over-IPv6 VPN topology

Configure FortiGate A interfaces

Port 2 connects to the IPv6 public network and port 3 connects to the IPv4 LAN.

```

config system interface
edit port2
config ipv6
set ip6-address fec0::0001:209:0fff:fe83:25f2/64
end
next
edit port3
set 192.168.2.1/24
end

```

Configure FortiGate A IPsec settings

The Phase 1 configuration is the same as in the IPv6 over IPv6 example.

```
config vpn ipsec phase1-interface
  edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd [disable | on-idle | on-demand]
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

The Phase 2 configuration is the same as you would use for an IPv4 VPN. By default, Phase 2 selectors are set to accept all subnet addresses for source and destination.

```
config vpn ipsec phase2-interface
  edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
  end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. These are IPv4 security policies.

```
config firewall policy
  edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  next
  edit 2
    set srcintf toB
    set dstintf port3
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv4 static route. A default route sends all IPv6 traffic, including the IPv6 IPsec packets, out on port2.

```
config router static6
```

```

edit 1
    set device port2
    set dst 0::/0
next
edit 2
    set device toB
    set dst 192.168.3.0/24
end

```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. The IPsec Phase 2 configuration has IPv4 selectors.

IPv4 security policies enable traffic to pass between the private network and the IPsec interface. An IPv4 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv6 static route ensures that all IPv6 packets are routed to the public network.

```

config system interface
    edit port2
        config ipv6
            set ip6-address fec0::0003:fe83:25c7/64
        end
    next
    edit port3
        set 192.168.3.1/24
    end
config vpn ipsec phase1-interface
    edit toA
        set ip-version 6
        set interface port2
        set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
        set dpd [disable | on-idle | on-demand]
        set psksecret maryhadalittlelamb
        set proposal 3des-md5 3des-sha1
    end
config vpn ipsec phase2-interface
    edit toA2
        set phaselname toA
        set proposal 3des-md5 3des-sha1
        set pfs enable
        set replay enable
    end
config firewall policy
    edit 1
        set srcintf port3
        set dstintf toA
        set srcaddr all
        set dstaddr all
        set action accept
        set service ANY
        set schedule always
    next
    edit 2
        set srcintf toA
        set dstintf port3

```

```
        set srcaddr all
        set dstaddr all
        set action accept
        set service ANY
        set schedule always
    end
config router static6
    edit 1
        set device port2
        set dst 0::/0
    next
    edit 2
        set device toA
        set dst 192.168.2.0/24
    end
```

L2TP and IPsec (Microsoft VPN)

This section describes how to set up a VPN that is compatible with the Microsoft Windows native VPN, which is Layer 2 Tunneling Protocol (L2TP) with IPsec encryption.

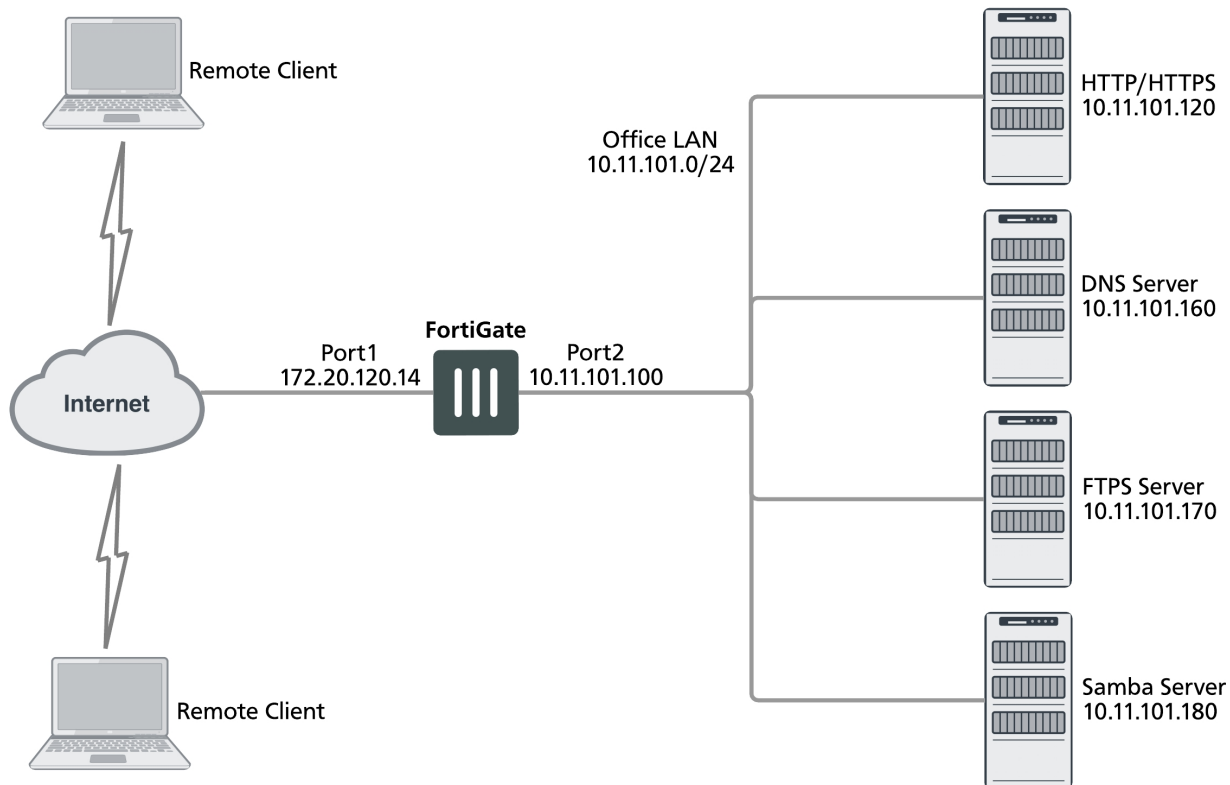

The following topics are included in this section:

For troubleshooting information, refer to [Troubleshooting L2TP and IPsec](#).

Overview

The topology of a VPN for Microsoft Windows dialup clients is very similar to the topology for FortiClient Endpoint Security clients.

Example FortiGate VPN configuration with Microsoft clients

For users, the difference is that instead of installing and using the FortiClient application, they configure a network connection using the software built into the Microsoft Windows operating system. Starting in FortiOS 4.0 MR2, you can configure a FortiGate unit to work with unmodified Microsoft VPN client software.

Layer 2 Tunneling Protocol (L2TP)

L2TP is a tunneling protocol published in 1999 that is used with VPNs, as the name suggests. Microsoft Windows operating system has a built-in L2TP client starting since Windows 2000. Mac OS X 10.3 system and higher also have a built-in client.

L2TP provides no encryption and used UDP port 1701. IPsec is used to secure L2TP packets. The initiator of the L2TP tunnel is called the L2TP Access Concentrator (LAC).

L2TP and IPsec is supported for native Windows XP, Windows Vista and Mac OSX native VPN clients. However, in Mac OSX (OSX 10.6.3, including patch releases) the L2TP feature does not work properly on the Mac OS side.

Assumptions

The following assumptions have been made for this example:

- L2TP protocol traffic is allowed through network firewalls (TCP and UDP port 1701)
- User has Microsoft Windows 2000 or higher — a Windows version that supports L2TP

Configuration overview

The following section consists of configuring the FortiGate unit and configuring the Windows PC.

Configuring the FortiGate unit

To configure the FortiGate unit, you must:

- Configure L2TP users and firewall user group.
- Configure the L2TP VPN, including the IP address range it assigns to clients.
- Configure an IPsec VPN with encryption and authentication settings that match the Microsoft VPN client.
- Configure security policies.

Configuring L2TP users and firewall user group

Remote users must be authenticated before they can request services and/or access network resources through the VPN. The authentication process can use a password defined on the FortiGate unit or an established external authentication mechanism such as RADIUS or LDAP.

Creating user accounts

You need to create user accounts and then add these users to a firewall user group to be used for L2TP authentication. The Microsoft VPN client can automatically send the user's Windows network logon credentials. You might want to use these for their L2TP user name and password.

Creating a user account - web-based manager

1. Go to **User & Device > User Definition** and select **Create New**.
2. Enter the **User Name**.
3. Do one of the following:

- Select **Password** and enter the user's assigned password.
- Select **Match user on LDAP server**, **Match user on RADIUS server**, or **Match user on TACACS+ server** and select the authentication server from the list. The authentication server must be already configured on the FortiGate unit.

4. Select **OK**.

Creating a user account - CLI

To create a user account called `user1` with the password `123_user`, enter:

```
config user local
  edit user1
    set type password
    set passwd "123_user"
    set status enable
  end
```

Creating a user group

When clients connect using the L2TP-over-IPsec VPN, the FortiGate unit checks their credentials against the user group you specify for L2TP authentication. You need to create a firewall user group to use for this purpose.

Creating a user group - web-based manager

1. Go to **User & Device > User Groups**, select **Create New**, and enter the following:

Name	Type or edit the user group name (for example, <code>L2TP_group</code>).
Type	Select Firewall .
Available Users/Groups	The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, or PKI users that can be added to the user group. To add a member to this list, select the name and then select the right arrow button.
Members	The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, or PKI users that belong to the user group. To remove a member, select the name and then select the left arrow button.

2. Select **OK**.

Creating a user group - CLI

To create the user group `L2TP_group` and add members `User_1`, `User_2`, and `User_3`, enter:

```
config user group
  edit L2TP_group
    set group-type firewall
    set member User_1 User_2 User_3
  end
```

Configuring L2TP

You can only configure L2TP settings in the CLI. As well as enabling L2TP, you set the range of IP address values that are assigned to L2TP clients and specify the user group that can access the VPN. For example, to allow

access to users in the L2TP_group and assign them addresses in the range 192.168.0.50 to 192.168.0.59, enter:

```
config vpn l2tp
  set sip 192.168.0.50
  set eip 192.168.0.59
  set status enable
  set usrgroup "L2TP_group"
end
```

One of the security policies for the L2TP over IPsec VPN uses the client address range, so you need also need to create a firewall address for that range. For example,

```
config firewall address
  edit L2TPclients
    set type iprange
    set start-ip 192.168.0.50
    set end-ip 192.168.0.59
  end
```

Alternatively, you could define this range in the web-based manager.

Configuring IPsec

The Microsoft VPN client uses IPsec for encryption. The configuration needed on the FortiGate unit is the same as for any other IPsec VPN with the following exceptions.

- Transport mode is used instead of tunnel mode.
- The encryption and authentication proposals must be compatible with the Microsoft client.

Whether Transport mode is *required* depends on the configuration of the peer device (typically an old Windows device, since newer versions of Windows don't require IPsec and L2TP—they can run IPsec natively).

When configuring L2TP, do not name the VPN "L2TP" as that will result in a conflict.

L2TP over IPsec is supported on the FortiGate unit for both policy-based and route-based configurations, but the following example is policy-based.

Configuring Phase 1 - web-based manager

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).

Name	Enter a name for this VPN, dialup_p1 for example.
Remote Gateway	Dialup User
Local Interface	Select the network interface that connects to the Internet. For example, port1.

Mode	Main (ID protection)
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key. This key must also be entered in the Microsoft VPN client.
Advanced	Select Advanced to enter the following information.
Phase 1 Proposal	Enter the following Encryption/Authentication pairs: AES256-MD5, 3DES-SHA1, AES192-SHA1
Diffie-Hellman Group	2
NAT Traversal	Enable
Dead Peer Detection	Enable

Configuring Phase 1 - CLI

To create a Phase 1 configuration called dialup_p1 on a FortiGate unit that has port1 connected to the Internet, you would enter:

```
config vpn ipsec phase1
  edit dialup_p1
    set type dynamic
    set interface port1
    set mode main
    set psksecret *****
    set proposal aes256-md5 3des-sha1 aes192-sha1
    set dhgrp 2
    set natTraversal enable
    set dpd [disable | on-idle | on-demand]
  end
```

It is worth noting here that the command `config vpn ipsec phase1` is used rather than `config vpn ipsec phase1-interface` because this configuration is policy-based and not route-based.

Configuring Phase 2 - web-based manager

1. Open the **Phase 2 Selectors** panel.
2. Enter the following information and then select **OK**.

Phase 2 Proposal	Enter the following Encryption/Authentication pairs: AES256-MD5, 3DES-SHA1, AES192-SHA1
Enable replay detection	Enable
Enable perfect forward secrecy (PFS)	Disable

Keylife	3600 seconds
----------------	--------------

3. Make this a transport-mode VPN. You must use the CLI to do this. If your Phase 2 name is dialup_p2, you would enter:

```
config vpn ipsec phase2
  edit dialup_p2
    set encapsulation transport-mode
  end
```

Configuring Phase 2 - CLI

To configure a Phase 2 to work with your phase_1 configuration, you would enter:

```
config vpn ipsec phase2
  edit dialup_p2
    set phase1name dialup_p1
    set proposal aes256-md5 3des-sha1 aes192-sha1
    set replay enable
    set pfs disable
    set keylifeseconds 3600
    set encapsulation transport-mode
  end
```

Once again, note here that the command `config vpn ipsec phase2` is used rather than `config vpn ipsec phase2-interface` because this configuration is policy-based and not route-based.

Configuring security policies

The security policies required for L2TP over IPsec VPN are:

- An IPsec policy, as you would create for any policy-based IPsec VPN
- A regular ACCEPT policy to allow traffic from the L2TP clients to access the protected network

Configuring the IPsec security policy - web-based manager

1. Go to **System > Feature Visibility** and enable **Policy-based IPsec VPN**.
2. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
3. Set the **Action** to **IPsec** and enter the following information:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	All
Outgoing Interface	Select the FortiGate unit's public interface.
Destination Address	All

VPN Tunnel	Select Use Existing and select the name of the Phase 1 configuration that you created. For example, dialup_p1. See Configuring IPsec on page 1789 .
Allow traffic to be initiated from the remote site	enable

4. Select **OK**.

Configuring the IPsec security policy - CLI

If your VPN tunnel (Phase 1) is called dialup_p1, your protected network is on port2, and your public interface is port1, you would enter:

```
config firewall policy
edit 0
set srcintf port2
set dstintf port1
set srcaddr all
set dstaddr all
set action ipsec
set schedule always
set service all
set inbound enable
set vpngateway dialup_p1
end
```

Configuring the ACCEPT security policy - web-based manager

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information and select **OK**:

Incoming Interface	Select the FortiGate unit's public interface.
Source Address	Select the firewall address that you defined for the L2TP clients.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address	All
Action	ACCEPT

Configuring the ACCEPT security policy - CLI

If your public interface is port1, your protected network is on port2, and L2TPclients is the address range that L2TP clients use, you would enter:

```
config firewall policy
edit 1
set srcintf port1
set dstintf port2
set srcaddr L2TPclients
set dstaddr all
```

```
set action accept
set schedule always
set service all
end
```

Configuring the Windows PC

Configuration of the Windows PC for a VPN connection to the FortiGate unit consists of the following:

1. In Network Connections, configure a Virtual Private Network connection to the FortiGate unit.
2. Ensure that the IPSEC service is running.
3. Ensure that IPsec has not been disabled for the VPN client. It may have been disabled to make the Microsoft VPN compatible with an earlier version of FortiOS.

The instructions in this section are based on Windows XP. Other versions of Windows may vary slightly.

Configuring the network connection

1. Open **Network Connections**.
This is available through the Control Panel.
2. Double-click **New Connection Wizard** and **Select Next**.
3. Select **Connect to the network at my workplace**.
4. Select **Next**.
5. Select **Virtual Private Network connection** and select **Next**.
6. In the **Company Name** field, enter a name for the connection and select **Next**.
7. Select **Do not dial the initial connection** and then select **Next**.
8. Enter the public IP address or FQDN of the FortiGate unit and select **Next**.
9. Optionally, select **Add a shortcut to this connection to my desktop**.
10. Select **Finish**.
The **Connect** dialog opens on the desktop.
11. Select **Properties** and then select the **Security** tab.
12. Select **IPsec Settings**.
13. Select **Use pre-shared key for authentication**, enter the preshared key that you configured for your VPN, and select **OK**.
14. Select **OK**.

Checking that the IPsec service is running

1. Open **Administrative Tools** through the Control Panel.
2. Double-click **Services**.
3. Look for IPSEC Services. Confirm that the **Startup Type** is **Automatic** and **Status** is set to **Started**. If needed, double-click **IPsec Services** to change these settings.

Checking that IPsec has not been disabled

1. Select **Start > Run**.
2. Enter regedit and select **OK**.
3. Find the Registry key HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RasMan\Parameters
4. If there is a ProhibitIPsec value, it must be set to 0.

Enforcing IPsec in L2TP configuration

An `enforce-ipsec` option is available in L2TP configuration to force the FortiGate L2TP server to accept only IPsec encrypted connections.

Syntax

```
config vpn l2tp
  set eip 50.0.0.100
  set sip 50.0.0.1
  set status enable
  set enforce-ipsec-interface {disable | enable}      (default = disable)
  set usrgrp <group_name>
end
```

GRE over IPsec (Cisco VPN)

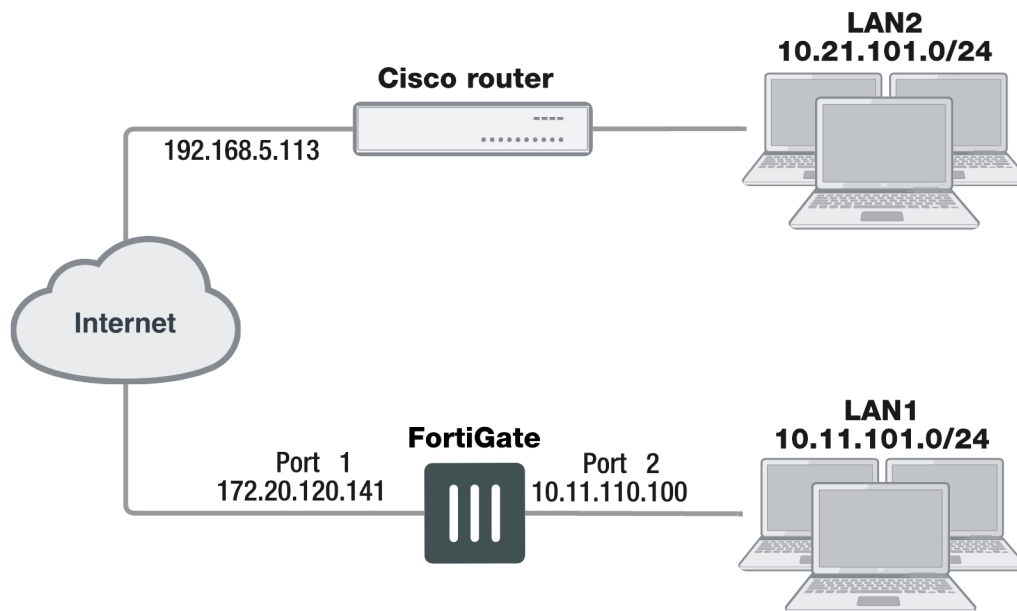

This section describes how to configure a FortiGate VPN that is compatible with Cisco-style VPNs that use GRE in an IPsec tunnel.

The following topics are included in this section:

Cisco products that include VPN support often use Generic Routing Encapsulation (GRE) protocol tunnel over IPsec encryption. This chapter describes how to configure a FortiGate unit to work with this type of Cisco VPN.

Cisco VPNs can use either transport mode or tunnel mode IPsec. Before FortiOS 4.0 MR2, the FortiGate unit was compatible only with tunnel mode IPsec.

Example FortiGate to Cisco GRE-over-IPsec VPN

In this example, users on LAN1 are provided access to LAN2.

Configuration overview

The following section consists of configuring the FortiGate unit and configuring the Cisco router.

Configuring the FortiGate unit

There are several steps to the GRE-over-IPsec configuration:

- Enable overlapping subnets. This is needed because the IPsec and GRE tunnels will use the same addresses.
- Configure a route-based IPsec VPN on the external interface.
- Configure a GRE tunnel on the virtual IPsec interface. Set its local gateway and remote gateway addresses to match the local and remote gateways of the IPsec tunnel.
- Configure security policies to allow traffic to pass in both directions between the GRE virtual interface and the IPsec virtual interface.
- Configure security policies to allow traffic to pass in both directions between the protected network interface and the GRE virtual interface.
- Configure a static route to direct traffic destined for the network behind the Cisco router into the GRE-over-IPsec tunnel.

Enabling overlapping subnets

By default, each FortiGate unit network interface must be on a separate network. The configuration described in this chapter assigns an IPsec tunnel end point and the external interface to the same network. Enable subnet overlap as follows:

```
config system settings
    set allow-subnet-overlap enable
end
```

Configuring the IPsec VPN

A route-based VPN is required. It must use encryption and authentication algorithms compatible with the Cisco equipment to which it connects. In this chapter, preshared key authentication is shown.

Configuring the IPsec VPN - web-based manager

1. Define the Phase 1 configuration needed to establish a secure connection with the remote Cisco device. Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel, tocsico for example. This is the name of the virtual IPsec interface. It appears in Phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select Static IP Address .
IP Address	Enter the IP address of the Cisco device public interface. For example, 192.168.5.113.
Local Interface	Select the FortiGate unit's public interface. For example, 172.20.120.141.

Mode	Select Main (ID Protection) .
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key. It must match the preshared key on the Cisco device.
Advanced	Select the Advanced button to see the following settings.
Phase 1 Proposal	3DES-MD5
	At least one proposal must match the settings on the Cisco unit.

For more information about these settings, see [Phase 1 parameters on page 1655](#).

2. Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. For compatibility with the Cisco router, Quick Mode Selectors must be entered, which includes specifying protocol 47, the GRE protocol. Enter these settings in particular:

Phase 2 Proposal	3DES-MD5
	At least one proposal must match the settings on the Cisco unit.
Quick Mode Selector	
Source Address	Enter the GRE local tunnel end IP address. For example 172.20.120.141.
Source Port	0
Destination Address	Enter the GRE remote tunnel end IP address. For example 192.168.5.113.
Destination Port	0
Protocol	47

For more information about these settings, see [Phase 2 parameters on page 1675](#).

3. If the Cisco device is configured to use transport mode IPsec, you need to use transport mode on the FortiGate VPN. You can configure this only in the CLI. In your Phase 2 configuration, set `encapsulation to transport-mode` as follows:

```
config vpn phase2-interface
  edit to_cisco_p2
    set encapsulation transport-mode
  end
```

Configuring the IPsec VPN - CLI

```
config vpn ipsec phase1-interface
  edit tocisco
    set interface port1
    set proposal 3des-sha1 aes128-sha1
```

```

        set remote-gw 192.168.5.113
        set psksecret xxxxxxxxxxxxxxxxx
    end
config vpn ipsec phase2-interface
edit tocisco_p2
    set phase1name "tocisco"
    set proposal 3des-md5
    set encapsulation tunnel-mode // if tunnel mode
    set encapsulation transport-mode // if transport mode
    set protocol 47
    set src-addr-type ip
    set dst-start-ip 192.168.5.113
    set src-start-ip 172.20.120.141
end

```

Adding IPsec tunnel end addresses

The Cisco configuration requires an address for its end of the IPsec tunnel. The addresses are set to match the GRE gateway addresses. Use the CLI to set the addresses, like this:

```

config system interface
edit tocisco
    set ip 172.20.120.141 255.255.255.255
    set remote-ip 192.168.5.113
end

```

Configuring the GRE tunnel

The GRE tunnel runs between the virtual IPsec public interface on the FortiGate unit and the Cisco router. You must use the CLI to configure a GRE tunnel. In the example, you would enter:

```

config system gre-tunnel
edit gre1
    set interface tocisco
    set local-gw 172.20.120.141
    set remote-gw 192.168.5.113
end

```

`interface` is the virtual IPsec interface, `local-gw` is the FortiGate unit public IP address, and `remote-gw` is the remote Cisco device public IP address

Adding GRE tunnel end addresses

You will also need to add tunnel end addresses. The Cisco router configuration requires an address for its end of the GRE tunnel. Using the CLI, enter tunnel end addresses that are not used elsewhere on the FortiGate unit, like this:

```

config system interface
edit gre1
    set ip 10.0.1.1 255.255.255.255
    set remote-ip 10.0.1.2
end

```

Configuring security policies

Two sets of security policies are required:

- Policies to allow traffic to pass in both directions between the GRE virtual interface and the IPsec virtual interface.
- Policies to allow traffic to pass in both directions between the protected network interface and the GRE virtual interface.

Configuring security policies - web-based manager

1. Define an ACCEPT firewall security policy to permit communications between the protected network and the GRE tunnel:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	All
Outgoing Interface	Select the GRE tunnel virtual interface you configured.
Destination Address	All
Action	ACCEPT
Enable NAT	Disable

2. To permit the remote client to initiate communication, you need to define a firewall address security policy for communication in that direction:

Incoming Interface	Select the GRE tunnel virtual interface you configured.
Source Address	All
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address	All
Action	ACCEPT
Enable NAT	Disable

3. Define a pair of ACCEPT firewall address security policies to permit traffic to flow between the GRE virtual interface and the IPsec virtual interface:

Incoming Interface	Select the GRE virtual interface. See Configuring the GRE tunnel on page 1798 .
Source Address	All
Outgoing Interface	Select the virtual IPsec interface you created. See Configuring the IPsec VPN on page 1796 .
Destination Address	All
Action	ACCEPT
Enable NAT	Disable

Incoming Interface	Select the virtual IPsec interface you created. See Configuring the IPsec VPN on page 1796 .
Source Address	All
Outgoing Interface	Select the GRE virtual interface. See Configuring the GRE tunnel on page 1798 .
Destination Address	All
Action	ACCEPT
Enable NAT	Disable

Configuring security policies - CLI

```

config firewall policy
  edit 1 // LAN to GRE tunnel
    set srcintf port2
    set dstintf gre1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
  edit 2 // GRE tunnel to LAN
    set srcintf gre1
    set dstintf port2
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
  edit 3 // GRE tunnel to IPsec interface
    set srcintf "gre1"
    set dstintf "tocisco"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
  next
  edit 4 // IPsec interface to GRE tunnel
    set srcintf "tocisco"
    set dstintf "gre1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
end

```

Configuring routing

Traffic destined for the network behind the Cisco router must be routed to the GRE tunnel. To do this, create a static route

1. Go to **Network > Static Routes** and select **Create New**.
2. Enter the following information and select **OK**.

Destination IP/Mask	Enter the IP address and netmask for the network behind the Cisco router. For example 10.21.101.0 255.255.255.0.
Device	Select the GRE virtual interface.
Distance (Advanced)	Leave setting at default value.

In the CLI, using the example values, you would enter

```
config router static
edit 0
set device gre1
set dst 10.21.101.0 255.255.255.0
end
```

Changing GRE over GRE tunnel interface attributes

Administrators can change GRE over GRE tunnel attributes, such as assigning an IP address for a specific configuration application, even if the child interface is not an IPsec tunnel interface.

IPv6 support for GRE tunnels

Support is provided for GRE tunnel termination using IPv6 addresses on both ends of the tunnel (similar to IPv4 functionality).

Syntax

```
config system gre-tunnel
edit <name>
set ip-version 6
set remote-gw6 11:1:1::1
set local-gw6 11:1:1::2
...
next
end
```

Configuring the Cisco router

Using Cisco IOS, you would configure the Cisco router as follows, using the addresses from the example:

```
config ter
crypto ipsec transform-set myset esp-3des esp-md5-hmac
no mode
exit
no ip access-list extended tunnel
ip access-list extended tunnel
```

```
permit gre host 192.168.5.113 host 172.20.120.141
exit
interface Tunnel1
ip address 10.0.1.2 255.255.255.0
tunnel source 192.168.5.113
tunnel destination 172.20.120.141
!
ip route 10.11.101.0 255.255.255.0 Tunnel1
end
clear crypto sa
clear crypto isakmp
```

For transport mode, change `no mode to mode transport`.

This is only the portion of the Cisco router configuration that applies to the GRE-over-IPsec tunnel. For more information, refer to the Cisco documentation.

Keep-alive support for GRE

The FortiGate can send a GRE keep-alive response to a Cisco device to detect a GRE tunnel. If it fails, it will remove any routes over the GRE interface.

Syntax

```
config system gre-tunnel
edit <id>
    set keepalive-interval <value: 0-32767>
    set keepalive-failtimes <value: 1-255>
next
end
```

Protecting OSPF with IPsec

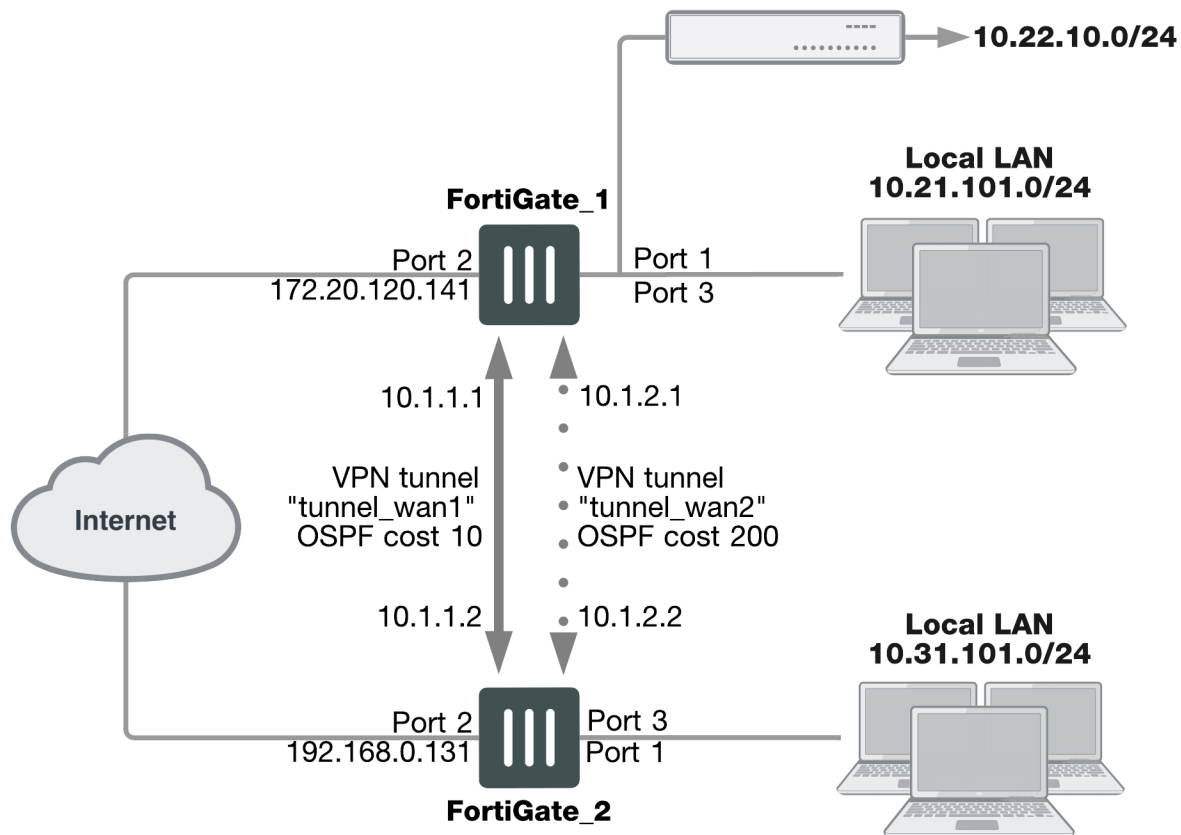

For enhanced security, OSPF dynamic routing can be carried over IPsec VPN links.

The following topics are included in this section:

Configuration overview

This chapter shows an example of OSPF routing conducted over an IPsec tunnel between two FortiGate units. The network shown below is a single OSPF area. FortiGate_1 is an Area border router that advertises a static route to 10.22.10.0/24 in OSPF. FortiGate_2 advertises its local LAN as an OSPF internal route.

OSPF over an IPsec VPN tunnel

The section [Configuration overview](#) describes the configuration with only one IPsec VPN tunnel, tunnel_wan1. Then, the section [Configuration overview](#) describes how you can add a second tunnel to provide a redundant backup path. This is shown above as VPN tunnel "tunnel_wan2".

Only the parts of the configuration concerned with creating the IPsec tunnel and integrating it into the OSPF network are described. It is assumed that security policies are already in place to allow traffic to flow between the interfaces on each FortiGate unit.

OSPF over IPsec configuration

There are several steps to the OSPF-over-IPsec configuration:

- Configure a route-based IPsec VPN on an external interface. It will connect to a corresponding interface on the other FortiGate unit. Define the two tunnel-end addresses.
- Configure a static route to the other FortiGate unit.
- Configure the tunnel network as part of the OSPF network and define the virtual IPsec interface as an OSPF interface.

This section describes the configuration with only one VPN, tunnel_wan1. The other VPN is added in the section [Configuration overview on page 1803](#).

Configuring the IPsec VPN

A route-based VPN is required. In this chapter, preshared key authentication is shown. Certificate authentication is also possible. Both FortiGate units need this configuration.

Configuring Phase 1

1. Define the Phase 1 configuration needed to establish a secure connection with the other FortiGate unit. For more information, see [Phase 1 parameters on page 1655](#).

Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel, tunnel_wan1 for example. This becomes the name of the virtual IPsec interface.
Remote Gateway	Select Static IP Address .
IP Address	Enter the IP address of the other FortiGate unit's public (Port 2) interface.
Local Interface	Select this FortiGate unit's public (Port 2) interface.
Mode	Select Main (ID Protection) .
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key. It must match the preshared key on the other FortiGate unit.
Advanced	Select Advanced .

Assigning the tunnel end IP addresses

1. Go to **Network > Interfaces**, select the virtual IPsec interface that you just created on Port 2 and select **Edit**.
2. In the **IP** and **Remote IP** fields, enter the following tunnel end addresses:

	FortiGate_1	FortiGate_2
IP	10.1.1.1	10.1.1.2
Remote_IP	10.1.1.2	10.1.1.1

These addresses are from a network that is not used for anything else.

Configuring Phase 2

1. Enter a name to identify this Phase 2 configuration, `twan1_p2`, for example.
2. Select the name of the Phase 1 configuration that you defined in Step ["Configuration overview" on page 1803](#), `tunnel_wan1` for example.

Configuring static routing

You need to define the route for traffic leaving the external interface.

1. Go to **Network > Static Routes**, select **Create New**.
2. Enter the following information.

Destination IP/Mask	Leave as 0.0.0.0 0.0.0.0.
Device	Select the external interface.
Gateway	Enter the IP address of the next hop router.

Configuring OSPF

This section does not attempt to explain OSPF router configuration. It focusses on the integration of the IPsec tunnel into the OSPF network. This is accomplished by assigning the tunnel as an OSPF interface, creating an OSPF route to the other FortiGate unit.

This configuration uses loopback interfaces to ease OSPF troubleshooting. The OSPF router ID is set to the loopback interface address. The loopback interface ensures the router is always up. Even though technically the router ID doesn't have to match a valid IP address on the FortiGate unit, having an IP that matches the router ID makes troubleshooting a lot easier.

The two FortiGate units have slightly different configurations. FortiGate_1 is an AS border router that advertises its static default route. FortiGate_2 advertises its local LAN as an OSPF internal route.

Setting the router ID for each FortiGate unit to the lowest possible value is useful if you want the FortiGate units to be the designated router (DR) for their respective ASes. This is the router that broadcasts the updates for the AS.

Leaving the IP address on the OSPF interface at 0.0.0.0 indicates that all potential routes will be advertised, and it will not be limited to any specific subnet. For example if this IP address was 10.1.0.0, then only routes that match that subnet will be advertised through this interface in OSPF.

FortiGate_1 OSPF configuration

When configuring FortiGate_1 for OSPF, the loopback interface is created, and then you configure OSPF area networks and interfaces.

With the exception of creating the loopback interface, OSPF for this example can all be configured in either the web-based manager or CLI.

Creating the loopback interface

A loopback interface can be configured in the CLI only. For example, if the interface will have an IP address of 10.0.0.1, you would enter:

```
config system interface
  edit lback1
    set vdom root
    set ip 10.0.0.1 255.255.255.255
    set type loopback
  end
```

The loopback addresses and corresponding router IDs on the two FortiGate units must be different. For example, set the FortiGate 1 loopback to 10.0.0.1 and the FortiGate 2 loopback to 10.0.0.2.

Configuring OSPF area, networks, and interfaces - web-based manager

1. On FortiGate_1, go to **Network > OSPF**.
2. Enter the following information to define the router, area, and interface information.

Router ID	Enter 10.0.0.1. Select Apply before entering the remaining information.
Advanced Options	
Redistribute	Select the Connected and Static check boxes. Use their default metric values.
Areas	Select Create New , enter the Area and Type and then select OK .
Area	0.0.0.0
Type	Regular
Interfaces	Enter a name for the OSPF interface, ospf_wan1 for example.
Name	
Interface	Select the virtual IPsec interface, tunnel_wan1.
IP	0.0.0.0

3. For **Networks**, select **Create New**.
4. Enter the **IP/Netmask** of 10.1.1.0/255.255.255.0 and an **Area** of 0.0.0.0.
5. For **Networks**, select **Create New**.
6. Enter the **IP/Netmask** of 10.0.0.1/255.255.255.0 and an **Area** of 0.0.0.0.
7. Select **Apply**.

Configuring OSPF area and interfaces - CLI

Your loopback interface is 10.0.0.1, your tunnel ends are on the 10.1.1.0/24 network, and your virtual IPsec interface is named `tunnel_wan1`. Enter the following CLI commands:

```

config router ospf
  set router-id 10.0.0.1
  config area
    edit 0.0.0.0
  end
  config network
    edit 4
      set prefix 10.1.1.0 255.255.255.0
    next
    edit 2
      set prefix 10.0.0.1 255.255.255.255
    end
  config ospf-interface
    edit ospf_wan1
      set cost 10
      set interface tunnel_wan1
      set network-type point-to-point
    end
  config redistribute connected
    set status enable
  end
  config redistribute static
    set status enable
  end
end
end

```

FortiGate_2 OSPF configuration

When configuring FortiGate_2 for OSPF, the loopback interface is created, and then you configure OSPF area networks and interfaces.

Configuring FortiGate_2 differs from FortiGate_1 in that three interfaces are defined instead of two. The third interface is the local LAN that will be advertised into OSPF.

With the exception of creating the loopback interface, OSPF for this example can all be configured in either the web-based manager or CLI.

Creating the loopback interface

A loopback interface can be configured in the CLI only. For example, if the interface will have an IP address of 10.0.0.2, you would enter:

```

config system interface
  edit lback1
    set vdom root
    set ip 10.0.0.2 255.255.255.255
    set type loopback
  end

```

The loopback addresses on the two FortiGate units must be different. For example, set the FortiGate 1 loopback to 10.0.0.1 and the FortiGate 2 loopback to 10.0.0.2.

Configuring OSPF area and interfaces - web-based manager

1. On FortiGate_2, go to **Network > OSPF**.
2. Complete the following.

Router ID	10.0.0.2
Areas	Select Create New , enter the Area and Type and then select OK .
Area	0.0.0.0
Type	Regular
Interfaces	
Name	Enter a name for the OSPF interface, ospf_wan1 for example.
Interface	Select the virtual IPsec interface, tunnel_wan1.
IP	0.0.0.0

- For **Networks**, select **Create New**.
- Enter the following information for the loopback interface:

IP/Netmask	10.0.0.2/255.255.255.255
Area	0.0.0.0

- For **Networks**, select **Create New**.
- Enter the following information for the tunnel interface:

IP/Netmask	10.1.1.0/255.255.255.255
Area	0.0.0.0

- For **Networks**, select **Create New**.
- Enter the following information for the local LAN interface:

IP/Netmask	10.31.101.0/255.255.255.255
Area	0.0.0.0

- Select **Apply**.

Configuring OSPF area and interfaces - CLI

If for example, your loopback interface is 10.0.0.2, your tunnel ends are on the 10.1.1.0/24 network, your local LAN is 10.31.101.0/24, and your virtual IPsec interface is named tunnel_wan1, you would enter:

```
config router ospf
  set router-id 10.0.0.2
  config area
    edit 0.0.0.0
  end
  config network
    edit 1
      set prefix 10.1.1.0 255.255.255.0
    next
```

```
edit 2
    set prefix 10.31.101.0 255.255.255.0
next
edit 2
    set prefix 10.0.0.2 255.255.255.255
end
config ospf-interface
    edit ospf_wan1
        set interface tunnel_wan1
        set network-type point-to-point
    end
end
```

Creating a redundant configuration

You can improve the reliability of the OSPF over IPsec configuration described in the previous section by adding a second IPsec tunnel to use if the default one goes down. Redundancy in this case is not controlled by the IPsec VPN configuration but by the OSPF routing protocol.

To do this you:

- Create a second route-based IPsec tunnel on a different interface and define tunnel end addresses for it.
- Add the tunnel network as part of the OSPF network and define the virtual IPsec interface as an additional OSPF interface.
- Set the OSPF cost for the added OSPF interface to be significantly higher than the cost of the default route.

Adding the second IPsec tunnel

The configuration is the same as in [Configuring the IPsec VPN on page 1804](#), but the interface and addresses will be different. Ideally, the network interface you use is connected to a different Internet service provider for added redundancy.

When adding the second tunnel to the OSPF network, choose another unused subnet for the tunnel ends, 10.1.2.1 and 10.1.2.2 for example.

Adding the OSPF interface

OSPF uses the metric called cost when determining the best route, with lower costs being preferred. Up to now in this example, only the default cost of 10 has been used. Cost can be set only in the CLI.

The new IPsec tunnel will have its OSPF cost set higher than that of the default tunnel to ensure that it is only used if the first tunnel goes down. The new tunnel could be set to a cost of 200 compared to the default cost is 10. Such a large difference in cost will ensure this new tunnel will only be used as a last resort.

If the new tunnel is called tunnel_wan2, you would enter the following on both FortiGate units:

```
config router ospf
    config ospf-interface
        edit ospf_wan2
            set cost 200
            set interface tunnel_wan2
            set network-type point-to-point
        end
    end
```

Redundant OSPF routing over IPsec

This example sets up redundant secure communication between two remote networks using an Open Shortest Path First (OSPF) VPN connection. In this example, the HQ FortiGate unit will be called FortiGate 1 and the Branch FortiGate unit will be called FortiGate 2.

The steps include:

1. Creating redundant IPsec tunnels on FortiGate 1.
2. Configuring IP addresses and OSPF on FortiGate 1.
3. Configuring firewall addresses on FortiGate 1.
4. Configuring security policies on FortiGate 1.
5. Creating redundant IPsec tunnels for FortiGate 2.
6. Configuring IP addresses and OSPF on FortiGate 2.
7. Configuring firewall addresses on FortiGate 2.
8. Configuring security policies on FortiGate 2.

Creating redundant IPsec tunnels on FortiGate 1

1. Go to **VPN > IPsec Tunnels**.
2. Select **Create New**, name the primary tunnel and select **Custom VPN Tunnel (No Template)**.
3. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 2's wan1 IP
Local Interface	wan1 (the primary Internet-facing interface)
Pre-shared Key	Enter

4. Go to **VPN > IPsec Tunnels**.
5. Select **Create New**, name the secondary tunnel and select **Custom VPN Tunnel (No Template)**.
6. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 2's wan2 IP
Local Interface	wan2 (the secondary Internet-facing interface)
Pre-shared Key	Enter

Configuring IP addresses and OSPF on FortiGate 1

1. Go to **Network > Interfaces**.
2. Select the arrow for **wan1** to expand the list.

3. Edit the primary tunnel interface and create IP addresses.

IP	10.1.1.1
Remote IP	10.1.1.2

4. Select the arrow for **wan2** to expand the list.
5. Edit the secondary tunnel interface and create IP addresses.

IP	10.2.1.1
Remote IP	10.2.1.2

6. Go to **Network > OSPF** and enter the **Router ID** for FortiGate 1.
7. Select **Create New** in the **Area** section.
8. Add the backbone area of **0.0.0.0**.
9. Select **Create New** in the **Networks** section.
10. Create the networks and select **Area 0.0.0.0** for each one.
11. Select **Create New** in the **Interfaces** section.
12. Create primary and secondary tunnel interfaces.
13. Set a **Cost** of **10** for the primary interface and **100** for the secondary interface.

Configuring firewall addresses on FortiGate 1

1. Go to **Policy & Objects > Addresses**.
2. Create/Edit the subnets behind FortiGate 1 and FortiGate 2.
3. Create/Edit the primary and secondary interfaces of FortiGate 2.

Configuring security policies on FortiGate 1

1. Go to **Policy & Objects > IPv4 Policy**.
2. Create the four security policies required for both FortiGate 1's primary and secondary interfaces to connect to FortiGate 2's primary and secondary interfaces.

Creating redundant IPsec tunnels on FortiGate 2

1. Go to **VPN > IPsec Tunnels**.
2. Select **Create New**, name the primary tunnel and select **Custom VPN Tunnel (No Template)**.
3. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 1's wan1 IP
Local Interface	wan1 (the primary Internet-facing interface)
Pre-shared Key	Enter

4. Go to **VPN > IPsec Tunnels**.
5. Select **Create New**, name the secondary tunnel and select **Custom VPN Tunnel (No Template)**.
6. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 1's wan1 IP
Local Interface	wan2 (the secondary Internet-facing interface)
Pre-shared Key	Enter

Configuring IP addresses and OSPF on FortiGate 1

1. Go to **Network > Interfaces**.
2. Select the arrow for **wan1** to expand the list.
3. Edit the primary tunnel interface and create IP addresses.

IP	10.1.1.2
Remote IP	10.1.1.1

4. Select the arrow for **wan2** to expand the list.
5. Edit the secondary tunnel interface and create IP addresses.

IP	10.2.1.2
Remote IP	10.2.1.1

6. Go to **Network > OSPF** and enter the **Router ID** for FortiGate 2.
7. Select **Create New** in the **Area** section.
8. Add the backbone area of **0.0.0.0**.
9. Select **Create New** in the **Networks** section.
10. Create the networks and select **Area 0.0.0.0** for each one.
11. Select **Create New** in the **Interfaces** section.
12. Create primary and secondary tunnel interfaces.
13. Set a **Cost** of **10** for the primary interface and **100** for the secondary interface.

Configuring firewall addresses on FortiGate 2

1. Go to **Policy & Objects > Addresses**.
2. Create/Edit the subnets behind FortiGate 1 and FortiGate 2.
3. Create/Edit the primary and secondary interfaces of FortiGate 2.

Configuring security policies on FortiGate 2

1. Go to **Policy & Objects > IPv4 Policy**.
2. Create the four security policies required for both FortiGate 2's primary and secondary interfaces to connect to FortiGate 1's primary and secondary interfaces.

Results

1. Go to **Monitor > IPsec Monitor** to verify the statuses of both the primary and secondary IPsec VPN tunnels on FortiGate 1 and FortiGate 2.
2. Go to **Monitor > Routing Monitor**. Monitor to verify the routing table on FortiGate 1 and FortiGate 2. Type **OSPF** for the **Type** and select **Apply Filter** to verify the OSPF route.
3. Verify that traffic flows via the primary tunnel:
 - From a PC1 set to IP:10.20.1.100 behind FortiGate 1, run a tracer to a PC2 set to IP address 10.21.1.100 behind FortiGate 2 and vice versa.
 - From PC1, you should see that the traffic goes through 10.1.1.2 which is the primary tunnel interface IP set on FortiGate 2.
 - From PC2, you should see the traffic goes through 10.1.1.1 which is the primary tunnel interface IP set on FortiGate 1.
4. The VPN network between the two OSPF networks uses the primary VPN connection. Disconnect the wan1 interface and confirm that the secondary tunnel will be used automatically to maintain a secure connection.
5. Verify the IPsec VPN tunnel statuses on FortiGate 1 and FortiGate 2. Both FortiGates should show that primary tunnel is DOWN and secondary tunnel is UP.
6. Go to **Monitor > IPsec Monitor** to verify the status.
7. Verify the routing table on FortiGate 1 and FortiGate 2.
The secondary OSPF route (with cost = 100) appears on both FortiGate units.
8. Go to **Monitor > Routing Monitor**. Type **OSPF** for the **Type** and select **Apply Filter** to verify OSPF route.
9. Verify that traffic flows via the secondary tunnel:
 - From a PC1 set to IP:10.20.1.100 behind FortiGate 1, run a tracer to a PC2 set to IP:10.21.1.100 behind FortiGate 2 and vice versa.
 - From PC1, you should see that the traffic goes through 10.2.1.2 which is the secondary tunnel interface IP set on FortiGate 2.
 - From PC2, you should see the traffic goes through 10.2.1.1 which is the secondary tunnel interface IP set on FortiGate 1.

OSPF over dynamic IPsec

The following example shows how to create a dynamic IPsec VPN tunnel that allows OSPF.

Configuring IPsec on FortiGate 1

1. Go to **Dashboard** and enter the **CLI Console** widget
2. Create phase 1:

```
config vpn ipsec phase1-interface
  edit "dial-up"
    set type dynamic
    set interface "wan1"
    set mode-cfg enable
    set proposal 3des-shal
    set add-route disable
    set ipv4-start-ip 10.10.101.0
    set ipv4-end-ip 10.10.101.255
    set psksecret
  next
end
```

3. Create phase 2:

```
config vpn ipsec phase2-interface
  edit "dial-up-p2"
    set phase1name "dial-up"
    set proposal 3des-shal aes128-shal
  next
end
```

Configuring OSPF on FortiGate 1

1. Go to **Dashboard** and enter the **CLI Console** widget.
2. Create OSPF route.

```
config router ospf
  set router-id 172.20.120.22
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.10.101.0 255.255.255.0
    next
  end
  config redistribute "connected"
    set status enable
  end
  config redistribute "static"
    set status enable
  end
end
```

Adding policies on FortiGate 1

1. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing OSPF traffic from **dial-up** to **port5**.
2. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing OSPF traffic from **port5** to **dial-up** interfaces.

Configuring IPsec on FortiGate 2

1. Go to **Dashboard** and enter the **CLI Console** widget
2. Create phase 1:

```
config vpn ipsec phase1-interface
  edit "dial-up-client"
    set interface "wan1"
    set mode-cfg enable
    set proposal 3des-sha1
    set add-route disable
    set remote-gw 172.20.120.22
    set psksecret
  next
end
```

3. Create phase 2:

```
config vpn ipsec phase2-interface
  edit "dial-up-client"
    set phase1name "dial-up-client"
    set proposal 3des-sha1 aes128-sha1
    set auto-negotiate enable
  next
end
```

Configuring OSPF on FortiGate 2

1. Go to **Dashboard** and enter the **CLI Console** widget.
2. Create OSPF route.

```
config router ospf
  set router-id 172.20.120.15
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.10.101.0 255.255.255.0
    next
  end
  config redistribute "connected"
    set status enable
  end
  config redistribute "static"
    set status enable
  end
end
```

Adding policies on FortiGate 2

1. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing OSPF traffic from **dial-up-client** to **port5**.
2. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing OSPF traffic from **port5** to **dial-up-client** interfaces.

Verifying the tunnel is up

Go to **Monitor > IPsec Monitor** to verify that the tunnel is **Up**.

Results

1. From FortiGate 1, go to **Monitor > Routing Monitor** and verify that routes from FortiGate 2 were successfully advertised to FortiGate 1 via OSPF.
2. From FortiGate 1, go to **Dashboard**. Enter the CLI Console widget and type this command to verify OSPF neighbors:

```
get router info ospf neighbor
```

```
OSPF process 0:
Neighbor      ID Pri State Dead   Time      Address Interface
172.20.120.25 1  Full /      -    00:00:34 10.10.101.1 dial-up_0
```

3. From FortiGate 2, go to **Monitor > Routing Monitor** and verify that routes from FortiGate 1 were successfully advertised to FortiGate 2 via OSPF.
4. From FortiGate 2, go to **Dashboard**. Enter the CLI Console widget and type this command to verify OSPF neighbors:

```
get router info ospf neighbor
```

```
OSPF process 0:
Neighbor      ID Pri State Dead   Time      Address Interface
172.20.120.22 1  Full /      -    00:00:30 10.10.101.2 dial-up_client
```

BGP over dynamic IPsec

The following example shows how to create a dynamic IPsec VPN tunnel that allows BGP.

Configuring IPsec on FortiGate 1

1. Go to **Policy & Objects > Addresses** and select create new **Address**.

Name	Remote_loop_int
Type	Subnet
Subnet/IP Range	10.10.10.10
Interface	any

2. Create an **Address Group**.

Group Name	VPN_DST
Show in Address List	enable
Members	Remote_loop_int all

3. Go to **Dashboard** and enter the CLI Console widget.
4. Create phase 1:

```
config vpn ipsec phase1-interface
edit Dialup
    set type dynamic
    set interface wan1
    set mode aggressive
    set peertype one
    set mode-cfg enable
    set proposal 3des-sha1 aes128-sha1
    set peerid dial
    set assign-ip disable
    set psksecret
next
end
```

5. Create phase 2:

```
config vpn ipsec phase2-interface
edit dial_p2
    set phase1name Dialup
    set proposal 3des-sha1 aes128-sha1
    set src-addr-type name
    set dst-addr-type name
    set src-name all
    set dst-name VPN_DST
```

```

    next
end

```

Configuring BGP on FortiGate 1

1. Go to **Network > Interfaces** and create a Loopback interface.
2. Set **IP/Network Mask** to **20.20.20.20/255.255.255.255**.
3. Go to **Dashboard** and enter the CLI Console widget.
4. Create a BGP route.

```

config router bgp
    set as 100
    set router-id 1.1.1.1
    config neighbor
        edit 10.10.10.10
            set ebgp-enforce-multihop enable
            set remote-as 200
            set update-source loop
        next
    end
    config redistribute connected
        set status enable
    end
end

```

Adding policies on FortiGate 1

1. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing BGP traffic from **Dialup** to **loop** interfaces.
2. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing BGP traffic from **loop** to **Dialup** interfaces.

Configuring IPsec on FortiGate 2

1. Go to **Dashboard** and enter the CLI Console widget.
2. Create phase 1:

```

config vpn ipsec phase1-interface
    edit Dialup
        set interface wan1
        set mode aggressive
        set mode-cfg enable
        set proposal 3des-sha1 aes128-sha1
        set localid dial
        set remote-gw 172.20.120.22
        set assign-ip disable
        set psksecret
    next
end

```

3. Create phase 2:

```

config vpn ipsec phase2-interface
    edit dial_p2
        set phase1name Dialup
        set proposal 3des-sha1 aes128-sha1
        set keepalive enable
    next
end

```

Configuring BGP on FortiGate 2

1. Go to **Network > Interfaces** and create a Loopback interface.
2. Set **IP/Network Mask** to **10.10.10.10/255.255.255.255**.
3. Go to **Dashboard** and enter the **CLI Console** widget.
4. Create a BGP route.

```
config router bgp
  set as 200
  set router-id 1.1.1.2
  config neighbor
    edit 20.20.20.20
      set ebgp-enforce-multihop enable
      set remote-as 100
      set update-source loop
    next
  end
  config redistribute connected
    set status enable
  end
end
```

Adding policies on FortiGate 2

1. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing BGP traffic from **Dialup** to **loop** interfaces.
2. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing BGP traffic from **loop** to **Dialup** interfaces.

Adding a static route on FortiGate 2

Go to **Network > Static Routes** and add a route to the remote Loopback interface via Dialup interface.

Destination IP/Mask	20.20.20.20/255.255.255.255
Device	Dialup
Administrative Distance	10

Verifying the tunnel is up

Go to **Monitor > IPsec Monitor** to verify that the tunnel is **Up**.

Results

1. From FortiGate 1, go to **Monitor > Routing Monitor** and verify that routes from FortiGate 2 were successfully advertised to FortiGate 1 via BGP.
2. From FortiGate 1, go to **Dashboard**.
3. Enter the **CLI Console** widget and type this command to verify BGP neighbors:

```
get router info bgp summary
```
4. From FortiGate 2, go to **Monitor > Routing Monitor** and verify that routes from FortiGate 1 were successfully advertised to FortiGate 2 via BGP.

5. From FortiGate 2, go to **Dashboard**.
6. Enter the **CLI Console** widget and type this command to verify BGP neighbors:

```
get router info bgp summary
```

IPsec Auto-Discovery VPN (ADVPN)

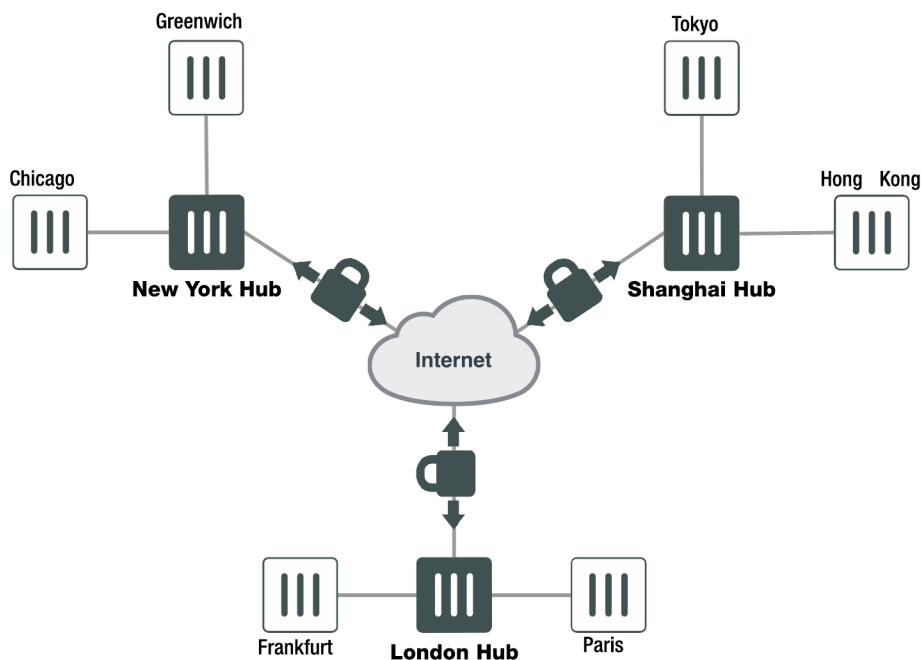

Consider a company that wants to provide direct secure (IPsec) connections between all of its offices in New York, Chicago, Greenwich, London, Paris, Frankfurt, Tokyo, Shanghai, and Hong Kong.

A straightforward solution is to create a full mesh of connections such that every site has eight IPsec configurations, one for each of the other sites. If there were ninety sites, that could still be done but now the configuration is becoming tedious, since every time a new site is added, N-1 other sites have to have their configuration updated.

An efficient and secure alternative is IPsec Auto-Discovery VPN (ADVPN), which allows a minimum amount of configuration per site but still allows direct IPsec connections to be made between every site. [RFC 7018](#) essentially describes this problem, along with some requirements for candidate solutions.

The ADVPN solution involves partitioning the sites into spokes and hubs such that a spoke has to have enough IPsec configuration to enable it to connect to at least one hub. A hub does not have specific configuration for each spoke, so the amount of configuration does not grow with the number of spokes that are connected to that hub. A hub to hub connection would typically involve both hubs having configuration for each other.

So, one possible partition for the original nine sites would be that Chicago and Greenwich would be spokes for the New York hub, Paris and Frankfurt would be spokes for the London hub, and Tokyo and Hong Kong would be spokes for the Shanghai hub:

Once a spoke has established a connection to its hub then initially IPsec traffic to another site transits via one or more hubs. For example, traffic from Chicago to Hong Kong would transit via the New York and Shanghai hubs. This transit traffic then triggers an attempt to create a more direct connection.

In FortiOS:

- Direct connections are only created between the two endpoints that want to exchange traffic (e.g. Chicago and Hong Kong); we do not create intermediate connections (say Chicago to Shanghai, or New York to Hong Kong) as a side-effect.
- Learning the peer subnets is done via a dynamic routing protocol running over the IPsec connections.
- Negotiation of the direct connections is done via IKE.
- Both PSK and certificate authentication is supported.

Example ADVPN configuration

Since dynamic routing with IPsec under FortiOS requires that an interface have an IP address, then for every site a unique IP address from some unused range is allocated. For example we'll assume that 10.100.0.0/16 is unused and so assign the IP addresses:

- | | | |
|------------------------|-----------------------|------------------------|
| • Chicago 10.100.0.4 | • London 10.100.0.2 | • Frankfurt 10.100.0.7 |
| • Greenwich 10.100.0.5 | • Shanghai 10.100.0.3 | • Hong Kong 10.100.0.8 |
| • New York 10.100.0.1 | • Paris 10.100.0.6 | • Tokyo 10.100.0.9 |

We'll assume that each site has one or more subnets that it protects that it wants to make available to the peers. For the purposes of exposition we'll assume there is only one subnet per site and they are allocated as:

- | | | |
|-------------------------|------------------------|-------------------------|
| • Chicago 10.0.4.0/16 | • London 10.0.2.0/24 | • Frankfurt 10.0.7.0/24 |
| • Greenwich 10.0.5.0/24 | • Shanghai 10.0.3.0/24 | • Hong Kong 10.0.8.0/24 |
| • New York 10.0.1.0/24 | • Paris 10.0.6.0/24 | • Tokyo 10.0.9.0/24 |

Our example network topology now looks like this:

The configuration in Chicago would be as follows:

```
config vpn ipsec phase1-interface
  edit "New York"
    set type static
    set interface wan1
    set remote-gw <New-York-IP-address>
    set psk <New-York-PSK>
    set auto-discovery-receiver enable
  next
end
```

The attribute `auto-discovery-receiver` indicates that this IPsec tunnel wishes to participate in an auto-discovery VPN. The IPsec interface would then have its IP assigned according to the Chicago address:

```
config system interface
  edit "New York"
    set ip 10.100.0.4/32
    set remote-ip 10.100.0.1
  next
end
```

RIP (for simplicity, you could use OSPF or BGP) is then configured to run on the IPsec interface and on the Chicago subnet (you could use `redistribute connected`, but we'll allow for the fact that there may be other subnets learned from another router on the 10.0.4.0/24 subnet):

```
config router rip
```

```
edit 1
    set prefix 10.100.0.0/16
next
edit 2
    set prefix 10.0.4.0/24
next
end
```

Other than the firewall policy and a minimal phase 2 configuration, this concludes the configuration for Chicago.

Each spoke would have a similar configuration.

The New York hub would have a dynamic phase 1 for its spoke connections, and two static phase 1s for its connections to the other hubs:

```
config vpn ipsec phase1-interface
edit "Spokes"
    set type dynamic
    set interface wan1
    set psk <New-York-PSK>
    set auto-discovery-sender enable
    set auto-discovery-psk enable
    set add-route disable
next
edit "London"
    set type static
    set interface wan1
    set psk <New-York-London-PSK>
    set auto-discovery-forwarder enable
next
edit "Shanghai"
    set type static
    set interface wan1
    set psk <New-York-Shanghai-PSK>
    set auto-discovery-forwarder enable
next
end
```

The 'Spokes' connection has `set auto-discovery-sender enable` to indicate that when IPsec traffic transits the hub it should optionally generate a message to the initiator of the traffic to indicate that it could perhaps establish a more direct connection. The `set add-route disable` ensures that IKE does not automatically add a route back over the spoke and instead leaves routing to a separately configured routing protocol.

The two inter-hub connections have `set auto-discovery-forwarder enable` to indicate that these connections can participate in the auto-discovery process. The interface IP addresses are assigned:

```
config system interface
edit "Spokes"
    set ip 10.100.0.1/32
    set remote-ip 10.100.0.254
next
edit "London"
    set ip 10.100.0.1/32
    set remote-ip 10.100.0.2
next
edit "Shanghai"
    set ip 10.100.0.1/32
```

```
        set remote-ip 10.100.0.3
    next
end
```

Following this, RIP is enabled on the relevant interfaces:

```
config router rip
    edit 1
        set prefix 10.100.0.0/16
    next
    edit 2
        set prefix 10.0.1.0/24
    next
end
```

A similar configuration would be used on the other two hubs.

Traffic flow and tunnel connection

With the configuration in place at all spokes and hubs, assuming all the spokes are connected to a hub, then Chicago would learn (via RIP) that the route to the Hong Kong subnet 10.0.8.0/24 is via its "New York" interface. If a device on the Chicago protected subnet (say 10.0.4.45) attempted to send traffic to the Hong Kong protected subnet (say 10.0.8.13) then it should flow over the New York interface to New York, which should then transmit it over the Shanghai tunnel to Shanghai, which should then send it over the dynamically negotiated Hong Kong tunnel to Hong Kong.

At the point when the traffic transits New York it should notice that the Chicago Spoke tunnel and the Shanghai tunnel have auto-discovery enabled, causing the New York hub to send a message via IKE to Chicago informing it that it may want to try and negotiate a direct connection for traffic from 10.0.4.45 to 10.0.8.13.

On receipt of this message, IKE on Chicago creates the (FortiOS-specific) IKE INFORMATIONAL SHORTCUT-QUERY message which contains the Chicago public IP address, the source IP of the traffic (10.0.4.45), the desired destination IP (10.0.8.13), and the PSK that should be used to secure any direct tunnel (if certificates are configured, it is assumed that they all share the same CA and so no additional authentication information is required). This message is sent via IKE to New York since routing indicates that New York is the best route to 10.0.8.13.

On receipt of the IKE INFORMATIONAL query, New York checks its routing table to see who owns 10.0.8.13. It finds that 10.0.8.13 should be routed via Shanghai, and since Shanghai is marked as an auto-discovery-forwarder then the query is forwarded.

Shanghai repeats the process, finds that 10.0.8.13 should be routed via its Hong Kong Spoke and so sends it to Hong Kong. Hong Kong checks 10.0.8.13, finds that it owns the subnet, so it remembers the Chicago public IP address (and PSK) and creates an IKE INFORMATIONAL reply message containing its external IP address. To work out where to send the IKE message, the FortiGate does a routing lookup for the original source IP (10.0.4.45), determines that the message should be routed via its Shanghai tunnel and so sends the reply back to Shanghai. The reply then makes its way back to Chicago following the reverse of the path that it used to arrive at Hong Kong.

When the reply makes it back to the Chicago initiator then it now knows the IP address of the Hong Kong device. Chicago now creates a new dynamic tunnel with the remote gateway as the Hong Kong public IP address and initiates an IKE negotiation (the dynamic tunnel name is auto-generated from the tunnel over which it performed the query; in this case it would be called 'New York_0').

This negotiation should succeed since Hong Kong is set up to expect an attempted negotiation from the Chicago public IP address. Once the negotiation succeeds, RIP will start to run on the newly created tunnels at Chicago and Hong Kong. This will update the routing on Chicago (and Hong Kong) so that the preferred route to 10.0.8.0 (10.0.4.0) is via the newly created tunnel rather than via the connection to New York (Shanghai).

Notes about ADVPN in FortiOS

- Auto-discovery is only supported by IKEv1.
- All Spokes must have an IP address that is routable from any other spoke; devices behind NAT are not currently supported.
- The feature requires the use of a dynamic routing protocol. There is no support for IKE handling routing.
- RIP is not a very scalable routing protocol. When there are more than a few spokes it would be advisable to use route summarization to avoid huge RIP updates. Better yet, use BGP instead of RIP.
- It is assumed that spokes will not be used to transit other spoke traffic, for example: traffic from Chicago to Tokyo would not transit an existing Chicago to Hong Kong tunnel even though that has a shorter hop count than a route via New York and Shanghai.
- There is no facility to allow you to filter which traffic that transits the hub should trigger the message sent to the initiator suggesting it create a direct connection. Currently any and all traffic will trigger it.

Logging and monitoring

This section provides some general logging and monitoring procedures for VPNs.

The following topics are included in this section:

Monitoring VPN connections

You can use the monitor to view activity on IPsec VPN tunnels and to start or stop those tunnels. The display provides a list of addresses, proxy IDs, and timeout information for all active tunnels.

Monitoring connections to remote peers

The list of tunnels provides information about VPN connections to remote peers that have static IP addresses or domain names. You can use this list to view status and IP addressing information for each tunnel configuration. You can also start and stop individual tunnels from the list.

To view the list of static-IP and dynamic-DNS tunnels go to **Monitor > IPsec Monitor**.

Monitoring dialup IPsec connections

The list of dialup tunnels provides information about the status of tunnels that have been established for dialup clients. The list displays the IP addresses of dialup clients and the names of all active tunnels. The number of tunnels shown in the list can change as dialup clients connect and disconnect.

To view the list of dialup tunnels go to **Monitor > IPsec Monitor**.

If you take down an active tunnel while a dialup client such as FortiClient is still connected, FortiClient will continue to show the tunnel connected and idle. The dialup client must disconnect before another tunnel can be initiated.

The list of dialup tunnels displays the following statistics:

- The Name column displays the name of the tunnel.
- The meaning of the value in the Remote gateway column changes, depending on the configuration of the network at the far end:
 - When a FortiClient dialup client establishes a tunnel, the Remote gateway column displays either the public IP address and UDP port of the remote host device (on which the FortiClient Endpoint Security application is installed), or if a NAT device exists in front of the remote host, the Remote gateway column displays the public IP address and UDP port of the remote host.
 - When a FortiGate dialup client establishes a tunnel, the Remote gateway column displays the public IP address and UDP port of the FortiGate dialup client.
- The Username column displays the peer ID, certificate name, or XAuth user name of the dialup client (if a peer ID, certificate name, or XAuth user name was assigned to the dialup client for authentication purposes).
- The Timeout column displays the time before the next key exchange. The time is calculated by subtracting the time elapsed since the last key exchange from the keylife.
- The Proxy ID Source column displays the IP addresses of the hosts, servers, or private networks behind the FortiGate unit. A network range may be displayed if the source address in the security encryption policy was expressed as a range of IP addresses.

- The meaning of the value in the Proxy ID Destination column changes, depending on the configuration of the network at the far end:
 - When a FortiClient dialup client establishes a tunnel:
 - If VIP addresses are not used and the remote host connects to the Internet directly, the Proxy ID Destination field displays the public IP address of the Network Interface Card (NIC) in the remote host.
 - If VIP addresses are not used and the remote host is behind a NAT device, the Proxy ID Destination field displays the private IP address of the NIC in the remote host.
 - If VIP addresses were configured (manually or through FortiGate DHCP relay), the Proxy ID Destination field displays either the VIP address belonging to a FortiClient dialup client, or a subnet address from which VIP addresses were assigned.
- When a FortiGate dialup client establishes a tunnel, the Proxy ID Destination field displays the IP address of the remote private network.

VPN event logs

You can configure the FortiGate unit to log VPN events. For IPsec VPNs, Phase 1 and Phase 2 authentication and encryption events are logged. For information about how to interpret log messages, see the [FortiGate Log Message Reference](#).

Logging VPN events

1. Go to **Log & Report > Log Settings**.
2. Verify that the **VPN activity event** option is selected.
3. Select **Apply**.

Viewing event logs

1. Go to **Log & Report > VPN Events**.
2. Select the **Log location**.

Sending tunnel statistics to FortiAnalyzer

By default, logged events include tunnel-up and tunnel-down status events. Other events, by default, will appear in the FortiAnalyzer report as "No Data Available". More accurate results require logs with `action=tunnel-stats`, which is used in generating reports on the FortiAnalyzer (rather than the tunnel-up and tunnel-down event logs). The FortiGate does not, by default, send `tunnel-stats` information.

To allow VPN `tunnel-stats` to be sent to FortiAnalyzer, configure the FortiGate unit as follows using the CLI:

```
config system settings
    set vpn-stats-log ipsec ssl
    set vpn-stats-period 300
end
```

Troubleshooting

This section contains tips to help you with some common challenges of IPsec VPNs.

A VPN connection has multiple stages that can be confirmed to ensure the connection is working properly. It is easiest to see if the final stage is successful first since if it is successful the other stages will be working properly. Otherwise, you will need to work back through the stages to see where the problem is located.

When a VPN connection is properly established, traffic will flow from one end to the other as if both ends were physically in the same place. If you can determine the connection is working properly then any problems are likely problems with your applications.

On some FortiGate units, such as the FortiGate 94D, you cannot ping over the IPsec tunnel without first setting a source-IP. In this scenario, you must assign an IP address to the virtual IPsec VPN interface. Anything sourced from the FortiGate going over the VPN will use this IP address.

If the egress/outgoing interface (determined by kernel route) has an IP address, then use the IP address of the egress/outgoing interface. Otherwise, use the IP address of the first interface from the interface list (that has an IP address).

The first diagnostic command worth running, in any IPsec VPN troubleshooting situation, is the following:

```
diagnose vpn tunnel list
```

This command is very useful for gathering statistical data such as the number of packets encrypted versus decrypted, the number of bytes sent versus received, the SPI identifier, etc. This kind of information in the resulting output can make all the difference in determining the issue with the VPN.

Another appropriate diagnostic command worth trying is:

```
diagnose debug flow
```

This command will inform you of any lack of firewall policy, lack of forwarding route, and of policy ordering issues.

Common IPsec VPN problems

The most common IPsec VPN issues are listed below. Please read thoroughly and note that, although the list is extensive, it is not exhaustive.

This section includes support for the following:

- [Failed VPN connection attempts](#)
- [Debug output table](#)
- [The options to configure policy-based IPsec VPN are unavailable](#)
- [The VPN tunnel goes down frequently](#)
- [The pre-shared key does not match \(PSK mismatch error\)](#)
- [The SA proposals do not match \(SA proposal mismatch\)](#)
- [Pre-existing IPsec VPN tunnels need to be cleared](#)
- [Other potential VPN issues](#)

Failed VPN connection attempts

If your VPN fails to connect, check the following:

- Ensure that the **pre-shared keys** match exactly (see [The pre-shared key does not match \(PSK mismatch error\)](#) below).
- Ensure that both ends use the same P1 and P2 proposal settings (see [The SA proposals do not match \(SA proposal mismatch\)](#) below).
- Ensure that you have allowed inbound and outbound traffic for all necessary network services, especially if services such as DNS or DHCP are having problems.
- Check that a static route has been configured properly to allow routing of VPN traffic.

If you are still unable to connect to the VPN tunnel, run the following diagnostic command in the CLI:

```
diagnose debug application ike -1
diagnose debug enable
```

The resulting output may indicate where the problem is occurring. When you are finished, disable the diagnostics by using the following command:

```
diagnose debug reset
diagnose debug disable
```

View the table below for some assistance in analyzing the debug output.

Debug output table

Problem	Debug output	Common causes	Common solutions
Tunnel is not coming up	Error: negotiation failure	IPsec configuration mismatch	Check phase 1 and 2 settings
	Error: no SA proposal chosen	IPsec configuration mismatch	Check phase 1 and 2 settings
	FortiGate using the wrong VPN	Missing or wrong local ID	If there are more than one pre-shared key dial-up VPN with the same local gateway, use aggressive mode and different local IDs
	Error: connection expiring due to XAUTH failure	Wrong username, password, or user group	Check user credentials and user group configuration
	Error: peer has not completed XAUTH exchange	XAuth is disabled in the client	Fix the client's XAuth configuration
Tunnel is bouncing	DPD packets lost	ISP issue	Check the ISP connection

Problem	Debug output	Common causes	Common solutions
Tunnel is up but traffic does not go through	Error: No matching IPsec selector, drop	Quick mode selector mismatch	Fix the quick mode selector
		NAT is enabled	Disable NAT in the firewall policy
	Traffic is not routed to the tunnel	Route or firewall policy misconfiguration	Route-based: traffic must be routed to IPsec virtual interface Policy-based: traffic must match a firewall policy with action set to IPSEC

The options to configure policy-based IPsec VPN are unavailable

Go to **System > Feature Visibility**. Select **Show More** and turn on **Policy-based IPsec VPN**.

The VPN tunnel goes down frequently

If your VPN tunnel goes down often, check the Phase 2 settings and either increase the **Keylife** value or enable **Autokey Keep Alive**.

The pre-shared key does not match (PSK mismatch error)

It is possible to identify a PSK mismatch using the following combination of CLI commands:

```
diag vpn ike log filter name <phase1-name>
diag debug app ike -1
diag debug enable
```

This will provide you with clues as to any PSK or other proposal issues. If it is a PSK mismatch, you should see something similar to the following output:

```
ike 0:TRX:322: PSK auth failed: probable pre-shared key mismatch
ike Negotiate SA Error:
```

The SA proposals do not match (SA proposal mismatch)

The most common problem with IPsec VPN tunnels is a mismatch between the proposals offered between each party. Without a match and proposal agreement, Phase 1 can never establish. Use the following command to show the proposals presented by both parties.

```
diag debug app ike -1
diag debug enable
```

The resulting output should include something similar to the following, where **blue** represents the remote VPN device, and **green** represents the local FortiGate.

```
responder received SA_INIT msg
incoming proposal:
proposal id = 1:
  protocol = IKEv2:
    encapsulation = IKEv2/none
    type=ENCR, val=AES_CBC (key_len = 256)
    type=INTEGR, val=AUTH_HMAC_SHA_96
    type=PRF, val=PRF_HMAC_SHA
    type=DH_GROUP, val=1536.
```

```
proposal id = 2:
  protocol = IKEv2:
    encapsulation = IKEv2/none
    type=ENCR, val=3DES_CBC
    type=INTEGR, val=AUTH_HMAC_SHA_2_256_128
    type=PRF, val=PRF_HMAC_SHA2_256
    type=DH_GROUP, val=1536.
proposal id = 1:
  protocol = IKEv2:
    encapsulation = IKEv2/none
    type=ENCR, val=AES_CBC (key_len = 128)
    type=INTEGR, val=AUTH_HMAC_SHA_96
    type=PRF, val=PRF_HMAC_SHA
    type=DH_GROUP, val=1536.
```

Pre-existing IPsec VPN tunnels need to be cleared

Should you need to clear an IKE gateway, use the following commands:

```
diagnose vpn ike restart
diagnose vpn ike gateway clear
```

Other potential VPN issues

- Ensure that your FortiGate unit is in NAT/Route mode, rather than Transparent.
- Check your NAT settings, enabling NAT traversal in the Phase 1 configuration while disabling NAT in the security policy. You might need to pin the PAT/NAT session table, or use some of kind of NAT-T keepalive to avoid the expiration of your PAT/NAT translation.
- Ensure that both ends of the VPN tunnel are using Main mode, unless multiple dial-up tunnels are being used.
- Remove any Phase 1 or Phase 2 configurations that are not in use. If a duplicate instance of the VPN tunnel appears on the IPsec Monitor, reboot your FortiGate unit to try and clear the entry.
- If you have multiple dial-up IPsec VPNs, ensure that the peer ID is configured properly on the FortiGate and that clients have specified the correct local ID. Furthermore, in circumstances where multiple remote dialup VPN tunnels exist, each tunnel must have a peer ID set.
- If you are using FortiClient, ensure that your version is compatible with the FortiGate firmware by reading the FortiOS Release Notes.
- If you are using Perfect Forward Secrecy (PFS), ensure that it is used on both peers. You can use the `diagnose vpn tunnel list` command to troubleshoot this.
- Ensure that the **Quick Mode selectors** are correctly configured. If part of the setup currently uses firewall addresses or address groups, try changing it to either specify the IP addresses or use an expanded address range. This is especially useful if the remote endpoint is not a FortiGate device.
- If XAUTH is enabled, ensure that the settings are the same for both ends, and that the FortiGate unit is set to **Enable as Server**.
- Check IPsec VPN Maximum Transmission Unit (MTU) size. A 1500 byte MTU is going to exceed the overhead of the ESP-header, including the additional ip_header, etc. You can use the `diagnose vpn tunnel list` command to troubleshoot this.
- If your FortiGate unit is behind a NAT device, such as a router, configure port forwarding for UDP ports 500 and 4500.

Troubleshooting connection issues

The following section includes troubleshooting suggestions related to:

- [LAN interface connection](#)
- [Dialup connection](#)
- [Troubleshooting VPN connections](#)
- [Troubleshooting invalid ESP packets using Wireshark](#)
- [Attempting hardware offloading beyond SHA1](#)
- [Check Phase 1 proposal settings](#)
- [Check your routing](#)
- [Try enabling XAuth](#)

LAN interface connection

To confirm whether a VPN connection over LAN interfaces has been configured correctly, issue a ping or traceroute command on the network behind the FortiGate unit to test the connection to a computer on the remote network. If the connection is properly configured, a VPN tunnel will be established automatically when the first data packet destined for the remote network is intercepted by the FortiGate unit.

If the ping or traceroute fail, it indicates a connection problem between the two ends of the tunnel. This may or may not indicate problems with the VPN tunnel. You can confirm this by going to **Monitor > IPsec Monitor** where you will be able to see your connection. A green arrow means the tunnel is up and currently processing traffic. A red arrow means the tunnel is not processing traffic, and this VPN connection has a problem.

If the connection has problems, see [Troubleshooting VPN connections on page 1833](#).

Dialup connection

A dialup VPN connection has additional steps. To confirm that a VPN between a local network and a dialup client has been configured correctly, at the dialup client, issue a ping command to test the connection to the local network. The VPN tunnel initializes when the dialup client attempts to connect.

If the ping or traceroute fail, it indicates a connection problem between the two ends of the tunnel. This may or may not indicate problems with the VPN tunnel, or dialup client. As with the LAN connection, confirm the VPN tunnel is established by checking **Monitor > IPsec Monitor**.

Troubleshooting VPN connections

If you have determined that your VPN connection is not working properly through [Troubleshooting on page 1829](#), the next step is to verify that you have a phase2 connection.

If traffic is not passing through the FortiGate unit as you expect, ensure the traffic does not contain IPcomp packets (IP protocol 108, RFC 3173). FortiGate units do not allow IPcomp packets, they compress packet payload, preventing it from being scanned.

Testing Phase 1 and 2 connections is a bit more difficult than testing the working VPN. This is because they require diagnose CLI commands. These commands are typically used by Fortinet customer support to discover more information about your FortiGate unit and its current configuration.

Before you begin troubleshooting, you must:

- Configure FortiGate units on both ends for interface VPN
- Record the information in your VPN Phase 1 and Phase 2 configurations - for our example here the remote IP address is 10.11.101.10 and the names of the phases are Phase 1 and Phase 2
- Install a telnet or SSH client such as putty that allows logging of output
- Ensure that the admin interface supports your chosen connection protocol so you can connect to your FortiGate unit admin interface.

For this example, default values were used unless stated otherwise.

Obtaining diagnose information for the VPN connection - CLI

1. Log into the CLI as admin with the output being logged to a file.
2. Stop any diagnose debug sessions that are currently running with the CLI command
`diagnose debug disable`
3. Clear any existing log-filters by running
`diagnose vpn ike log-filter clear`
4. Set the log-filter to the IP address of the remote computer (10.11.101.10). This filters out all VPN connections except ones to the IP address we are concerned with. The command is
`diagnose vpn ike log-filter dst-addr4 10.11.101.10.`
5. Set up the commands to output the VPN handshaking. The commands are:
`diagnose debug app ike 255`
`diagnose debug enable`

6. Have the remote FortiGate initiate the VPN connection in the web-based manager by going to **VPN > IPsec Tunnels** and selecting **Bring up**.

This makes the remote FortiGate the initiator and the local FortiGate becomes the responder. Establishing the connection in this manner means the local FortiGate will have its configuration information as well as the information the remote computer sends. Having both sets of information locally makes it easier to troubleshoot your VPN connection.

7. Watch the screen for output, and after roughly 15 seconds enter the following CLI command to stop the output.
`diagnose debug disable`
8. If needed, save the log file of this output to a file on your local computer. Saving the output to a file can make it easier to search for a particular phrase, and is useful for comparisons.

Troubleshooting a Phase 1 VPN connection

Using the output from [Obtaining diagnose information for the VPN connection - CLI](#), search for the word `proposal` in the output. It may occur once indicating a successful connection, or it will occur two or more times for an unsuccessful connection — there will be one proposal listed for each end of the tunnel and each possible combination in their settings. For example if 10.11.101.10 selected both Diffie-Hellman Groups 1 and 5, that would be at least 2 proposals set.

A successful negotiation proposal will look similar to

```
IPsec SA connect 26 10.12.101.10->10.11.101.10:500
config found
created connection: 0x2f55860 26 10.12.101.10->10.11.101.10:500
```

```

IPsec SA connect 26 10.12.101.10->10.11.101.10:500 negotiating
no suitable ISAKMP SA, queuing quick-mode request and initiating ISAKMP SA negotiation
initiator: main mode is sending 1st message...
cookie 3db6afe559e3df0f/0000000000000000
out [encryption]
sent IKE msg (ident=ilsend): 10.12.101.10:500->10.11.101.10:500, len=264,
    id=3db6afe559e3df0f/0000000000000000
diaike 0: comes 10.12.101.1:500->10.11.101.1:500,ifindex=26...

```

Note the phrase “initiator: main mode is sending 1st message...” which shows you the handshake between the ends of the tunnel is in progress. Initiator shows the remote unit is sending the first message.

Troubleshooting invalid ESP packets using Wireshark

The following section provides information to help debug an encryption key mismatch. The ESP packet invalid error is due to an encryption key mismatch after a VPN tunnel has been established. When an IPsec VPN tunnel is up, but traffic is not able to pass through the tunnel, Wireshark (or an equivalent program) can be used to determine whether there is an encryption mismatch. A mismatch could occur for many reasons, one of the most common is the instability of an ISP link (ADSL, Cable), or it could effectively be any device in the physical connection.

The following information is required to troubleshoot the problem.

- Take a packet sniffer trace on both FortiGates.
- Run the `diag vpn tunnel list` command a few times on both FortiGates when generating traffic that will pass through the tunnel.

In the following example, the error message was seen on the recipient FortiGate:

```

date=2010-12-28 time=18:19:35 devname=Kosad_VPN device_id=FG300B3910600118 log_
id=0101037132 type=event subtype=ipsec pri=critical vd="root" msg="IPsec ESP" action="error" rem_
ip=180.87.33.2 loc_ip=121.133.8.18 rem_port=32528 loc_port=4500 out_intf="port2"
cookies="88d40f65d555ccaf/05464e20e4afc835" user="N/A" group="N/A" xauth_user="N/A" xauth_
group="N/A" vpn_tunnel="fortinet_0" status=esp_error error_num=Invalid ESP packet detected (HMAC
validation failed). spi=c32b09f7 seq=00000012

```

This is the output of the command `diag vpn tunnel list` on the FortiGate:

```

inet ver=1 serial=2 192.168.1.205:4500->121.133.8.18:4500 lgwy=dyn tun=intf mode=auto bound_if=4

56	64.798749	192.168.1.205	121.133.8.18	ISAKMP	Informational
57	64.957383	121.133.8.18	192.168.1.205	ISAKMP	Informational

How to verify if the original packet has been encrypted correctly

To verify, it is necessary to decrypt the ESP packet using Wireshark. Open the packet capture that is taken from initiator FortiGate using Wireshark. Go to **Edit > Preferences**, expand **Protocol** and look for **ESP**. Select **"Attempt to detect/decode encrypted ESP payloads"**, and fill in the information for the encryption algorithm and the keys. This information can be obtained from the output of the command `diag vpn tunnel list`.

If the packet was encrypted correctly using the correct key, then the decryption will be successful and it will be possible to see the original package as shown below:

13	16.199042	121.133.8.18	192.168.1.205	ISAKMP	Informational
14	16.836503	192.168.1.205	100.100.100.202	ICMP	Echo (ping) request
15	21.192060	192.168.1.205	121.133.8.18	ISAKMP	Informational
16	21.223916	121.133.8.18	192.168.1.205	ISAKMP	Informational
17	21.224790	192.168.1.205	121.133.8.18	ISAKMP	Informational
18	21.392073	121.133.8.18	192.168.1.205	ISAKMP	Informational
19	24.187008	192.168.1.205	100.100.100.202	ICMP	Echo (ping) request
20	26.392870	192.168.1.205	121.133.8.18	ISAKMP	Informational
21	26.746759	121.133.8.18	192.168.1.205	ISAKMP	Informational
22	26.747595	192.168.1.205	121.133.8.18	ISAKMP	Informational
23	26.999062	121.133.8.18	192.168.1.205	ISAKMP	Informational
24	29.687170	192.168.1.205	100.100.100.202	ICMP	Echo (ping) request
25	31.092680	192.168.1.205	121.133.8.18	ISAKMP	Informational
26	32.143504	121.133.8.18	192.168.1.205	ISAKMP	Informational
27	32.143590	192.168.1.205	121.133.8.18	ISAKMP	Informational
28	32.288780	121.133.8.18	192.168.1.205	ISAKMP	Informational
29	35.182775	192.168.1.205	100.100.100.202	ICMP	Echo (ping) request
30	37.282867	192.168.1.205	121.133.8.18	ISAKMP	Informational
31	37.336742	121.133.8.18	192.168.1.205	ISAKMP	Informational

Repeat the decryption process for the packet capture from the recipient firewall. If the decryption failed using the same key, the packet may be corrupted and the interface should then be checked for CRC or packet errors.

Attempting hardware offloading beyond SHA1

If you are trying to off-load VPN processing to a network processing unit (NPU), remember that only SHA1 authentication is supported. For high levels of authentication such as SHA256, SHA384, and SHA512 hardware offloading is not an option—all VPN processing must be done in software—unless using an NP6 (although the NP4lite variation also supports SHA256, SHA384, and SHA512).

Enable/disable IPsec ASIC-offloading

Much like NPU-offload in IKE phase1 configuration, you can enable or disable the usage of ASIC hardware for IPsec Diffie-Hellman key exchange and IPsec ESP traffic. By default hardware offloading is used. For debugging purposes, sometimes it is best for all the traffic to be processed by software.

```
config sys global
    set ipsec-asic-offload [enable | disable]
end
```

Check Phase 1 proposal settings

Ensure that both sides have at least one Phase 1 proposal in common. Otherwise they will not connect. If there are many proposals in the list, this will slow down the negotiating of Phase 1. If its too slow, the connection may timeout before completing. If this happens, try removing some of the unused proposals.

NPU offloading is supported when the local gateway is a loopback interface.

Check your routing

If routing is not properly configured with an entry for the remote end of the VPN tunnel, traffic will not flow properly. You may need static routes on both ends of the tunnel. If routing is the problem, the proposal will likely setup properly but no traffic will flow.

Try enabling XAuth

If one end of an attempted VPN tunnel is using XAuth and the other end is not, the connection attempt will fail. The log messages for the attempted connection will not mention XAuth is the reason, but when connections are failing it is a good idea to ensure both ends have the same XAuth settings. If you do not know the other end's settings enable or disable XAuth on your end to see if that is the problem.

General troubleshooting tips

Most connection failures are due to a configuration mismatch between the FortiGate unit and the remote peer. In general, begin troubleshooting an IPsec VPN connection failure as follows:

1. Ping the remote network or client to verify whether the connection is up. See [General troubleshooting tips on page 1837](#).
2. Traceroute the remote network or client. If DNS is working, you can use domain names. Otherwise use IP addresses.
3. Check the routing behind the dialup client. Routing problems may be affecting DHCP. If this appears to be the case, configure a DHCP relay service to enable DHCP requests to be relayed to a DHCP server on or behind the FortiGate server.
4. Verify the configuration of the FortiGate unit and the remote peer. Check the following IPsec parameters:
 - The mode setting for ID protection (main or aggressive) on both VPN peers must be identical.
 - The authentication method (preshared keys or certificates) used by the client must be supported on the FortiGate unit and configured properly.
 - If preshared keys are being used for authentication purposes, both VPN peers must have identical preshared keys.
 - The remote client must have at least one set of Phase 1 encryption, authentication, and Diffie-Hellman settings that match corresponding settings on the FortiGate unit.
 - Both VPN peers must have the same NAT traversal setting (enabled or disabled).
 - The remote client must have at least one set of Phase 2 encryption and authentication algorithm settings that match the corresponding settings on the FortiGate unit.
 - If you are using manual keys to establish a tunnel, the **Remote SPI** setting on the FortiGate unit must be identical to the **Local SPI** setting on the remote peer, and vice versa.
5. To correct the problem, see the following table.

VPN troubleshooting tips

Configuration problem	Correction
Mode settings do not match.	Select complementary mode settings. See Phase 1 parameters on page 1655 .

Configuration problem	Correction
Peer ID or certificate name of the remote peer or dialup client is not recognized by FortiGate VPN server.	<p>Check Phase 1 configuration. Depending on the Remote Gateway and Authentication Method settings, you have a choice of options to authenticate FortiGate dialup clients or VPN peers by ID or certificate name (see Phase 1 parameters on page 1655).</p> <p>If you are configuring authentication parameters for FortiClient dialup clients, refer to the Authenticating FortiClient Dialup Clients Technical Note.</p>
Preshared keys do not match.	Reenter the preshared key. See Phase 1 parameters on page 1655 .
Phase 1 or Phase 2 key exchange proposals are mismatched.	Make sure that both VPN peers have at least one set of proposals in common for each phase. See Phase 1 parameters on page 1655 and Phase 2 parameters on page 1675 .
NAT traversal settings are mismatched.	Select or clear both options as required. See Phase 1 parameters on page 1655 and Phase 1 parameters on page 1655 .

A word about NAT devices

When a device with NAT capabilities is located between two VPN peers or a VPN peer and a dialup client, that device must be NAT traversal (NAT-T) compatible for encrypted traffic to pass through the NAT device. For more information, see [Phase 1 parameters on page 1655](#).

Troubleshooting L2TP and IPsec

This section describes some checks and tools you can use to resolve issues with L2TP-over-IPsec VPNs.

This section includes:

- [Quick checks](#)
- [Mac OS X and L2TP](#)
- [Setting up logging](#)
- [Using the FortiGate unit debug commands](#)

Quick checks

The table below is a list of common L2TP over IPsec VPN problems and the possible solutions.

Problem	What to check
IPsec tunnel does not come up.	<p>Check the logs to determine whether the failure is in Phase 1 or Phase 2.</p> <p>Check the settings, including encapsulation setting, which must be transport-mode.</p> <p>Check the user password.</p> <p>Confirm that the user is a member of the user group assigned to L2TP.</p> <p>On the Windows PC, check that the IPsec service is running and has not been disabled. See Troubleshooting L2TP and IPsec on page 1838.</p>
Tunnel connects, but there is no communication.	<p>Did you create an ACCEPT security policy from the public network to the protected network for the L2TP clients? See Troubleshooting L2TP and IPsec on page 1838.</p>

Mac OS X and L2TP

FortiOS allows L2TP connections with empty AVP host names and therefore Mac OS X L2TP connections can connect to the FortiGate.

Prior to FortiOS 4.0 MR3, FortiOS refused L2TP connections with empty AVP host names in compliance with [RFC 2661](#) and [RFC 3931](#).

Setting up logging

L2TP logging must be enabled to record L2TP events. Alert email can be configured to report L2TP errors.

Configuring FortiGate logging for L2TP over IPsec

1. Go to **Log & Report > Log Settings**.
2. Select **Event Log**.
3. Select the **VPN activity event** check box.
4. Select **Apply**.

Viewing FortiGate logs

1. Go to **Log & Report > VPN Events**.
2. Select the **Log location** if required.
3. After each attempt to start the L2TP over IPsec VPN, select **Refresh** to view logged events.

Using the FortiGate unit debug commands

Viewing debug output for IKE and L2TP

1. Start an SSH or Telnet session to your FortiGate unit.
2. Enter the following CLI commands

```
diagnose debug application ike -1
diagnose debug application l2tp -1
diagnose debug enable
```

3. Attempt to use the VPN and note the debug output in the SSH or Telnet session.
4. Enter the following command to reset debug settings to default:

```
diagnose debug reset
```

Using the packet sniffer

1. Start an SSH or Telnet session to your FortiGate unit.
2. Enter the following CLI command

```
diagnose sniffer packet any icmp 4
```

3. Attempt to use the VPN and note the debug output.
4. Enter Ctrl-C to end sniffer operation.

Typical L2TP over IPsec session startup log entries - raw format

```

Troubleshooting GRE over IPsec

This section describes some checks and tools you can use to resolve issues with the GRE-over-IPsec VPN.

Quick checks

Here is a list of common problems and what to verify.

Problem	What to check
No communication with remote network.	<p>Use the <code>execute ping</code> command to ping the Cisco device public interface.</p> <p>Use the FortiGate VPN Monitor page to see whether the IPsec tunnel is up or can be brought up.</p>
IPsec tunnel does not come up.	<p>Check the logs to determine whether the failure is in Phase 1 or Phase 2.</p> <p>Check that the encryption and authentication settings match those on the Cisco device.</p> <p>Check the encapsulation setting: tunnel-mode or transport-mode. Both devices must use the same mode.</p>
Tunnel connects, but there is no communication.	<p>Check the security policies. See Troubleshooting GRE over IPsec on page 1841.</p> <p>Check routing. See Troubleshooting GRE over IPsec on page 1841.</p>

Setting up logging

Configuring FortiGate logging for IPsec

1. Go to **Log & Report > Log Settings**.
2. Select the **Event Logging**.

3. Select **VPN activity event**.
4. Select **Apply**.

Viewing FortiGate logs

1. Go to **Log & Report > VPN Events**.
2. Select the log storage type.
3. Select **Refresh** to view any logged events.

GRE tunnel keepalives

In the event that each GRE tunnel endpoint has keepalive enabled, firewall policies allowing GRE are required in both directions. The policy should be configured as follows (where the IP addresses and interface names are for example purposes only):

```
config firewall policy
  edit < id >
    set srcintf "gre"
    set dstintf "port1"
    set srcaddr "1.1.1.1"
    set dstaddr "2.2.2.2"
    set action accept
    set schedule "always"
    set service "GRE"
  next
end
```

Cisco compatible keep-alive support for GRE

The FortiGate can send a GRE keepalive response to a Cisco device to detect a GRE tunnel. If it fails, it will remove any routes over the GRE interface.

Configuring keepalive query - CLI:

```
config system gre-tunnel
  edit <id>
    set keepalive-interval <value: 0-32767>
    set keepalive-failtimes <value: 1-255>
  next
end
```

GRE tunnel with multicast traffic

If you want multicast traffic to traverse the GRE tunnel, you need to configure a multicast policy as well as enable multicast forwarding.

- To configure a multicast policy, use the `config firewall multicast-policy` command.
- To enable multicast forwarding, use the following commands:

```
config system settings
  set multicast-forward enable
end
```

Using diagnostic commands

There are some diagnostic commands that can provide useful information. When using diagnostic commands, it is best practice that you connect to the CLI using a terminal program, such as puTTY, that allows you to save output to a file. This will allow you to review the data later on at your own speed without worry about missed data as the diag output scrolls by.

Using the packet sniffer - CLI:

1. Enter the following CLI command:

```
diag sniff packet any icmp 4
```

2. Ping an address on the network behind the FortiGate unit from the network behind the Cisco router.

The output will show packets coming in from the GRE interface going out of the interface that connects to the protected network (LAN) and vice versa. For example:

```
114.124303 gre1 in 10.0.1.2 -> 10.11.101.10: icmp: echo request
114.124367 port2 out 10.0.1.2 -> 10.11.101.10: icmp: echo request
114.124466 port2 in 10.11.101.10 -> 10.0.1.2: icmp: echo reply
114.124476 gre1 out 10.11.101.10 -> 10.0.1.2: icmp: echo reply
```

3. Enter CTRL-C to stop the sniffer.

Viewing debug output for IKE - CLI:

1. Enter the following CLI commands

```
diagnose debug application ike -1
diagnose debug enable
```

2. Attempt to use the VPN or set up the VPN tunnel and note the debug output.
3. Enter CTRL-C to stop the debug output.
4. Enter the following command to reset debug settings to default:

```
diagnose debug reset
```

Chapter 14 - Logging and Reporting

This FortiOS Handbook chapter contains the following sections:

[Logging and reporting overview](#) provides general information about logging. We recommend that you begin with this chapter as it contains information for both beginners and advanced users as well. It contains an explanation of log messages, files, and devices, and an overview of the Reporting functions.

[Logging and reporting for small networks](#) provides an overview of setting up a small network for logging, with a look at a possible setup with a backup solution and a customized report.

[Logging and reporting for large networks](#) provides an overview of setting up a larger, enterprise-level network, with configuration of multiple FortiGate units, multiple FortiAnalyzer units as a backup solution, and a sample procedure for creating a more intensive and broad report to suit the larger network.

[Advanced logging](#) provides a series of separate tutorials for possible tasks and procedures an advanced user may want to undertake with their FortiGate-powered network. It contains explanations of advanced backup, logging, and report solutions.

[Troubleshooting and logging](#) provides a short overview of how log messages can be used to identify and solve problems within the network, how to identify and solve logging database issues, and how to solve connection issues between FortiGate and FortiAnalyzer units.

What's new in FortiOS 6.0

The following list contains new Logging & Reporting features added in FortiOS 6.0.

Automatic synchronization of log display location

In previous versions, log display location could differ between Log & Report and FortiView, which could result in empty log screens if the two were not synchronized. Now, both log viewers automatically pick the best available log device. A different log device can be manually selected.

As a result, the associated CLI command `log gui-display location` has been removed.

Improved log messages for SD-WAN link quality changes

FortiOS 6.0 introduces two new log messages:

- 22923: LOG_ID_EVENT_VWL_LQTY_STATUS is created when a member's link quality is changed.
- 22924: LOG_ID_EVENT_VWL_VOLUME_STATUS is used only when `load-balance-mode` is set to `measured-volume-based`. The log is created when a member starts or stops receiving traffic.

Extended UTM logging and improved syslog configuration

Multiple UTM features now have the ability to enable extended logging: WAF, Web Filtering, DLP, AntiVirus.

These new features can be enabled in the CLI:

```
config waf profile
  edit <profile name>
    set extended-log {enable | disable}
  end
config webfilter profile
  edit <profile name>
    set web-extended-log {enable | disable}
    set web-extended-all-action-log {enable | disable}
  end
config dlp sensor
  edit <sensor name>
    set dlp-extended-log {enable | disable}
  end
config antivirus profile
  edit <profile name>
    set av-extended-log {enable | disable}
  end
```

Updated reliable syslog encryption to comply with RFC 5425

In order to align with RFC 5425 (syslog on an encrypted TLS connection over TCP) and general logging security standards for syslog, reliable syslog encryption is customizable in the CLI:

```
config log syslog setting
  set enc-algorithm {high-medium | high | low | disable}
end
```

Also, syslog options for reliable logging transmission have been expanded:

```
config log syslog setting
  set mode {udp | legacy-reliable | reliable}
end
```

See the *FortiOS CLI Reference* for more information about these commands.

Improved log display consistency at high load

Previous versions could display inconsistent log data when using Drill Down charts and when navigating between different log tables (in both **Log & Report** and **FortiView**). The maximum number of records now varies based on length that logs are kept, relative to device model size. Record numbers are configurable in `config report setting`.

Log database queries used to collect **Top Sources** and **Top Destinations** data are significantly more efficient due to improved indexing speed.

Logging and reporting overview

Logging and reporting in FortiOS can help you in determining what is happening on your network, as well as informing you of certain network activity, such as detection of a virus or IPsec VPN tunnel errors. Logging and reporting go hand in hand, and can become a valuable tool for information as well as helping to show others the activity that is happening on the network.

This section explains logging and reporting features that are available in FortiOS, and how they can be used to help you manage or troubleshoot issues. This includes how the FortiGate unit records logs, what a log message is, and what the log database is.

What is logging?

Logging records the traffic passing through the FortiGate unit to your network and what action the FortiGate unit took during its scanning process of the traffic. This recorded information is called a log message.

After a log message is recorded, it is stored within a log file which is then stored on a log device. A log device is a central storage location for log messages. The FortiGate unit supports several log devices, such as FortiAnalyzer units, the FortiCloud service, and Syslog servers. A FortiGate unit's system memory and local disk can also be configured to store logs, and because of this, are also considered log devices.

You must subscribe to FortiCloud before you will be able to configure the FortiGate unit to send logs to a FortiCloud server.

When the recorded activity needs to be read in a more human way, the FortiGate unit can generate a Report. A report gathers all the log information that is needed for the report, and presents it in a graphical format, with customizable design and automatically generated charts. Reports can be used to present a graphical representation of what is going on in the network. Reports can also be generated on a FortiAnalyzer unit; if you want to generate reports on a FortiAnalyzer, see the [FortiAnalyzer Setup and Administration Guide](#) to help you create and generate those reports.

How the FortiGate unit records log messages

The FortiGate unit records log messages in a specific order, storing them on a log device. The order of how the FortiGate unit records log messages is as follows:

1. Incoming traffic is scanned.
2. During the scanning process, the FortiGate unit performs necessary actions, and simultaneously records the actions and results.
3. Log messages are sent to the log device.

Example: How the FortiGate unit records a DLP event

1. The FortiGate unit receives incoming traffic and scans for any matches associated within its firewall policies containing a DLP sensor.
2. A match is found; the DLP sensor, `dlp_sensor`, had a rule within it called All-HTTP with the action Exempt applied to the rule. The sensor also has Enable Logging selected, which indicates to the FortiGate unit that the activity should be recorded and placed in the DLP log file.

3. The FortiGate unit exempts the match, and places the recorded activity (the log message) within the DLP log file.
4. According to the log settings that were configured, logs are stored on the FortiGate unit's local hard drive. The FortiGate unit places the DLP log file on the local hard drive.

FortiOS features available for logging

Logs record FortiGate activity, providing detailed information about what is happening on your network. This recorded activity is found in log files, which are stored on a log device. However, logging FortiGate activity requires configuring certain settings so that the FortiGate unit can record the activity. These settings are often referred to as log settings, and are found in most security profiles, but also in **Log & Report > Log Settings**.

Log settings provide the information that the FortiGate unit needs so that it knows what activities to record. This topic explains what activity each log file records, as well as additional information about the log file, which will help you determine what FortiGate activity the FortiGate unit should record.

Traffic

Traffic logs record the traffic that is flowing through your FortiGate unit. Since traffic needs firewall policies to properly flow through the unit, this type of logging is also referred to as firewall policy logging. Firewall policies control all traffic that attempts to pass through the FortiGate unit, between FortiGate interfaces, zones and VLAN sub-interfaces.

Logging traffic works in the following way:

- firewall policy has logging enabled on it (Log Allowed Traffic)
- packet comes into an inbound interface
- a possible log packet is sent regarding a match in the firewall policy, such as a URL filter
- traffic log packet is sent, per firewall policy
- packet passes and is sent out an interface

Traffic log messages are stored in the traffic log file. Traffic logs can be stored any log device, even system memory.

All security profile-related logs are now tracked within the Traffic logs, as of FortiOS 5.0, so all forward traffic can be searched in one place, such as if you are looking to see all activity from a particular address, security feature or traffic. Security profile logs are still tracked separately in the **Security Log** section, which only appears when logs exist.

If you have enabled and configured WAN Optimization, you can enable logging of this activity in the CLI using the `config wanopt setting` command. These logs contain information about WAN Optimization activity and are found in the traffic log file. When configuring logging of this activity, you must also enable logging within the security policy itself, so that the activity is properly recorded.

Sniffer

The Sniffer log records all traffic that passes through a particular interface that has been configured to act as a One-Armed Sniffer, so it can be examined separately from the rest of the Traffic logs.

Other traffic

The traffic log also records interface traffic logging, which is referred to as Other Traffic. Other Traffic is enabled only in the CLI. When enabled, the FortiGate unit records traffic activity on interfaces as well as firewall policies.

Logging Other Traffic puts a significant system load on the FortiGate unit and should be used only when necessary.

Logging other traffic works in the following way:

- firewall policy has logging enabled on it (Log Allowed Traffic) and other-traffic
- packet comes into an interface
- interface log packet is sent to the traffic log that is enabled on that particular interface
- possible log packet is sent regarding a match in the firewall policy, such as URL filter
- interface log packet is sent to the traffic log if enabled on that particular interface
- packet passes and is sent out an interface
- interface log packet is sent to traffic (if enabled) on that particular interface

Event

The event log records administration management as well as FortiGate system activity, such as when a configuration has changed, admin login, or high availability (HA) events occur. Event logs are an important log file to record because they record FortiGate system activity, which provides valuable information about how your FortiGate unit is performing.

Event logs help you in the following ways:

- keeping track of configuration setting changes
- IPsec negotiation, SSL VPN and tunnel activity
- quarantine events, such as banned users
- system performance
- HA events and alerts
- firewall authentication events
- wireless events on models with WiFi capabilities
- activities concerning modem and internet protocols L2TP, PPP and PPPoE
- VIP activities
- AMC disk's bypass mode
- VoIP activities that include SIP and SCCP protocols.

As of 5.4, every 'execute' CLI command now generates an 'audit' event log, allowing you to track configuration changes. You can enable/disable this feature in the CLI:

```
config system global
    set cli-audit-log [enable|disable]
end
```

The FortiGate unit records event logs only when events are enabled.

Traffic shaping

Traffic shaping, per-IP traffic shaping and reverse direction traffic shaping settings can be applied to a firewall policy, appearing within the traffic log messages.

By enabling this feature, you can see what traffic shaping, per-IP traffic shaping and reverse direction traffic shaping settings are being used.

Data Leak Prevention

Data Leak Prevention logs, or DLP logs, provide valuable information about the sensitive data trying to get through to your network as well as any unwanted data trying to get into your network. The DLP rules within a DLP sensor can log the following traffic types:

- email (SMTP, POP3 or IMAP; if SSL content SMTPS, POP3S, and IMAPS)
- HTTP
- HTTPS
- FTP
- NNTP
- IM

A DLP sensor must have log settings enabled for each DLP rule and compound rule, as well as applied to a firewall policy so that the FortiGate unit records this type of activity. A DLP sensor can also contain archiving options, which these logs are then archived to the log device.

NAC Quarantine

Within the DLP sensor, there is an option for enabling NAC Quarantine. The NAC Quarantine option allows the FortiGate unit to record details of DLP operation that involve the ban and quarantine actions, and sends these to the event log file. The NAC Quarantine option must also be enabled within the Event Log settings. When enabling NAC quarantine within a DLP Sensor, you must enable this in the CLI because it is a CLI-only command.

Media Access Control (MAC) address

MAC address logs provide information about MAC addresses that the FortiGate unit sees on the network as well as those removed from the network. These log messages are stored in the event log (as subtype network; you can view these log messages in **Log & Report > System Events**) and are, by default, disabled in the CLI. You can enable logging MAC addresses using the following command syntax:

```
config log setting
    set neighbor-event enable
end
```

When enabled, a new log message is recorded every time a MAC address entry is added to the ARP table, and also when a MAC address is removed as well. A MAC address log message is also recorded when MAC addresses are connected to the local switch, or from a FortiAP or FortiSwitch unit.

Application control

Application control logs provide detailed information about the traffic that internet applications such as Skype are generating. The application control feature controls the flow of traffic from a specific application, and the FortiGate unit examines this traffic for signatures that the application generates.

The log messages that are recorded provide information such as the type of application being used (such as P2P software), and what type of action the FortiGate unit took. These log messages can also help you to determine the top ten applications that are being used on your network. This feature is called application control monitoring and you can view the information from a widget on the Executive Summary page.

The application control list that is used must have logging enabled within the list, as well as logging enabled within each application entry. Each application entry can also have packet logging enabled. Packet logging for application control records the packet when an application type is identified, similar to IPS packet logging.

Logging of application control activity can only be recorded when an application control list is applied to a firewall policy, regardless of whether or not logging is enabled within the application control list.

Antivirus

Antivirus logs are recorded when, during the antivirus scanning process, the FortiGate unit finds a match within the antivirus profile, which includes the presence of a virus or grayware signature. Antivirus logs provide a way to understand what viruses are trying to get in, as well as additional information about the virus itself, without having to go to the FortiGuard Center and do a search for the detected virus. The link is provided within the log message itself.

These logs provide valuable information such as:

- the name of the detected virus
- the name of the oversized file or infected file
- the action the FortiGate unit took, for example, a file was blocked
- URL link to the FortiGuard Center which gives detailed information about the virus itself

The antivirus profile must have log settings enabled within it so that the FortiGate unit can record this activity, as well as having the antivirus profile applied to a firewall policy.

Web filter

Web filter logs record HTTP traffic activity. These log messages provide valuable and detailed information about this particular traffic activity on your network. Web filtering activity is important to log because it can inform you about:

- what types of web sites employees are accessing
- users attempting to access banned web sites and how often this occurs
- network congestion due to employees accessing the Internet at the same time
- web-based threats resulting from users visiting non-business-related web sites

Web Filter logs are an effective tool to help you determine if you need to update your web filtering settings within a web filter profile due to unforeseen threats or network congestion. These logs also inform you about web filtering quotas that have been configured for filtering HTTP traffic.

You must configure logging settings within the web filter profile and apply the filter to a firewall policy so that the FortiGate unit can record the activity.

IPS (attack)

IPS logs, also referred to as attack logs, record attacks that occurred against your network. Attack logs contain detailed information about whether the FortiGate unit protected the network using anomaly-based defense settings or signature-based defense settings, as well as what the attack was.

The IPS or attack log file is especially useful because the log messages that are recorded contain a link to the FortiGuard Center, where you can find more information about the attack. This is similar to antivirus logs, where a link to the FortiGuard Center is provided as well that informs you of the virus that was detected by the FortiGate unit.

An IPS sensor with log settings enabled must be applied to a firewall policy so that the FortiGate unit can record the activity.

Packet logs

When you enable packet logging within an IPS signature override or filter, the FortiGate unit examines network packets, and if a match is found, saves them to the attack log. Packet logging is designed to be used as a diagnostic tool that can focus on a narrow scope of diagnostics, rather than a log that informs you of what is occurring on your network.

You should use caution when enabling packet logging, especially within IPS filters. Filter configuration that contains thousands of signatures could potentially cause a flood of saved packets, which would take up a lot of storage space on the log device. It would also take a great deal of time to sort through all the log messages, as well as consume considerable system resources to process.

You can archive packets, but you must enable this option on the Log Settings page. If your log configuration includes multiple FortiAnalyzer units, packet logs are only sent to the primary (first) FortiAnalyzer unit. Sending packet logs to the other FortiAnalyzer units is not supported.

Email filter

Email filter logs, also referred to as spam filter logs, record information regarding the content within email messages. For example, within an email filter profile, a match is found that finds the email message to be considered spam.

Email filter logs are recorded when the FortiGate unit finds a match within the email filter profile and logging settings are enabled within the profile.

If you are using a Banned Words List for email filtering, note that the filter pattern number is only recorded when the source email address contains a banned word.

Archives (DLP)

Recording DLP logs for network use is called DLP archiving. The DLP engine examines email, FTP, IM, NNTP, and web traffic. Archived logs are usually saved for historical use and can be accessed at any time. IPS packet logs can also be archived, within the Log Settings page.

You can start with the two default DLP sensors that have been configured specifically for archiving log data, Content_Archive and Content_Summary. They are available in **Security Profiles > Data Leak Prevention**. Content_Archive provides full content archiving, while Content_Summary provides summary archiving. For more information about how to configure DLP sensors, see the Security Features chapter of the FortiOS Handbook.

You must enable the archiving to record log archives. Logs are not archived unless enabled, regardless of whether or not the DLP sensor for archiving is applied to the firewall policy.

Network scan

Network scan logs are recorded when a scheduled scan of the network occurs. These log messages provide detailed information about the network's vulnerabilities regarding software, as well as the discovery of any further vulnerabilities.

A scheduled scan must be configured and logging enabled within the Event Log settings, for the FortiGate unit to record these log messages.

Log messages

Log messages are recorded by the FortiGate unit, giving you detailed information about the network activity. Each log message has a unique number that helps identify it, as well as containing fields; these fields, often called log fields, organize the information so that it can be easily extracted for reports.

These log fields are organized in such a way that they form two groups: the first group, made up of the log fields that come first, is called the log header. The log header contains general information, such as the unique log identification and date and time that indicates when the activity was recorded. The log body is the second group, and contains all the other information about the activity. There are no two log message bodies that are alike, however, there may be fields common to most log bodies, such as the `srcintf` or `identidix` log fields.

The log header also contains information about the log priority level which is indicated in the `level` field. The priority level indicates the immediacy and the possible repercussions of the logged action. For example, if the field contains 'alert', you need to take immediate action with regards to what occurred. There are six log priority levels.

The log severity level is the level at and above which the FortiGate unit records logs. The log severity level is defined by you when configuring the logging location. The FortiGate unit will log all messages at and above the priority level you select. For example, if you select Error, the unit will log only Error, Critical, Alert, and Emergency level messages.

Log priority levels

Levels	Description
0 - Emergency	The system has become unstable.
1 - Alert	Immediate action is required.
2 - Critical	Functionality is affected.
3 - Error	An error condition exists and functionality could be affected.
4 - Warning	Functionality could be affected.
5 - Notification	Information about normal events.
6 - Information	General information about system operations.

The Debug priority level, not shown above, is rarely used. It is the lowest log priority level and usually contains some firmware status information that is useful when the FortiGate unit is not functioning properly.

Example log header fields

Log header	
date=(2010-08-03)	The year, month and day of when the event occurred in yyyy-mm-dd format.

Log header	
time=(12:55:06)	The hour, minute and second of when the event occurred in the format hh:mm:ss.
log_id=(2457752353)	A five or ten-digit unique identification number. The number represents that log message and is unique to that log message. This ten-digit number helps to identify the log message.
type=(dlp)	The section of system where the event occurred.
subtype=(dlp)	The subtype category of the log message.
level=(notice)	The priority level of the event. See the table above.
vd=(root)	The name of the virtual domain where the action/event occurred in. If no virtual domains exist, this field always contains root.

Example log body fields

Log body	
policyid=(1)	The ID number of the firewall policy that applies to the session or packet. Any policy that is automatically added by the FortiGate will have an index number of zero.
identidx=(0)	The identity-based policy identification number. This field displays zero if the firewall policy does not use an identity-based policy; otherwise, it displays the number of the identity-based policy entry that the traffic matched. This number is not globally unique, it is only locally unique within a given firewall policy.
sessionid=(311)	The serial number of the firewall session of which the event happened.
srcip=(10.10.10.1)	The source IP address.
srcport=(1190)	The source port number.
srcintf=(internal)	The source interface name.
dstip=(192.168.1.122)	The destination IP address.
dstport=(80)	The destination port number.
dstintf=(wan1)	The destination interface name.
service=(https)	The IP network service that applies to the session or packet. The services displayed correspond to the services configured in the firewall policy.
status=(detected)	The action the FortiGate unit took.

Log body	
hostname=(example.com)	The home page of the web site.
url=(/image/trees_pine_forest/)	The URL address of the web page that the user was viewing.
msg=(data leak detected (Data Leak Prevention Rule matched))	Explains the FortiGate activity that was recorded. In this example, the data leak that was detected matched the rule, All-HTTP, in the DLP sensor.
rulename=(All-HTTP)	The name of the DLP rule within the DLP sensor.
action=(log-only)	The action that was specified within the rule. In some rules within sensors, you can specify content archiving. If no action type is specified, this field display log-only.
severity=(1)	The level of severity for that specific rule.

Logs from other devices, such as the FortiAnalyzer unit and Syslog server, contain a slightly different log header. For example, when viewing FortiGate log messages on the FortiAnalyzer unit, the log header contains the following log fields when viewed in the Raw format:

```
itime=1302788921 date=20110401 time=09:04:23 devname=FG50BH3G09601792 device_
id=FG50BH3G09601792 log_id=0100022901 type=event subtype=system level=notice vd=root
```

The log body contains the rest of the information of the log message, and this information is unique to the log message itself.

For detailed information on all log messages, see the *FortiGate Log Message Reference*.

Explanation of a debug log message

Debug log messages are only generated if the log severity level is set to Debug. The Debug severity level is the lowest log severity level and is rarely used. This severity level usually contains some firmware status information that is useful when the FortiGate unit is not functioning properly. Debug log messages are generated by all types of FortiGate features.

The following is an example of a debug log message:

```
date=2010-01-25 time=17:25:54 logid=9300000000 type=webfilter subtype=urlfilter
level=debug msg="found in cache"
```

Example of a Debug log message

Debug log	
date=(2010-01-25)	The year, month and day of when the event occurred in the format yyyy-mm-dd.
time=(17:25:54)	The hour, minute and second of when the event occurred in the format hh:mm:ss.

Debug log	
logid=(930000000000)	A ten-digit unique identification number. The number represents that log message and is unique to that log message. This ten-digit number helps to identify the log message.
type=(webfilter)	The section of system where the event occurred. There are eleven log types in FortiOS 4.0.
subtype=(urlfilter)	The subtype of the log message. This represents a policy applied to the FortiGate feature in the firewall policy.
level=(debug)	The priority level of the event. There are six priority levels to specify.
msg=("found in cache")	Explains the activity or event that the FortiGate unit recorded.

Viewing log messages and archives

Depending on the log device, you may be able to view logs within the web-based manager or CLI on the FortiGate unit. If you have configured a FortiAnalyzer unit, local hard disk, or system memory, you can view log messages from within the web-based manager or CLI. If you have configured either a Syslog or WebTrends server, you will not be able to view log messages from the web-based manager or CLI. There is also no support for viewing log messages stored on a FortiCloud server, from the FortiGate unit's web-based manager or CLI.

You do not have to view log messages from only the web-based manager. You can view log messages from the CLI as well, using the `execute log display` command. This command allows you to see specific log messages that you already configured within the `execute log filter` command. The `execute log filter` command configures what log messages you will see, how many log messages you can view at one time (a maximum of 1000 lines of log messages), and the type of log messages you can view. For more information about viewing log messages in the CLI, see "Viewing logs from the CLI".

There are two log viewing options in FortiOS: Format and Raw. The Raw format displays logs as they appear within the log file. You can view log messages in the Raw format using the CLI or a text editor, such as Notepad. Format is in a more human-readable format, and you can easily filter information when viewing log messages this way. The Format view is what you see when viewing logs in the web-based manager.

When you download the log messages from within the log message page (for example, **Log & Report > Forward Traffic**), you are downloading log messages in the Raw format.

Viewing log messages in detail

From any log page, you can view detailed information about the log message in the log viewer table, located (by default) at the bottom of the page. Each page contains this log viewer table. The Log Viewer Table can contain the Archive tab, which allows you to see the archived version of the log message. The Archive tab only displays the archived log's details if archiving is enabled and logs are being archived by the FortiGate unit, but archived logs will also be recorded when using a FortiAnalyzer unit or the FortiCloud service.

When you are viewing traffic log messages, some of the categories (such as 'Application Name') have entries that can be selected to open a dialog box containing FortiGuard information about the entry. From within the dialog box, you can select the Reference link and go directly to the corresponding FortiGuard page, which contains additional information.

Viewing logs in Raw format allows you to view all log fields at once, as well as have a log file available regardless of whether you are archiving logs or not. You download the log file by selecting **Download Log**. The log file is named in the following format: <log_type><log_location><log_date/time>.<log_number>.log. For example, SystemEventLog-disk-2012-09-19T12_13_46.933949.log, which is an event log. The time period is the day and month of when the log was downloaded, not the time period of the log messages within the file itself.

Quarantine

Within the Log & Report menu, you can view detailed information about each quarantined file. The information can either be sorted or filtered, depending on what you want to view.

You must enable quarantine settings within an antivirus profile and the destination must be configured in the CLI using the `config antivirus quarantine` command. The destination can be either a FortiAnalyzer unit or local disk.

Sort the files by file name, date, service, status, duplicate count (DC), or time to live (TTL). Filter the list to view only quarantined files with a specific status or from a specific service.

The file quarantine list displays the following information about each quarantined file.

Quarantine page

Lists all files that are considered quarantined by the unit. On this page you can filter information so that only specific files are displayed on the page.

GUI Item	Description
Source	Either FortiAnalyzer or Local Disk , depending where you configure to quarantined files to be stored.
Sort by	Sort the list. Choose from: Status , Service , File Name , Date , TTL , or Duplicate Count . Select Apply to complete the sort.
Filter	<p>Filter the list. Choose either Status (infected, blocked, or heuristics) or Service (IMAP, POP3, SMTP, FTP, HTTP, MM1, MM3, MM4, MM7, IM, or NNTP). Select Apply to complete the filtering. Heuristics mode is configurable through the CLI only.</p> <p>If your unit supports SSL content scanning and inspection Service can also be IMAPS, POP3S, SMTPS, or HTTPS. For more information, see the Security Features chapter of the FortiOS Handbook.</p>
Apply	Select to apply the sorting and filtering selections to the list of quarantined files.
Delete	Select to delete the selected files.
Page Controls	Use the controls to page through the list.

GUI Item	Description
Remove All Entries	Removes all quarantined files from the local hard disk. This icon only appears when the files are quarantined to the hard disk.
File Name	The file name of the quarantined file. When a file is quarantined, all spaces are removed from the file name, and a 32-bit checksum is performed on the file. The checksum appears in the replacement message but not in the quarantined file. The file is stored on the FortiGate hard disk with the following naming convention: <32bit_CRC>.<processed_filename> For example, a file named Over Size.exe is stored as 3fc155d2.oversize.exe.
Date	The date and time the file was quarantined, in the format dd/mm/yyyy hh:mm. This value indicates the time that the first file was quarantined if duplicates are quarantined.
Service	The service from which the file was quarantined (HTTP, FTP, IMAP, POP3, SMTP, MM1, MM3, MM4, MM7, IM, NNTP, IMAPS, POP3S, SMTPS, or HTTPS).
Status	The reason the file was quarantined: infected , heuristics , or blocked .
Status Description	Specific information related to the status, for example, "File is infected with "W32/Klez.h"" or "File was stopped by file block pattern."
DC	Duplicate count. A count of how many duplicates of the same file were quarantined. A rapidly increasing number can indicate a virus outbreak.
TTL	Time to live in the format hh:mm. When the TTL elapses, the FortiGate unit labels the file as EXP under the TTL heading. In the case of duplicate files, each duplicate found refreshes the TTL. The TTL information is not available if the files are quarantined on a FortiAnalyzer unit.
Upload status	Y indicates the file has been uploaded to Fortinet for analysis, N indicates the file has not been uploaded. This option is available only if the FortiGate unit has a local hard disk.
Download	Select to download the corresponding file in its original format. This option is available only if the FortiGate unit has a local hard disk.
Submit	Select to upload a suspicious file to Fortinet for analysis. This option is available only if the FortiGate unit has a local hard disk.

Customizing the display of log messages on the web-based manager

Customizing log messages on the web-based manager allows you to remove or add columns from the page and filter the information that appears. For example, you can view only log messages that appeared on December 4, between the hours of 8:00 and 8:30 am.

1. Select the submenu in **Log & Report** in which you want to customize the display of log messages, such as **Log & Report > Forward Traffic**.
2. Right click on the title bar at the top of any column, and uncheck a column title such as **Date/Time** to remove it from the interface. Check other columns to add them to the interface. When you are finished, click outside the menu and the page will refresh with the new column settings in place.
3. Choose a column you'd like to filter, and select the funnel icon next to the title of the column. For example, select the funnel in the Src (Source) column. In the text field, enter the source IP address 1.1.1.1 and then select the check box beside **NOT**.
This filters out the all log messages that have the 1.1.1.1 source IP address in the source IP log field, such as the ones generated when running log tests in the CLI.
4. Select **OK** to save the customize settings, and then view the log messages on the page.
Log messages that originate from the 1.1.1.1 source address will no longer appear in the list.

How to download log messages and view them from on a computer

After recording some activity, you can download log messages to view them from a computer. This is can be very useful when in a remote location, or if you want to view log messages at your convenience, or to view packet logs or traffic logs.

1. In Log & Report, select the submenu that you want to download log messages from.
For example, **Log & Report > Forward Traffic**.
2. Select the **Download Log** option and save the log file to your computer.
The log file will be downloaded like any other file. Log file names contain their log type and date in the name, so it is recommended to create a folder in which to archive your log messages, as they can be sorted easily.
3. Open a text editor such as Notepad, open the log file, and then scroll to view all the log messages.
You can easily search or scroll through the logs to see the information that is available.

Log files and types

As the log messages are being recorded, log messages are also being put into different log files. The log file contains the log messages that belong to that log type, for example, traffic log messages are put in the traffic log file.

When downloading the log file from within **Log & Report**, the file name indicates the log type and the device on which it is stored, as well as the date, time, and a unique id for that log.

This name is in the format <logtype> - <logdevice> - <date> T <time> . <id>.log.

For example, AntiVirusLog-disk-2012-09-13T11_07_57.922495.log.

Below, each of the different log files are explained. Traffic and Event logs come in multiple types, but all contain the base type such as 'Event' in the filename.

Log Types based on network traffic

Log Type	Description
Traffic	The traffic logs records all traffic to and through the FortiGate interface. Different categories monitor different kinds of traffic, whether it be forward, local, or sniffer.
Event	The event logs record management and activity events within the device in particular areas: System, Router, VPN, User, Endpoint, HA, WAN Opt./Cache, and WiFi. For example, when an administrator logs in or logs out of the web-based manager, it is logged both in System and in User events.
Antivirus	The antivirus log records virus incidents in Web, FTP, and email traffic.
Web Filter	The web filter log records HTTP FortiGate log rating errors including web content blocking actions that the FortiGate unit performs.
Application Control	The application log records application usage, monitoring or blocking as configured in the security profiles.
Intrusion	The intrusion log records attacks that are detected and prevented by the FortiGate unit.
Email Filter	The email filter log records blocking of email address patterns and content in SMTP, IMAP, and POP3 traffic.
Vulnerability Scan	The Vulnerability Scan (Netscan) log records vulnerabilities found during the scanning of the network.
Data Leak Prevention	The Data Leak Prevention log records log data that is considered sensitive and that should not be made public. This log also records data that a company does not want entering their network.
VoIP	The VoIP log records VoIP traffic and messages. It only appears if VoIP is enabled on the Administrator Settings page.

Log database and datasets

The log database, also known as the SQL log database, is used to store logs on FortiGate units that have a built-in hard disk. The log database uses Structured Query Language (SQL), specifically it uses SQLite which is an embedded Relational Database Management System (RDBMS).

If you have disabled SQL logging and have factory defaults on the FortiGate unit, and then you upgrade the firmware, the upgrade will automatically disable SQL logging. When this occurs, you must re-enable SQL logging manually.

The FortiGate unit creates a database table for each log type, when log data is recorded. If the FortiGate unit is not recording log data, it does not create log tables for that device.

If you want to view the size of the database, as well as the log database table entries, use the `get report sql status` command. This command displays the amount of free space that is available as well as the first and last log database entry time and date.

The output of the `get report sql status` command contains information similar to the following:

```
Database size: 294912
Free size in database: 0
Database Page Size: 8192
Entry number:
Event: 49
Traffic: 370
Attack: 2
AntiVirus: 4
WebFilter: 254
AntiSpam: 2
Netscan: 18
Total: 699
First entry time: 2012-09-10 11:41:02
Last entry time: 2012-09-13 02:59:59
```

The log database is not only used to store logs, but also used to extract the information for reports. Reports are built from datasets, which are SQL statements that tell the FortiGate unit how to extract the information from the database. You can create your own datasets; however, SQL knowledge is required. Default datasets are available for reports.

Notifications about network activity

Alert email messages provide notification about activities or events logged. These email messages also provide notification about log severities that are recorded, such as a critical or emergency.

You can send alert email messages to up to three email addresses. Alert messages are also logged and can be viewed from the Event Log menu, in the System Event log file.

You can use the alert email feature to monitor logs for log messages, and to send email notification about a specific activity or event logged. For example, if you require notification about administrators logging in and out, you can configure an alert email that is sent whenever an administrator logs in and out. You can also base alert email messages on the severity levels of the logs.

Before configuring alert email, you must configure at least one DNS server if you are configuring with an Fully Qualified Domain Server (FQDN). The FortiGate unit uses the SMTP server name to connect to the mail server, and must look up this name on your DNS server. You can also specify an IP address.

The default minimum log severity level is Alert. If the FortiGate unit collects more than one log message before an interval is reached, the FortiGate unit combines the messages and sends out one alert email.

How to configure email notifications

The following explains how to configure an alert email notification for IPsec tunnel errors, firewall authentication failure, configuration changes and FortiGuard license expiry.

1. In **System > Advanced**, under **Email Service**, configure the SMTP server.

The SMTP server settings allow the FortiGate unit to know exactly where the email will be sent from, as well as who to send it to. The SMTP server must be a server that does not support SSL/TLS connections; if the SMTP server does, the alert email configuration will not work. The FortiGate unit does not currently support SSL/TLS

connections for SMTP servers.

2. In **Log & Report > Alert E-mail**, enter the source email in the Email From field, and up to three target addresses in the Email To fields.
3. Below the email entry, you can configure the email responses. By default, the **Send alert email for the following** is enabled. Select the check boxes beside **IPsec tunnel errors**, **Configuration changes** and **Firewall authentication failure**.

These alerts will be sent to the email address specified when the trigger occurs. For example, a user attempts to connect to the branch office of the company but cannot; the FortiGate unit detects an IPsec tunnel error, records the event, and then sends the notice to the email address specified in the SMTP server settings.

4. Select **FortiGuard license expiry time**: and then enter 10 so that the email notification will be sent ten days prior to the FortiGuard license expiration.
You can choose up to 100 days prior to when the license will expire. The default time is 15 days. By using this alert email notification, you can easily know when to send an re-registration request long before the expiry.

Log devices

The FortiGate unit supports a variety of log devices, including the FortiCloud service and FortiAnalyzer units. This provides greater flexibility not only when choosing a log device, but also when your logging requirements need updating.

When you have developed a plan that meets your logging needs and requirements, you need to select the log device that is appropriate for that plan. A log device must be able to store all the logs you need, and if you require archiving those logs, you must consider what log devices support this option.

During this process of deciding what log device meets your needs and requirements, you must also figure out how to provide a backup solution in the event the log device that the FortiGate unit is sending logs to has become unavailable. A backup solution should be an important part of your log setup because it helps you to maintain all logs and prevents lost logs, or logs that are not sent to the log device. For example, a daily backup of log files to the FortiAnalyzer unit occurs at 5 pm.

Log devices provide a central location for storing logs recorded by the FortiGate unit. The following are log devices that the FortiGate unit supports:

- FortiGate system memory
- Hard disk or AMC
- SQL database (for FortiGate units that have a hard disk)
- FortiAnalyzer unit
- FortiCloud service
- Syslog server

These log devices, except for the FortiGate system memory and local hard disk, can also be used as a backup solution. For example, you can configure logging to the FortiGate unit's local disk, but also configure logging to a FortiCloud server and archive logs to both the FortiCloud server and a FortiAnalyzer unit.

If you are formatting a disk that contains more than just logs, all information on the disk will be lost.

FortiGate unit's system memory and hard disk

The FortiGate unit's system memory and hard disk can store all log types, including log archives and traffic logs. Traffic logs and log archives are larger files, and need a lot of room when being logged by the FortiGate unit.

When the system memory is full, the FortiGate unit overwrites the oldest messages, and all log messages stored in memory are cleared when the FortiGate unit restarts. By default, logging to memory is enabled. This means that most of the time you will only need to modify the default settings to your network logging requirements. Real-time logging occurs whenever memory logging is enabled, and is enabled by default. Real-time logging means that the activity is being recorded as it happens.

All FortiGate units 100D and larger are capable of disk logging, but it is disabled by default, as it is not recommended. For flash memory-based units, constant rewrites to flash drives can reduce the lifetime and efficiency of the memory. For hard-disk units, it can affect performance under heavy strain. Therefore, disk logging must be manually enabled in the CLI under `config log disk setting` to appear in the interface at all.

Models without a hard disk are not recommended for disk logging. For all units, disk logging must be enabled in the CLI. For some low-end and older models, disk logging is unavailable. Check a product's Feature Matrix for more information. In either case, Fortinet recommends using either a FortiAnalyzer unit or the FortiCloud service.

Local disk or memory logging is not required for you to configure logging to a FortiAnalyzer unit.

If you are registered with the FortiCloud service, your unit will log both locally and to the service by default. In order to configure the rate and time of uploads to the service, you must register a contract account for the FortiCloud service, which will also grant you additional space.

FortiAnalyzer unit

The FortiAnalyzer unit can log all FortiGate features, which includes log archives. You can also configure the FortiGate unit to upload logs to the FortiAnalyzer unit at a scheduled time.

Encryption of the logs is supported by default and logs are sent using SSL VPN. When the FortiAnalyzer and FortiGate units have SSL encryption, both must choose a setting for the `enc-algorithm` command (CLI) for encryption to take place. By default, this is enabled and the default setting is a SSL communication with high and medium encryption algorithms. The setting that you choose must be the same for both.

FortiGate units can support logging to multiple FortiAnalyzer units. This logging solution is a backup redundancy solution, since logs are sent to all three units and whenever one of the FortiAnalyzer units fails, the others still carry on storing logs.

If you are using evaluation software FortiGate and FortiAnalyzer-VM images, you will only be able to use low-level encryption.

The FortiGate unit can also connect to a FortiAnalyzer unit using Automatic Discovery. Automatic Discovery is a method of establishing a connection to a FortiAnalyzer unit by using the FortiGate unit to find a FortiAnalyzer unit on the network. The Fortinet Discovery Protocol (FDP) is used to locate the FortiAnalyzer unit. Both the FortiGate and FortiAnalyzer units must be on the same subnet to use FDP, and they must also be able to connect using UDP.

When you enable automatic discovery in the CLI, the FortiGate unit uses HELLO packets to locate any FortiAnalyzer units that are available on the network within the same subnet. When the FortiGate unit discovers a

FortiAnalyzer unit, the FortiGate unit automatically enables logging to the FortiAnalyzer unit and begins sending log data.

Syslog server

A Syslog server is a remote computer running syslog software. Syslog is a standard for forwarding log messages in an IP network, and can be used when considering a log backup solution for your network logging requirements. Logs that are generated in real-time are sent to the syslog server in real time with no queueing, so it can be an ideal solution for comprehensive logging, or collecting logs for later systematic analysis.

FortiGate units support the reliable syslog feature, which is based on RFC 3195. Reliable syslog logging uses TCP, which ensures that connections are set up, including that packets are transmitted.

There are several profiles available for reliable syslog, but only the RAW profile is currently supported on the FortiGate units. The RAW profile is designed to provide a high-performance, low-impact footprint using essentially the same format as the existing UDP-based syslog service. The reliable syslog feature is available on FortiGate units running FortiOS 4.0 MR1 and higher.

When enabling the reliable syslog (available only in the CLI), TCP is used. The feature is disabled by default, and when enabled, the FortiGate unit automatically changes the port number to TCP 601. This is based on RFC 3195. The default port for syslog is port 514.

If you are using the local hard disk on a device for WAN Optimization, it will not prevent you from logging to remote FortiAnalyzer devices or Syslog servers. Some models have two hard disks, allowing both local logging and Wan Opt.

If you have Virtual Domains configured, each VDOM may only be assigned one FortiAnalyzer device and one Syslog server, by overriding the global configuration. The root VDOM is not limited in this way.

How to choose a log device for your network topology

When planning the log requirements, you must also consider your network's topology and whether archiving is required, such as if there is a legal requirement to keep a historical record of network activity. The following explains what steps to take when choosing a log device for your specific network topology.

1. What is the scope of your network topology?

If it is a SOHO/SMB network, then logging to the FortiGate unit's local hard disk or the default FortiCloud service would be efficient. If the network topology is a large enterprise, you will need FortiAnalyzer units, a FortiCloud contract, Syslog servers, or any combination.

2. Is archiving required?

If the network activity that is being logged needs to be archived, then, depending on your network topology, you would choose a FortiAnalyzer unit. FortiAnalyzer units store archives in the same way that FortiGate units do, but are able to store large amounts of logs and archives.

3. When troubleshooting, you may want to log a larger amount of traffic; how much storage space will you need?

Logs can be configured to roll, which is similar to zipping a file; this will lower the space requirements needed to contain them. You can also download logs from the FortiGate unit and save them on a server or on a computer to view and access later, to prevent them from piling up and being overwritten. If you're regularly logging large amounts of traffic, you should consider a FortiAnalyzer or FortiCloud account.

4. Should I invest in a log device that can grow as my network grows?

All networks grow, so investing in a device that can grow with your network and that can be expanded is a good investment. For example, if you currently have a SOHO/SMB topology, but see growth already starting, a FortiAnalyzer unit would be best. A FortiAnalyzer unit provides ample storage space, and you can add two more FortiAnalyzer units to access additional storage and create a redundancy log backup solution.

How to create a backup solution for logging

The following helps to explain how to create a log backup solution for a small network topology. This example has one FortiAnalyzer unit and a subscription to the FortiCloud Service.

Example of an integrated FortiAnalyzer unit and Syslog servers in a network

1. Log in to the CLI and modify what features will be logged to the FortiAnalyzer unit as well as the settings to the default log device, the FortiGate unit's hard drive.
By default, the FortiGate unit logs to either the system memory or hard drive, whichever is available on the FortiGate unit. Low-end FortiGate units may have logging disabled by default.
2. In the CLI, use the `config log fortianalyzer setting` command to configure logging to the FortiAnalyzer unit.
You can only configure log settings for the FortiAnalyzer unit in the CLI. Configuring to upload logs to a FortiAnalyzer unit can be configured in both the CLI and web-based manager.
3. In the CLI, configure the settings for the Syslog server; also enable reliable syslog as well.
Reliable syslog verifies that logs are sent to the syslog server. When you enable this setting, the default port becomes port 601.

Reports

Reports provide a clear, concise overview of what is happening on your network based on log data, and can be customized to serve different purposes. There are three types of reports supported by the FortiGate: FortiOS Reports, FortiCloud Reports, and FortiAnalyzer Reports.

FortiOS Reports are generated and configured on the FortiGate unit itself, FortiCloud Reports are created and configured on the FortiCloud site and mirrored to the connected FortiGate for viewing, and FortiAnalyzer reports are created and configured on a FortiAnalyzer unit. For more information about those reports, see the FortiAnalyzer Administration Guide.

In order to create FortiOS Reports on a device, disk logging must be enabled. Not all devices are capable of disk logging; check the Feature Matrix to see if your unit has a hard disk. Once disk logging has been enabled, Local Reports can then be enabled in **System > Feature Visibility** in order to view and edit reports.

What are FortiOS reports?

FortiOS reports are created from logs stored on the FortiGate unit's hard drive. These reports, generated by the FortiGate unit itself, provide a central overview of traffic and security features on the FortiGate. A default FortiOS report, called the FortiGate Security Feature Daily Activity Report, is available for you to use or modify to your requirements. The default report compiles security feature activity from various security-related logs, such as virus and attack logs. You can quickly and easily create your own report from within the management interface.

What you can do with the default FortiOS report

On the **Log & Report > Local Reports** page, you can set the frequency and timing of auto-generated reports.

You can select **Run Now** on the **Local Reports** page to immediately create a report with the current layout and design. More complex reports may take longer to generate. After generating a report, you can view it by selecting it from the list below **Run Now**.

Historical reports will be marked as 'Scheduled' if created automatically, or 'On Demand' if created by selecting **Run Now**.

What are FortiCloud reports?

FortiCloud reports are created from logs stored on the FortiCloud log management service. An active FortiCloud Service Subscription is required in order to view, configure, or use these reports. They are generated by FortiCloud according to a schedule you set, and then mirrored to the FortiGate interface and can be viewed at **Log & Report > FortiCloud Reports**, which may not appear in the interface until a report is created. If you wish to configure the report design or structure, you will have to do so from the FortiCloud portal website.

See the FortiCloud Administration Guide for more information about using and configuring FortiCloud reports.

Best practices: Log management

When the FortiGate unit records FortiGate activity, valuable information is collected that provides insight into how to better protect network traffic against attacks, including misuse and abuse. There is a lot to consider before enabling logging on a FortiGate unit, such as what FortiGate activities to enable and which log device is best suited for your network's logging needs. A plan can help you in deciding the FortiGate activities to log, a log device, as well as a backup solution in the event the log device fails.

This plan should provide you with an outline, similar to the following:

- what FortiGate activities you want and/or need logged (for example, security features)
- the logging device best suited for your network structure
- if you want or require archiving of log files
- ensuring logs are not lost in the event a failure occurs.

After the plan is implemented, you need to manage the logs and be prepared to expand on your log setup when the current logging requirements are outgrown. Good log management practices help you with these tasks.

Log management practices help you to improve and manage logging requirements. Logging is an ever-expanding tool that can seem to be a daunting task to manage. The following management practices will help you when issues arise, or your logging setup needs to be expanded.

1. Revisit your plan on a yearly basis to verify that your logging needs are being met by your current log setup. For example, your company or organization may require archival logging, but not at the beginning of your network's lifespan. Archival logs are stored on a FortiGate unit's local hard drive, a FortiAnalyzer unit, or a FortiCloud server, in increasing order of size.
2. Configure an alert message that will notify you of activities that are important to be aware about. For example: if a branch office does not have a FortiGate administrator, you will need to know at all times that the IPsec VPN tunnel is still up and running. An alert email notification message can be configured to send only if IPsec tunnel errors occur.
3. If your organization or company uses peer-to-peer programs such as Skype or other instant messaging software, use the Applications FortiView dashboard, or the Executive Summary's report widget (Top 10 Application Bandwidth Usage Per Hour Summary) to help you monitor the usage of these types of instant messaging software. These widgets can help you in determining how these applications are being used, including if there is any misuse and abuse. Their information is taken from application log messages; however, application log messages should be viewed as well since they contain the most detailed information.
4. Ensure that your backup solution is up-to-date. If you have recently expanded your log setup, you should also review your backup solution. The backup solution provides a way to ensure that all logs are not lost in the event that the log device fails or issues arise with the log device itself.

Logging and reporting for small networks

This section explains how to configure the FortiGate unit for logging and reporting in a small office or SOHO/SMB network. To properly configure this type of network, you will be modifying the default log settings, as well as the default FortiOS report.

The following procedures are examples and can be used to help you when configuring your own network's log topology. Since some of these settings must be modified or enabled or disabled in the CLI, it is recommended to review the FortiGate CLI Reference for any additional information about the commands used herein, as well as any that you would need to use in your own network's log topology.

Modifying default log device settings

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled, except for traffic logging. The default logging location will be either the FortiGate unit's system memory or hard disk, depending on the model. Units with a flash disk are not recommended for disk logging.

Modifying the FortiGate unit's system memory default settings

When the FortiGate unit's default log device is its system memory, the following is modified for a small network topology. The following is an example of how to modify these default settings.

To modify the default system memory settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log memory setting
    set status enable
end
```

3. The following example command syntax modifies which FortiGate features that are enabled for logging:

```
config log memory filter
    set forward-traffic enable
    set local-traffic enable
    set sniffer-traffic enable
    set anomaly enable
    set voip disable
    set multicast-traffic enable
    set dns enable
end
```

Modifying the FortiGate unit's hard disk default settings

When the FortiGate unit's default log device is its hard disk, you need to modify those settings to your network's logging needs so that you can effectively log what you want logged. The following is an example of how to modify these default settings.

To modify the default hard disk settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log disk setting
  set ips-archive disable
  set status enable
  set max-log-file-size 1000
  set storage FLASH
  set log-quota 100
  set report-quota 100
end
```

3. In the CLI, enter the following to disable certain event log messages that you do not want logged:

```
config log eventfilter
  set event enable
  set system enable
  set vpn disable
  set user enable
  set router disable
  set wan-opt disable
end
```

Testing sending logs to the log device

After modifying both the settings and the FortiGate features for logging, you can test that the modified settings are working properly. This test is done in the CLI.

To test sending logs to the log device

1. In the CLI, enter the following command syntax:

```
diag log test
```

When you enter the command, the following appears:

```
generating a system event message with level - warning
generating an infected virus message with level - warning
generating a blocked virus message with level - warning
generating a URL block message with level - warning
generating a DLP message with level - warning
generating an IPS log message
generating an anomaly log message
generating an application control IM message with level - information
generating an IPv6 application control IM message with level - information
generating deep application control logs with level - information
generating an antispam message with level - notification
generating an allowed traffic message with level - notice
generating a multicast traffic message with level - notice
generating a ipv6 traffic message with level - notice
generating a wanopt traffic log message with level - notification
generating a HA event message with level - warning
generating netscan log messages with level - notice
generating a VOIP event message with level - information
generating a DNS event message with level - information
generating authentication event messages
generating a Forticlient message with level - information
```

```
generating a URL block message with level - warning
```

2. In the web-based interface, go to **Log & Report > System Events**, and view the logs to see some of the recently generated test log messages.
You will be able to tell the test log messages from real log messages because they do not have “real” information; for example, the test log messages for the vulnerability scan contain the destination IP address of 1.1.1.1 or 2.2.2.2.

Configuring the backup solution

A backup solution provides a way to ensure logs are not lost. The following backup solution explains logging to a FortiCloud server and uploading logs to a FortiAnalyzer unit. With this backup solution, there can be three simultaneous storage locations for logs, the first being the FortiGate unit itself, the FortiAnalyzer unit and then the FortiCloud server.

Configuring logging to a FortiCloud server

The FortiCloud server can be used as a redundant backup, or your primary logging solution. The following assumes that this service has already been registered, and a subscription has been purchased for expanded space. The following is an example of how these settings are configured for a network's log configuration. You need to have access to both the CLI and the web-based manager when configuring uploading of logs. The upload time and interval settings can be configured in the web-based interface.

To configure logging to the FortiCloud server

1. Go to **Dashboard** and click **Login** next to **FortiCloud** in the **License Information** widget.
2. Enter your username and password, and click **OK**. (Or register, if you have not yet done so.)
3. Logs will automatically be uploaded to FortiCloud as long as your FortiGate is linked to your FortiCloud account.
4. To configure the upload time and interval, go to **Log & Report > Log Settings**.
5. Under the Logging and Archiving header, you can select your desired upload time.

With FortiCloud you can easily store and access FortiGate logs that can give you valuable insight into the health and security of your network.

Configuring uploading logs to the FortiAnalyzer unit

The logs will be uploaded to the FortiAnalyzer unit at a scheduled time. The following is an example of how to upload logs to a FortiAnalyzer unit.

To upload logs to a FortiAnalyzer unit

1. Go to **Log & Report > Log Settings**.
2. In the **Remote Logging and Archiving** section, select the check box beside **Send Logs to FortiAnalyzer/FortiManager**.
3. Select **FortiAnalyzer (Daily at 00:00)**.
4. Enter the FortiAnalyzer unit's IP address in the **IP Address** field.
5. To configure the daily upload time, open the CLI.
6. Enter the following to configure when the upload occurs, and the time when the unit uploads the logs:

```
config log fortianalyzer setting
  set upload-interval {daily | weekly | monthly}
  set upload-time <hh:mm>
```

end

7. To change the upload time, in the web-based manager, select **Change** beside the upload time period, and then make the changes in the Upload Schedule window. Select **OK**.

Testing uploading logs to a FortiAnalyzer unit

You should test that the FortiGate unit can upload logs to the FortiAnalyzer unit, so that the settings are configured properly.

To test the FortiAnalyzer upload settings

1. Go to **Log & Report > Log Settings**.
2. In the **Logging and Archiving** section, under **Send Logs to FortiAnalyzer/FortiManager**, change the time to the current time by selecting **Change**.
For example, the current time is 11:10 am, so **Change** now has the time 11:10.
3. Select **OK**.

The logs will be immediately sent to the FortiAnalyzer unit, and will be available to view from within the FortiAnalyzer's interface.

Logging and reporting for large networks

This section explains how to configure the FortiGate unit for logging and reporting in a larger network, such as an enterprise network. To set up this type of network, you are modifying the default log settings, and you are also modifying the default report.

The following procedures are examples and can be used to help you when configuring your own network's log topology.

Since some of these settings must be modified or enabled or disabled in the CLI, it is recommended to review the FortiGate CLI Reference for any additional information about the commands used herein, as well as any that you would need to use in your own network's log topology.

Modifying default log device settings

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled and well as logging to either the FortiGate unit's system memory or hard disk, depending on the model.

Modifying multiple FortiGate units' system memory default settings

When the FortiGate unit's default log device is its system memory, you can modify it to fit your log network topology. In this topic, the following is an example of how you can modify these default settings.

To modify the default system memory settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log memory setting
    set status enable
end
```
3. Enter the following command syntax to modify the FortiGate features that are enabled for logging:

```
config log memory filter
    set forward-traffic enable
    set local-traffic enable
    set sniffer-traffic enable
    set anomaly enable
    set voip enable
    set multicast-traffic enable
    set dns enable
end
```
4. Repeat steps 2 and 3 for the other FortiGate units.
5. Test the modified settings using the procedure below.

Modifying multiple FortiGate units' hard disk default log settings

You will have to modify each FortiGate unit's hard disk default log settings. The following is an example of how to modify these default settings.

To modify the default hard disk settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log disk setting
  set ips-archive disable
  set status enable
  set max-log-file-size 1000
  set storage Internal
  set log-quota 100
  set report-quota 100
end
```

3. In the CLI, enter the following to disable certain event log messages that you do not want logged:

```
config log eventfilter
  set event enable
  set system enable
  set vpn enable
  set user enable
  set router disable
  set wan-opt disable
end
```

4. Repeat the steps 2 to 4 for the other FortiGate units.
5. Test the modified settings using the procedure below.

Testing the modified log settings

After modifying both the settings and the FortiGate features for logging, you can test that the modified settings are working properly. This test is done in the CLI.

To test sending logs to the log device

1. In the CLI, enter the following command syntax:

```
diag log test
```

When you enter the command, the following appears:

```
generating a system event message with level - warning
generating an infected virus message with level - warning
generating a blocked virus message with level - warning
generating a URL block message with level - warning
generating a DLP message with level - warning
generating an IPS log message
generating an anomaly log message
generating an application control IM message with level - information
generating an IPv6 application control IM message with level - information
generating deep application control logs with level - information
generating an antispam message with level - notification
generating an allowed traffic message with level - notice
generating a multicast traffic message with level - notice
generating a ipv6 traffic message with level - notice
generating a wanopt traffic log message with level - notification
generating a HA event message with level - warning
generating netscan log messages with level - notice
```

```

generating a VOIP event message with level - information
generating a DNS event message with level - information
generating authentication event messages
generating a Forticlient message with level - information
generating a URL block message with level - warning

```

2. In the web-based interface, go to **Log & Report > System Events**, and view the logs to see some of the recently generated test log messages.

You will be able to tell the test log messages from real log messages because they do not have “real” information; for example, the test log messages for the vulnerability scan contain the destination IP address of 1.1.1.1 or 2.2.2.2.

Configuring the backup solution

Even though you are logging to multiple FortiAnalyzer units, this is more of a redundancy solution rather than a complete backup solution in this example.

The multiple FortiAnalyzer units act similar to a HA cluster, since if one FortiAnalyzer unit fails, the others continue storing the logs they receive. In a backup solution, the logs are backed up to another secure location if something happens to the log device.

A good alternate or redundant option is the FortiCloud service, which can provide secure online logging and management for multiple devices.

Configuring logging to multiple FortiAnalyzer units

The following example shows how to configure logging to multiple FortiAnalyzer units. Configuring multiple FortiAnalyzer units is quick and easy; however, you can only configure up to three FortiAnalyzer units per FortiGate unit.

To configure multiple FortiAnalyzer units

1. In the CLI, enter the following command syntax to configure the first FortiAnalyzer unit:

```

config log fortianalyzer setting
    set status enable
    set server 172.20.120.22
    set max-buffer-size 1000
    set buffer-max-send 2000
    set address-mode static
    set conn-timeout 100
    set monitor-keepalive-period 120
    set monitor-failure-retry-period 2000
end

```

2. Disable the features that you do not want logged, using the following example command syntax. You can view the CLI Reference to see what commands are available.

```

config log fortianalyzer filter
    set forward-traffic (enable | disable)
    ...
end

```

3. Enter the following commands for the second FortiAnalyzer unit:

```

config log fortianalyzer2 setting
    set status enable

```

```
set server 172.20.120.23
set max-buffer-size 1000
set buffer-max-send 2000
set address-mode static
set conn-timeout 100
set monitor-keepalive-period 120
set monitor-failure-retry-period 2000
end
```

4. Disable the features that you do not want logged, using the following example command syntax.

```
config log fortianalyzer2 filter
set event (enable | disable)
...
end
```

5. Enter the following commands for the last FortiAnalyzer unit:

```
config log fortianalyzer3 setting
set status enable
set server 172.20.120.23
set max-buffer-size 1000
set buffer-max-send 2000
set address-mode static
set conn-timeout 100
set monitor-keepalive-period 120
set monitor-failure-retry-period 2000
end
```

6. Disable the features that you do not want logged, using the following example command syntax.

```
config log fortianalyzer3 filter
set voip (enable | disable)
...
end
```

7. Test the configuration by using the procedure, [“Testing the modified log settings”](#).
8. On the other FortiGate units, configure steps 1 through 6, ensuring that logs are being sent to the FortiAnalyzer units.

Configuring logging to the FortiCloud server

The FortiCloud server can be used as a redundant backup, or your primary logging solution. The following assumes that this service has already been registered, and a subscription has been purchased for expanded space. The following is an example of how to these settings are configured for a network's log configuration. You need to have access to both the CLI and the web-based manager when configuring uploading of logs. The upload time and interval settings can be configured in the web-based interface.

To configure logging to the FortiCloud server

1. Go to **Dashboard** and click **Login** next to **FortiCloud** in the License Information widget.
2. Enter your username and password, and click **OK**. (Or register, if you have not yet done so.)
3. Logs will automatically be uploaded to FortiCloud as long as your FortiGate is linked to your FortiCloud account.
4. To configure the upload time and interval, go to **Log & Report > Log Settings**.
5. Under the **Remote Logging and Archiving** header, you can select your desired upload time.

6. With FortiCloud you can easily store and access FortiGate logs that can give you valuable insight into the health and security of your network.

Advanced logging

This section explains how to configure other log features within your existing log configuration. You may want to include other log features after initially configuring the log topology because the network has either outgrown the initial configuration, or you want to add additional features that will help your network's logging requirements.

The following topics are included in this section:

- [Log backup and restore tools](#)
- [Configuring logging to multiple Syslog servers](#)
- [Using Automatic Discovery to connect to a FortiAnalyzer unit](#)
- [Activating a FortiCloud account for logging purposes](#)
- [Viewing log storage space](#)
- [Customizing and filtering log messages](#)
- [Viewing logs from the CLI](#)
- [Configuring NAC Quarantine logging](#)
- [Logging local-in policies](#)
- [Tracking specific search phrases in reports](#)
- [Interpreting and configuring FSSO syslog log messages](#)

Log backup and restore tools

Local disk logs can now be backed up and restored to local files, using CLI commands:

```
execute log backup <filename>
execute log restore <filename>
```

Restoring logs will wipe the current log and report content off the disk.

Logs can also now be exported to a USB storage device, as LZ4 compressed files, from both CLI and GUI. When you insert a USB drive into the FortiGate's USB port, the USB menu will appear in the GUI. The menu shows the amount of storage on the USB disk, and the log file size, and you can select **Copy to USB** to copy the log data to the drive.

Configuring logging to multiple Syslog servers

A single remote Syslog server can be configured in the GUI, in **Log & Report > Log Settings**, but for a larger network, you will have to configure it in the CLI.

When configuring multiple Syslog servers (or one Syslog server), you can configure reliable delivery of log messages from the Syslog server. Configuring of reliable delivery is available only in the CLI.

If VDOMs are enabled, you can configure separate FortiAnalyzer unit or Syslog server for each VDOM.

To enable logging to multiple Syslog servers:

1. Log in to the CLI.
2. Enter the following commands:

```
config log syslogd setting
```

```
set csv {disable | enable}
set facility <facility_name>
set port <port_integer>
set reliable {disable | enable}
set server <ip_address>
set status {disable | enable}
end
```

3. Enter the following commands to configure the second Syslog server:

```
config log syslogd2 setting
set csv {disable | enable}
set facility <facility_name>
set port <port_integer>
set reliable {disable | enable}
set server <ip_address>
set status {disable | enable}
end
```

4. Enter the following commands to configure the third Syslog server:

```
config log syslogd3 setting
set csv {disable | enable}
set facility <facility_name>
set port <port_integer>
set reliable {disable | enable}
set server <ip_address>
set status {disable | enable}
end
```

5. Enter the following commands to configure the fourth Syslog server:

```
config log syslogd4 setting
set csv {disable | enable}
set facility <facility_name>
set port <port_integer>
set reliable {disable | enable}
set server <ip_address>
set status {disable | enable}
end
```

Most FortiGate features are, by default, enabled for logging. You can disable individual FortiGate features you do not want the Syslog server to record, as in this example:

```
config log syslogd filter
set local-traffic {enable | disable}
set severity {alert | critical | debug | emergency | error | information |
notification | warning}
end
```

Using Automatic Discovery to connect to a FortiAnalyzer unit

Automatic Discovery can be used if the FortiAnalyzer unit is on the same network.

To connect using automatic discovery

1. Log in to the CLI.
2. Enter the following command syntax:

```
config log fortianalyzer setting
set status enable
```

```
set server <ip_address>
set gui-display enable
set address-mode auto-discovery
end
```

If your FortiGate unit is in Transparent mode, the interface using the automatic discovery feature will not carry traffic. For more information about how to enable the interface to also carry traffic when using the automatic discovery feature, see the Fortinet Knowledge Base article, [Fortinet Discovery Protocol in Transparent mode](#).

The FortiGate unit searches within the same subnet for a response from any available FortiAnalyzer units.

Activating a FortiCloud account for logging purposes

When you subscribe to FortiCloud, you can configure to send logs to the FortiCloud server. The account activation can be done within the web-based manager, from the **License Information** widget located in **Dashboard**.

From this widget, you can easily create a new account, or log in to the existing account. From within the License Information widget, after the account is activated, you can go directly to the FortiCloud web portal, or log out of the service if you are already logged in.

To activate a FortiCloud account for logging purposes:

The following assumes that you are already at **Dashboard** and that you have located the License Information widget.

1. In the License Information widget, select **Activate** in the **FortiCloud** section.
The Registration window appears. From this window, you create the login credentials that you will use to access the account.
2. Select **Create Account** and enter then information for the login credentials.
After entering the login credentials, you are automatically logged in to your FortiCloud account.
3. Check that the account has been activated by viewing the account status from the License Information widget.

If you need more space, you can subscribe to the 200Gb FortiCloud service by selecting **Upgrade** in the **FortiCloud** section of the widget.

Viewing log storage space

The **Log & Report > Log Settings** GUI page displays two charts to visualize disk space: Disk Usage, which is a pie-chart illustrating the Free/Used space on the internal hard drive, and Historical Disk Usage, which displays the volume of disk logging activity over time. These charts may not be visible if disk logging is disabled.

The `diag sys logdisk usage` command allows you to view detailed information about how much space is currently being used for logs. This is useful when you see a high percentage, such as 92 percent for the disk's capacity. The FortiGate unit uses only 75 percent of the available disk capacity to avoid a high storage amount so when there is a high percentage, it refers to the percentage of the 75 percent that is available. For example, 92 percent of the 75 percent is available.

The following is an example of what you may see when you use `diag sys logdisk usage` command on a unit with no VDOMs configured:

```
diag sys logdisk usage
```

The following appears:

```
Total HD usage: 176MB/3011 MB
Total HD logging space: 22583MB
Total HD logging space for each vdom: 22583MB
HD logging space usage for vdom "root": 30MB/22583MB
```

Customizing and filtering log messages

When viewing log messages, you may want to customize and filter the information that you are seeing in the Log & Report menu (for example, **Log & Report > Forward Traffic**). Filtering and customizing the display provides a way to view specific log information without scrolling through pages of log messages to find the information.

Customizing log messages is the process of removing or adding columns to the log display page, allowing you to view certain desired information. The most columns represent the fields from within a log message, for example, the user column represents the user field, as well as additional information. If you want to reset the customized columns on the page back to their defaults, you need to select **Reset All Columns** within the column title right-click menu.

Filtering information is similar to customizing, however, filtering allows you to enter specific information that indicates what should appear on the page. For example, including only log messages that appeared on February 24, between the hours of 8:00 and 8:30 am.

To customize and filter log messages

The following is an example that displays all traffic log messages that originate from the source IP address 172.20.120.24, as well as displaying only the columns:

- OS Name
- OS Version
- Policy ID
- Src (Source IP)

The following assumes that you are already on the page of the log messages you want to customize and filter. In this example, the log messages that we are customizing and filtering are in **Log & Report > Forward Traffic**.

1. On the **Forward Traffic** page, right click anywhere on a column title.
2. Right click on a column title, and mouse over **Column Settings** to open the list.
3. Select each checkmarked title to uncheck it and remove them all from the displayed columns.
4. Scroll down to the list of unchecked fields and select 'OS Name', 'OS Version', 'Policy ID', and 'Src' to add checkmarks next to them.
5. Click outside the menu, and wait for the page to refresh with the new settings in place.
6. Select the funnel icon next to the word Src in the title bar of the Src column.
7. Enter the IP you want displayed (in this example, 172.20.120.24) in the text box.
8. Click **Apply**, and wait for the page to reload.

Viewing logs from the CLI

You can easily view log messages from within the CLI. In this example, we are viewing DLP log messages.

1. Log in to the CLI and then enter the following to configure the display of the DLP log messages.

```
execute log filter category 9
execute log filter start-line 1
```

```
execute log filter view-lines 20
```

The customized display of log messages in the CLI is similar to how you customize the display of log messages in the web-based manager. For example, `category 9` is the DLP log messages, and the `start-line` is the first line in the log database table for DLP log messages, and there will be 20 lines (`view-lines 20`) that will display.

2. Enter the following to view the log messages:

```
execute log display
```

The following appears below `execute log display`:

```
600 logs found
20 logs returned
```

along with the 20 DLP log messages.

Configuring NAC Quarantine logging

NAC Quarantine log messages provide information about what was banned and quarantined by a Antivirus profile. The following explains how to configure NAC Quarantine logging and enable it on a policy. This procedure assumes the Antivirus profile is already in place.

To configure NAC quarantine logging

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the policy that you want to apply the Antivirus profile to, and then select **Edit**.
3. Within the Security Profiles section, enable **Antivirus** and then select the profile from the drop-down list.
4. Select **OK**.
5. Log in to the CLI.
6. Enter the following to enable NAC Quarantine in the DLP sensor:

```
config antivirus profile
edit <profile_name>
config nac-quar log enable
end
```

Logging local-in policies

Local-in security policies are policies that control the flow of internal traffic, and can be used to broaden or restrict an administrator's access privileges. These local-in policies can also be configured to log traffic and activity that the policies control.

You can enable logging of local-in policies in the CLI, with the following commands:

```
config system global
set gui-local-in-policy enable
end
```

The Local-In Policy page will then be available in **Policy & Objects > Local In Policy**. You can configure what local-in traffic to log in the CLI, or in **Log & Report > Log Settings**, under **Local Traffic Logging**.

When deciding what local-in policy traffic you want logged, consider the following:

Special Traffic

Traffic activity	Traffic Direction	Description
FortiGuard update announcements	IN	All push announcements of updates that are coming from the FortiGuard system. For example, IPS or AV updates.
FortiGuard update requests	OUT	All updates that are checking for antivirus or IPS as well as other FortiGuard service updates.
Firewall authentication	IN	The authentication made using either the web-based manager or CLI.
Central management (a FortiGate unit being managed by a FortiManager unit)	IN	The access that a FortiManager has managing the FortiGate unit.
DNS	IN	All DNS traffic.
DHCP/DHCP Relay	IN	All DHCP and/or DHCP Relay traffic.
HA (heart beat sync policy)	IN/OUT	For high-end platforms with a backplane heart beat port.
HA (Session sync policy)	IN/OUT	This will get information from the CMDB and updated by session sync daemon.
CAPWAP	IN	This activity is logged only when a HAVE_CAPWAP is defined.
Radius	IN	This is recorded only within FortiCarrier.
NETBIOS forward	IN	Any interface that NETBIOS forward is enabled on.
RIP	IN	
OSPF	IN	
VRRP	IN	
BFD	IN	
IGMP	IN	This is recorded only when PIM is enabled.
PIM	IN	This is recorded only when PIM is enabled.

Traffic activity	Traffic Direction	Description
BGP	IN	This is recorded only when config bgp and bgp neighbor is enabled in the CLI.
WCCP policy	IN	Any interface that WCCP is enabled; however, if in Cache mode, this is not recorded because it is not available.
WAN Opt/ Web Cache	IN	Any interface where WAN Opt is enabled.
WANOpt Tunnel	IN	This is recorded when HAVE_WANOPT is defined.
SSL-VPN	IN	Any interface from a zone where the action in the policy is SSL VPN.
IPSEC	IN	
L2TP	IN	
PPTP	IN	
VPD	IN	This is recorded only when FortiClient is enabled.
Web cache db test facility	IN	This is recorded only when WA_CS_REMOTE_TEST is defined.
GDBserver	IN	This is recorded only when debug is enabled.

Tracking specific search phrases in reports

It is possible to use the Web Filter to track specific search keywords and phrases and record the results for display in the report.

You should verify that the web filter profile you are using indicates what search phrases you want to track and monitor, so that the report includes this information.

1. Log in to the CLI and enter show webfilter profile default.

This provides details about the webfilter profile being used by the security policy. In this example, the details (shown in the following in bold) indicate that safe search is enabled, but not specified or being logged.

```
show webfilter profile default
config webfilter profile
edit "default"
    set comment "default web filtering"
    set inspection-mode flow-based
    set options https-scan
    set post-action comfort
    config web
        set safe-search url
    end
    config ftgd-wf
        config filters
            edit 1
```

```

        set action block
        set category 2
    next
    edit 2
        set action block
        set category 7
    next
    edit 3
        set action block
        set category 8

```

2. Enter the following command syntax so that logging and the keyword for the safe search will be included in logging.

```

config webfilter profile
  edit default
    config web
      set log-search enable
      set keyword-match "fortinet" "easter" "easter bunny"
    end
  end
end

```

3. To test that the keyword search is working, go to a web browser and begin searching for the words that were included in the webfilter profile, such as easter.

You can tell that the test works by going to **Log & Report > Forward Traffic** and viewing the log messages.

Interpreting and configuring FSSO syslog log messages

There are two syslog message formats: default and verbose. Verbose must be manually enabled as described below, but provides more general information.

Default syslog message format

The default FSSO syslog message format has no header, and is based on the specifications of [RFC 3164](#). Messages only have two values, `PRI` (Priority) and `MSG` (Message), in the format of `<PRI>MSG`.

The content of `PRI` is as described in RFC 3164, but with specific parameters: the Facility value is always 1 (USER), unless 'Log logons in separate log' is enabled in the FSSO Collector Agent settings. In that case, those logon messages will have a Facility value of 4 or 10 (AUTH). The Severity value always matches the internal severity value of the log. `PRI` is enclosed in `<>` with no space following before `MSG`.

Verbose syslog message format

Verbose is a secondary message format that provides more information, including timestamp (with timezone).

In verbose mode, the log message follows the specifications of [RFC 5424](#):

```

<PRI>VERSION TIMESTAMP HOSTNAME APP-NAME PROCID MSGID STRUCTURED-DATA/SD-ID
MSG

```

`PRI` is formatted as described above in the default format.

Verbose FSSO syslog messages do not contain any data for `MSGID`, or `STRUCTURED-DATA`, so both of those two messages are recorded as a single hyphen character `"-"`.

`APP-NAME` always appears as `"collectoragent"`.

The other values are formatted as described in RFC 5424.

Enabling verbose syslog message mode

In order to enable the verbose syslog message mode, you must modify the registry on the PC that is hosting the FSSO Collector Agent.

In 64-bit Windows, locate the following registry entry:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\Fortinet\FSAE\collectoragent
```

In 32-bit Windows, locate the following registry entry:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\collectoragent
```

Under this registry path, create a new DWORD (32bit) Value named `syslog_using_rfc`, and set its value to 1.

Troubleshooting and logging

This section explains how to troubleshoot logging configuration issues, as well as connection issues, that you may have with your FortiGate unit and a log device. This section also contains information about how to use log messages when troubleshooting issues that are about other FortiGate features, such as VPN tunnel errors.

Using log messages to help in troubleshooting issues

Log messages can help when troubleshooting issues that occur, since they can provide details about what is occurring. The uses and methods for involving logging in troubleshooting vary depending on the problem. The following are examples of how log messages can assist when troubleshooting networking issues.

Using IPS packet logging in diagnostics

This type of logging should only be enabled when you need to know about specific diagnostic information, for example, when you suspect a signature is triggered by a false positive. These log messages can help troubleshoot individual problems with misidentified or missing packets and network intrusions involving malicious packets.

To configure IPS packet logging

1. Go to **Security Profiles > Intrusion Protection**.
2. Select the IPS sensor that you want to enable IPS packet logging on, and then select **Edit**.
3. In the filter options, enable **Packet Logging**.
4. Select **OK**.

If you want to configure the packet quota, number of packets that are recorded before alerts and after attacks, use the following procedure.

To configure additional settings for IPS packet logging

1. Log in to the CLI.
2. Enter the following to start configuring additional settings:

```
config ips settings
    set ips-packet-quota <integer>
    set packet-log-history <integer>
    set packet-log-post-attack <integer>
end
```

Using HA log messages to determine system status

When the FortiGate unit is in HA mode, you may see the following log message content within the event log:

```
type=event subtype=ha level=critical msg= "HA slave heartbeat interface internal lost
neighbor information"
```

OR

```
type=event subtype=ha level=critical msg= "Virtual cluster 1 of group 0 detected new
joined HA member"
```

OR

```
type=event subtype=ha level=critical msg= "HA master heartbeat interface internal get peer information"
```

The log messages occur within a given time, and indicate that the units within the cluster are not aware of each other anymore. These log messages provide the information you need to fix the problem.

Connection issues between FortiGate unit and logging devices

If external logging devices are not recording the log information properly or at all, the problem will likely be due to one of two situations: no data is being received because the log device cannot be reached, or no data is being sent because the FortiGate unit is no longer logging properly.

Unable to connect to a supported log device

After configuring logging to a supported log device, and testing the connection, you may find you cannot connect. To determine whether this is the problem:

1. Verify that the information you entered is correct; it could be a simple mistake within the IP address or you may have not selected **Apply** on the Log Settings page after changing them, which would prevent them from taking effect.
2. Use `execute ping` to see if you can ping to the log device.
3. If you are unable to ping to the log device, check to see if the log device itself working and that it is on the network and assigned an appropriate address.

FortiGate unit has stopped logging

If the FortiGate unit stopped logging to a device, test the connection between both the FortiGate unit and device using the `execute ping` command. The log device may have been turned off, is upgrading to a new firmware version, or just not working properly.

The FortiGate unit may also have a corrupted log database. When you log into the web-based manager and you see an SQL database error message, it is because the SQL database has become corrupted. View "SQL database errors" in the next section before taking any further actions, to avoid losing your current logs.

Log database issues

If attempting to troubleshoot issues with the SQL log database, use the following to help guide you to solving issues that occur.

SQL statement syntax errors

There may be errors or inconsistencies in the SQL used to maintain the database. Here are some example error messages and possible causes:

```
You have an error in your SQL syntax (remote/MySQL)
```

or

```
ERROR: syntax error at or near... (local/PostgreSQL)
```

- Verify that the SQL keywords are spelled correctly, and that the query is well-formed.
- Table and column names are demarked by grave accent (`) characters. Single (') and double (") quotation marks will cause an error.

```
No data is covered.
```

- The query is correctly formed, but no data has been logged for the log type. Verify that you have configured the FortiGate unit to save that log type. On the Log Settings page, make sure that the log type is checked.

Connection problems

If well-formed SQL queries do not produce results, and logging is turned on for the log type, there may be a database configuration problem with the remote database.

Ensure that:

- MySQL is running and using the default port 3306.
- You have created an empty database and a user who has read/write permissions for the database.
- Here is an example of creating a new MySQL database named fazlogs, and adding a user for the database:

1. `#Mysql -u root -p`
2. `mysql> Create database fazlogs;`
3. `mysql> Grant all privileges on fazlogs.* to 'fazlogger'@'*' identified by 'fazpassword';`
4. `mysql> Grant all privileges on fazlogs.* to 'fazlogger'@'localhost' identified by 'fazpassword';`

SQL database errors

If the database seems inaccessible, you may encounter the following error message after upgrading or downgrading the FortiGate unit's firmware image.

Example of an SQL database error message

The error message indicates that the SQL database is corrupted and cannot be updated with the SQL schemas any more. When you see this error message, you can do one of the following:

- select **Cancel** and back up all log files; then select **Rebuild** to blank and rebuild the database.
- select **Rebuild** immediately, which will blank the database and previous logs will be lost.

Until the database is rebuilt, no information will be logged by the FortiGate unit regardless of the log settings that are configured on the unit. When you select **Rebuild**, all logs are lost because the SQL database is erased and then rebuilt again. Logging resumes automatically according to your settings after the SQL database is rebuilt.

To view the status of the database, use the `diagnose debug sqlldb-error status` command in the CLI. This command will inform you whether the database has errors present.

If you want to view the database's errors, use the `diagnose debug sqlldb-error read` command in the CLI. This command indicates exactly what errors occurred, and what tables contain those errors.

Log files are backed up using the `execute backup {disk | memory} {alllogs | logs}` command in the CLI. You must use the text variable when backing up log files because the text variable allows you to view the log files outside the FortiGate unit. When you back up log files, you are really just copying the log files from the database to a specified location, such as a TFTP server.

Logging daemon (Miglogd)

The number of logging daemon child processes has been made available for editing. A higher number can affect performance, and a lower number can affect log processing time, although no logs will be dropped or lost if the number is decreased.

If you are suffering from performance issues, you can alter the number of logging daemon child processes, from 0 to 15, using the following syntax. The default is 8.

```
config system global
    set miglogd-children <integer>
end
```

Chapter 15 - Managing Devices

[What's new in FortiOS 6.0](#)

[Managing “bring your own device”](#)

This handbook chapter contains the following sections:

[Managing “bring your own device”](#) describes device monitoring, devices, device groups, and device policies. The administrator can monitor all types of devices and control their access to network resources.

What's new in FortiOS 6.0

The following list contains new device management features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- ["Device organization, device categories, and device types" on page 1894](#)

Managing “bring your own device”

FortiOS can control network access for different types of personal mobile devices that your employees bring onto your premises. You can:

- identify and monitor the types of devices connecting to your networks, wireless or wired
- use MAC address based access control to allow or deny individual devices
- create security policies that specify device types
- enforce endpoint control on devices that can run FortiClient Endpoint Control software

This chapter contains the following sections:

Device monitoring

The FortiGate unit can monitor your networks and gather information about the devices operating on those networks. Collected information includes:

- MAC address
- IP address
- operating system
- hostname
- user name
- how long ago the device was detected and on which FortiGate interface

You can go to **User & Device > Device Inventory** to view this information. Mouse-over the **Device** column for more details.

 Edit	 Delete	 Refresh	 Search	By Type	By Interface	Alphabetically	Total Devices Tracked: 47
 Status	 Device	 OS	 User	 IP Address	 Interface		
 Online	 00:12:7f:4d:4d:97				 wan1		
 Online	 00:14:a9:52:23:82				 wan1		
 Online	 amoffitt-pc	Windows / 7, 8 (x86)		172.20.120.51	 wan1		
 Online	 DAHLIA			172.20.121.150	 wan1		
 Offline	 00:09:0f:09:de:12			172.20.121.2	 wan1		
 Offline	 00:0c:29:07:ae:75				 wan1		

Depending on the information available, the Device column lists the Alias or the MAC address of the device. For ease in identifying devices, Fortinet recommends that you assign each device an Alias.

Device monitoring is enabled separately on each interface. Device detection is intended for devices directly connected to your LAN ports. If enabled on a WAN port, device detection may be unable to determine the operating system on some devices. Hosts whose device type cannot be determined passively can be found by enabling active scanning on the interface.

You can also manually add devices. This enables you to ensure that a device with multiple interfaces is displayed as a single device.

To configure device monitoring

1. Go to **Network > Interfaces**.
2. Edit the interface that you want to monitor devices on.
3. In **Networked Devices**, turn on **Device Detection** and optionally turn on **Active Scanning**.
4. Select **OK**.
5. Repeat steps 2 through 4 for each interface that will monitor devices.

To assign an alias to a detected device or change device information

1. Go to **User & Device > Device Inventory** and edit the device entry.
2. Enter an **Alias** such as the user's name to identify the device.
3. Change other information as needed.
4. Select **OK**.

To add a device manually

1. Go to **User & Device > Custom Devices & Groups**.
2. Select **Create New > Device**.
3. Enter the following information:
 - Alias (required)
 - MAC address
 - Additional MACs (other interfaces of this device)
 - Device Type
 - Optionally, add the device to **Custom Groups**.
 - Optionally, enter **Comments**.
3. Select **OK**.

Custom avatars for custom devices

You can upload an avatar for a custom device. The avatar is then displayed in the GUI wherever the device is listed, such as FortiView, log viewer, or policy configuration. To upload an avatar image, click **Upload Image** on the New Device or Edit Device page of **User & Device > Custom Devices & Groups**. The image can be in any format your browser supports and will be automatically sized to 36 x 36 pixels for use in the FortiGate GUI.

Device offline timeout

A device is considered offline if it has not sent any packets during the timeout period. The timeout can be set to any value from 30 to 31 536 000 seconds (365 days). The default value is 300 seconds (5 minutes). The timer is configurable in the CLI:

```
config system global
    set device-idle-timeout 300
end
```

Device organization, device categories, and device types

A second level of organization shows device category (except for device types not listed below). The categories, along with the devices that belong to those categories, include:

Category	Devices
Android	Android Phone, Android Tablet
BlackBerry	BlackBerry Phone, BlackBerry Playbook
Fortinet	Fortinet Device, FortiCam, FortiFone
iOS	iPad, iPhone
Windows	Windows PC, Windows Phone, Windows Tablet

Syntax

```
config user device
  edit <category>
    set category [none | android-device | blackberry-device | fortinet-device | ios-
device | windows-device]
  next
end
```

Device groups

You can specify multiple device types in a security policy. As an alternative, you can add multiple device types to a custom device group and include the group in the policy. This enables you to create a different policy for devices that you know than for devices in general.

To create a custom device group and add devices to it

1. Go to **User & Device > Custom Devices & Groups**.
The list of device groups is displayed.
2. Select **Create New > Device Group**.
3. Enter a **Name** for the new device group.
4. Click in the **Members** field and click a device type to add. Repeat to add other devices.
5. Select **OK**.

Controlling access with a MAC Address Access Control List

A MAC Address Access Control List (ACL) allows or blocks access on a network interface that includes a DHCP server. If the interface does not use DHCP, or if you want to limit network access to a larger group such as employee devices, it is better to create a device group and specify that group in your security policies.

A MAC Address ACL functions as either

- a list of devices to block, allowing all other devices

or

- a list of devices to allow, blocking all other devices

Allowed devices are assigned an IP address. The Assign IP action assigns the device an IP address from the DHCP range. In a list of allowed devices, you can also use the Reserve IP action to always provide a specific IP address to the device.

The **Unknown MAC Address** entry applies to "other" unknown, unlisted devices. Its action must be opposite to that of the other entries. In an allow list, it must block. In a block list, it must allow.

To create a MAC Address ACL to allow only specific devices

1. Go to the SSID or network interface configuration.
2. In the **DHCP Server** section, expand **Advanced**.
DHCP Server must be enabled.
3. In **MAC Reservation + Access Control**, select **Create New** and enter an allowed device's **MAC Address**.
4. In the **IP or Action** column, select one of:
 - Assign IP — device is assigned an IP address from the DHCP server address range.
 - Reserve IP — device is assigned the IP address that you specify.
5. Repeat Steps ["Controlling access with a MAC Address Access Control List" on page 1894](#) and ["Controlling access with a MAC Address Access Control List" on page 1894](#) for each additional MAC address entry.
6. Set the **Unknown MAC Address** entry **IP or Action** to **Block**.
Devices not in the list will be blocked.
7. Select **OK**.

To create a MAC Address ACL to block specific devices

1. Go to the SSID or network interface configuration.
2. In the **DHCP Server** section, expand **Advanced**.
DHCP Server must be enabled.
3. In **MAC Reservation + Access Control**, select **Create New** and enter the **MAC Address** of a device that must be blocked.
4. In the **IP or Action** column, select **Block**.
5. Repeat Steps ["Controlling access with a MAC Address Access Control List" on page 1894](#) and ["Controlling access with a MAC Address Access Control List" on page 1894](#) for each device that must be blocked.
6. Set the **Unknown MAC Address** entry **IP or Action** to **Assign IP**.
Devices not in the list will be assigned IP addresses.
7. Select **OK**.

MAC Authentication Bypass (MAB)

MAC Authentication Bypass allows devices without 802.1X capability (printers and IP phones for example) to bypass authentication and be allowed network access based on their MAC address. This feature requires RADIUS-based 802.1X authentication in which the RADIUS server contains a database of authorized MAC addresses.

MAC Authentication Bypass is configurable only in the CLI and only on interfaces configured for 802.1X authentication. For example:

```
config system interface
edit "lan"
set ip 10.0.0.200 255.255.255.0
```

```
        set vlanforward enable
        set security-mode 802.1X
        set security-mac-auth-bypass enable
        set security-groups "Radius-group"
    end
end
```

MAC Authentication Bypass is also available on WiFi SSIDs, regardless of authentication type. It is configurable only in the CLI. You need to enable the `radius-mac-auth` feature and specify the RADIUS server that will be used. For example:

```
config wireless-controller vap
    edit "office-ssid"
        set security wpa2-only-enterprise
        set auth usergroup
        set usergroup "staff"
        set radius-mac-auth enable
        set radius-mac-auth-server "ourRadius"
    end
end
```

Security policies for devices

Security policies enable you to implement policies according to device type. For example:

- Gaming consoles cannot connect to the company network or the Internet.
- Personal tablet and phone devices can connect to the Internet but not to company servers.
- Company-issued laptop computers can connect to the Internet and company servers. Web filtering and antivirus are applied.
- Employee laptop computers can connect to the Internet, but web filtering is applied. They can also connect to company networks, but only if FortiClient Endpoint Security is installed to protect against viruses.

The following images show these policies implemented for WiFi to the company network and to the Internet.

Device policies for company laptop access to the company network

New Policy	
Name	Laptop LAN Access
Incoming Interface	 internal (lan) 
Outgoing Interface	 lan 
Source	 1st floor LAN   employee laptop 
Destination Address	 all 
Schedule	always 
Services	 ALL 
Action	ACCEPT DENY

Device policies for WiFi access to the Internet

New Policy	
Name	WiFi access to Internet
Incoming Interface	 example-staff (example-wifi) 
Outgoing Interface	 wan1 
Source	 all   Android Phone   Android Tablet   BlackBerry Phone   BlackBerry PlayBook   iPad   iPhone 
Destination Address	 all 
Schedule	always 
Services	 ALL 
Action	ACCEPT DENY

The next section explains device policy creation in detail.

Creating device policies

Device-based security policies are similar to policies based on user identity:

- The policy enables traffic to flow from one network interface to another.
- NAT can be enabled.
- UTM protection can be applied.

To create a device policy

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Choose **Incoming Interface**, **Outgoing Interface** and **Source** as you would for any security policy.
3. In **Source**, select an address and the device types that can use this policy.
You can select multiple devices or device groups.
4. Turn on **NAT** if appropriate.
5. Configure **Security Profiles** as you would for any security policy.
6. Select **OK**.

Adding endpoint protection

Optionally, you can require that users' devices connecting to a particular network interface have FortiClient Endpoint Security software installed. Devices without an up-to-date installation of FortiClient software are restricted to a captive portal from which the user can download a FortiClient installer. For information about creating FortiClient profiles, see "Endpoint Protection".

To add endpoint protection to a security policy

1. Go to **Network > Interfaces** and edit the interface.
2. In **Admission Control** turn on **Allow FortiClient Connections** and **FortiClient Enforcement**.
3. Optionally, select sources (addresses and device types) to exempt from FortiClient enforcement.
4. Optionally, select destination addresses and services to exempt from FortiClient enforcement.
5. Select **OK**.

FortiOS pushes a FortiClient profile out to the FortiClient software, configuring network protection such as antivirus, application control, and web category filtering. To create these profiles, go to **Security Profiles > FortiClient Profiles**.

FortiClient endpoint licence updates

FortiClient endpoint licenses for FortiOS 5.6.0 can be purchased in multiples of 100. There is a maximum client limit based on the FortiGate's model. FortiCare enforces the maximum limits when the customer is applying the license to a model.

If you are using the ten free licenses for FortiClient, support is provided on the Fortinet Forum (forum.fortinet.com). Phone support is only available for paid licenses.

Model(s)	Maximum Client Limit
VM00	200
FGT/FWF 30 to 90 series	200
FGT 100 to 400 series	600
FGT 500 to 900 series, VM01, VM02	2,000
FGT 1000 to 2900 series	20,000
FGT 3000 to 3600 series, VM04	50,000
FGT 3700D and above, VM08 and above	100,000

Older FortiClient SKUs will still be valid and can be applied to FortiOS 5.4 and 5.6.

Chapter 16 - FortiSwitch Devices Managed by FortiOS

6.0.1

Introduction

NOTE: FortiLink is not supported in transparent mode.

The maximum number of supported FortiSwitch units depends on the FortiGate model:

FortiGate Model Range	Number of FortiSwitch Units Supported
Up to FortiGate-98 and FortiGate-VM01	8
FortiGate-100 to 280 and FortiGate-VM02	24
FortiGate-300 to 5xx	48
FortiGate-600 to 900 and FortiGate-VM04	64
FortiGate-1000 and up	128
FortiGate-3xxx and up and FortiGate-VM08 and up	300

Supported models

The following table shows the FortiSwitch models that support FortiLink mode when paired with the corresponding FortiGate models and the listed minimum software releases. For example, the FGT-500E model with FortiOS 5.6.3 and later supports all FortiSwitch D-series and E-series models running FortiSwitchOS 3.6.0 and later.

Each row includes support for earlier FortiGate models. For example, the FGT-500E row includes support by the FortiGate models in the rows above it.

FortiGate and FortiWiFi Models	Earliest FortiOS	FortiSwitch Models
FGT-90D	5.2.2	FS-224D-POE

FortiGate and FortiWiFi Models	Earliest FortiOS	FortiSwitch Models
FGT-60D FGT-100D, 140D, 140D-POE, 140D-T1 FGT-200D, 240D, 280D, 280D-POE FGT-600C FGT-800C FGT-1000C, 1200D, 1500D FGT-3700D, FGT-3700DX	5.2.3	FSR-112D-POE FS-108D-POE FS-124D (POE) FS-224D-POE and FPOE
	5.4.0	All FortiSwitch D-series models. FortiSwitchOS 3.3.x or 3.4.0 is recommended.
FGT and FWF-30D, 30D-POE, 30E FGT and FWF-50E, 51E FGR-60D FGT-70D, 70D-POE FGT-80D FGR-90D FGT and FWF-92D FGT-94D-POE, 98D-POE FGT-300D FGT-400D FGT-500D FGT-600D FGT-900D FGT-1000D FGT-3000D, 3100D, 3200D, 3240C, 3600C, 3810D, 3815D FGT_VM, VM64, VM64-AWS, VM64-AWSONDEMAND, VM64-HV, VM64-KVM, VM-VMX, VM64-XEN	5.4.1	All FortiSwitch D-series models. FortiSwitchOS 3.4.2 or later is required for all managed switches.
FGT and FWF- 60E, 61E FGT-100E, 101E	5.4.2	All FortiSwitch D-series models. FortiSwitchOS 3.4.2 or later is required for all managed switches.
FGT-80E, 80E-POE, 81E, 81E-POE FGT-100EF	5.4.3	All FortiSwitch D-series models. FortiSwitchOS 3.4.2 or later is required for all managed switches.
FGT-90E, 91E FGT-200E, 201E FGT-2000E, 2500E	5.6.0	All FortiSwitch D-series models. FortiSwitchOS 3.5.4 or later is required for all managed switches.

FortiGate and FortiWiFi Models	Earliest FortiOS	FortiSwitch Models
FGT-500E	5.6.3	<p>All FortiSwitch D-series and E-series models.</p> <p>FortiSwitchOS 3.6.0 or later is required for all managed switches.</p>

Support of FortiLink features

The following table lists the FortiSwitch models supported by FortiLink features.

FortiLink Features	FortiSwitch Models
Centralized VLAN Configuration	D-series, E-series
Switch POE Control	D-series, E-series
Link Aggregation Configuration	D-series, E-series
Spanning Tree Protocol (STP)	D-series, E-series
LLDP/MED	D-series, E-series
IGMP Snooping	Not supported on 112D-POE, 1xxE-Series
802.1x Authentication (Port-based, MAC-based, MAB)	D-series, E-series
Syslog Collection	D-series, E-series
DHCP Snooping	Not supported on 1xxE-Series
Device Detection	D-series, E-series
Support FortiLink FortiGate in HA Cluster	D-series, E-series
LAG support for FortiLink Connection	D-series, E-series
Active-Active Split MLAG from FortiGate to FortiSwitch units for Advanced Redundancy	Not supported on FS-1xx Series
sFlow	Not supported on 1xxE-Series
Dynamic ARP Inspection (DAI)	Not supported on 1xxE-Series
Port Mirroring	D-series, E-series
RADIUS Accounting Support	Not supported on 1xxE-Series

FortiLink Features	FortiSwitch Models
Centralized Configuration	D-series, E-series
Access VLAN	Not supported on 1xxE-Series, 112D-POE
STP BPDU Guard, Root Guard, Edge Port	D-series, E-series
Loop Guard	D-series, E-series
Switch admin Password	D-series, E-series
Storm Control	D-series, E-series
802.1x-Authenticated Dynamic VLAN Assignment	D-series, E-series
Host Quarantine on Switch Port	Not supported on 1xxE Series, 112D-POE
QoS	Not supported on 1xxE-Series, 112D-POE
Centralized Firmware Management	D-series, E-series

Before you begin

Before you configure the managed FortiSwitch unit, the following assumptions have been made in the writing of this manual:

- You have completed the initial configuration of the FortiSwitch unit, as outlined in the QuickStart Guide for your FortiSwitch model, and you have administrative access to the FortiSwitch web-based manager and CLI.
- You have installed a FortiGate unit on your network and have administrative access to the FortiGate web-based manager and CLI.

How this guide is organized

This guide contains the following sections:

- [What's new in FortiOS 6.0.1](#) describes the new features for this release.
- [Connecting FortiLink ports](#) describes how to connect FortiSwitch ports to FortiGate ports.
- [FortiLink configuration using the FortiGate GUI](#) describes how to use the FortiGate GUI for FortiLink configuration.
- [FortiLink configuration using the FortiGate CLI](#) describes how to use the FortiGate CLI for FortiLink configuration.
- [Network topologies for managed FortiSwitch units](#) describes the configuration for various network topologies.
- [Optional setup tasks](#) describes other setup tasks that are optional.
- [FortiSwitch features configuration](#) describes how to configure managed FortiSwitch features, including VLANs.
- [FortiSwitch port features](#) describe how to configure ports and PoE from the FortiGate unit.
- [FortiSwitch port security policy](#) describes how to set up FortiSwitch security policies.
- [Additional capabilities](#) describes more FortiSwitch features.
- [Troubleshooting](#) describes techniques for troubleshooting common problems.

What's new in FortiOS 6.0.1

The following list contains new managed FortiSwitch features added in FortiOS 6.0.1. Click on a link to navigate to that section for further information.

- ["Logging violations of the MAC address learning limit \(480808\)" on page 1904](#)
- ["Testing 802.1x authentication with monitor mode \(480807\)" on page 1905](#)
- ["Checking FortiSwitch connections \(453491\)" on page 1905](#)
- ["CLI changes for quarantining MAC addresses \(442831\)" on page 1906](#)
- ["CLI changes for releasing MAC addresses from quarantine \(442831\)" on page 1907](#)

What's new in FortiOS 6.0

The following list contains new managed FortiSwitch features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- ["Limiting the number of learned MAC addresses on a FortiSwitch interface \(445087\)" on page 1907](#)
- ["Sharing FortiSwitch ports between VDOMs \(391878\)" on page 1908](#)
- ["sFlow support \(450507\)" on page 1910](#)
- ["Restricting the type of frames allowed through IEEE 802.1Q ports \(448505\)" on page 1911](#)
- ["Dynamic ARP inspection \(DAI\) support \(462511\)" on page 1912](#)
- ["FortiSwitch port mirroring support \(457122\)" on page 1912](#)
- ["Quarantining MAC addresses \(459525\)" on page 1913](#)
- ["Banning IP addresses \(459525\)" on page 1913](#)
- ["Synchronizing the FortiGate unit with the managed FortiSwitch units \(454664\)" on page 1914](#)
- ["Enabling the use of HTTPS to download firmware to managed FortiSwitch units \(454664\)" on page 1914](#)
- ["RADIUS accounting support \(451023\)" on page 1914](#)
- ["FortiLink mode supported over a layer-3 network \(457103\)" on page 1915](#)
- ["Limiting the number of parallel process for FortiSwitch configuration \(457103\)" on page 1916](#)
- ["CLI changes for FortiLink mode \(447349, 473773\)" on page 1917](#)
- ["Upgrade the firmware on multiple FortiSwitch units at the same time using the GUI \(462553\)" on page 1917](#)
- ["Network-assisted device detection \(377467\)" on page 1918](#)

FortiOS 6.0.1

These features first appeared in FortiOS 6.0.1.

Logging violations of the MAC address learning limit (480808)

If you set a maximum number of MAC addresses learned for an interface or VLAN, the managed FortiSwitch unit drops all traffic for additional MAC addresses after the learning limit is reached.

You can now change how long learned MAC addresses are stored. By default, each learned MAC address is aged out after 300 seconds. The value ranges from 0 to 1,500 minutes. To disable MAC address aging, set the value to zero.

If you want to see the first MAC address that exceeded the learning limit for an interface or VLAN, you can enable the learning-limit violation log for a managed FortiSwitch unit. Only one violation is recorded per interface or VLAN.

By default, logging is disabled. The most recent violation that occurred on each interface or VLAN is recorded in the system log. After that, no more violations are logged until the log is reset for the triggered interface or VLAN. Only the most recent 128 violations are displayed in the console.

Use the following commands to control the learning-limit violation log and to control how long learned MAC addresses are save:

```
config switch-controller global
    set mac-violation-timer <0-1500>
    set log-mac-limit-violations {enable | disable}
end
```

To view the content of the learning-limit violation log for a managed FortiSwitch unit, use one of the following commands:

- `diagnose switch-controller dump mac-limit-violations all <FortiSwitch_serial_number>`
- `diagnose switch-controller dump mac-limit-violations interface <FortiSwitch_serial_number> <port_name>`
- `diagnose switch-controller dump mac-limit-violations vlan <FortiSwitch_serial_number> <VLAN_ID>`

To reset the learning-limit violation log for a managed FortiSwitch unit, use one of the following commands:

- `execute switch-controller mac-limit-violation reset all <FortiSwitch_serial_number>`
- `execute switch-controller mac-limit-violation reset vlan <FortiSwitch_serial_number> <VLAN_ID>`
- `execute switch-controller mac-limit-violation reset interface <FortiSwitch_serial_number> <port_name>`

Testing 802.1x authentication with monitor mode (480807)

Use the monitor mode to test your system configuration for 802.1x authentication. You can use monitor mode to test port-based authentication, MAC-based authentication, EAP pass-through mode, and MAC authentication bypass. Monitor mode is disabled by default. After you enable monitor mode, the network traffic will continue to flow, even if the users fail authentication.

To enable or disable monitor mode, use the following commands:

```
config switch-controller security-policy 802-1X
    edit "<policy_name>"
        set open-auth {enable | disable}
    next
end
```

Checking FortiSwitch connections (453491)

A new CLI command provides detailed diagnostic information on the managed FortiSwitch connections:

```
execute switch-controller diagnose-connection <FortiSwitch_serial_number>
```

If the FortiSwitch serial number is omitted, only the FortiLink configuration is checked.

CLI changes for quarantining MAC addresses (442831)

The CLI commands to create a permanent quarantine of specific MAC addresses have changed to allow multiple MAC addresses to be quarantined in the same session.

```
config user quarantine
  set quarantine enable
  config targets
    edit <quarantine_entry_name>
      set description <string>
      config macs
        edit <MAC_address_1>
        next
        edit <MAC_address_2>
        next
        edit <MAC_address_3>
        next
      end
    end
  end
```

Option	Description
quarantine_entry_name	A name for this quarantine entry.
string	Optional. A description of the MAC addresses being quarantined.
MAC_address_1, MAC_address_2, MAC_address_3	A layer-2 MAC address in the following format: 12:34:56:aa:bb:cc

For example:

```
config user quarantine
  set quarantine enable
  config targets
    edit quarantine1
      config macs
        set description "infected by virus"
        edit 00:00:00:aa:bb:cc
        next
        edit 00:11:22:33:44:55
        next
        edit 00:01:02:03:04:05
        next
      end
    end
  end
```

CLI changes for releasing MAC addresses from quarantine (442831)

To release MAC addresses from quarantine, you can delete a single MAC address or delete a quarantine entry, which will delete all of the MAC addresses listed in the entry.

To delete a single quarantined MAC address:

```
config user quarantine
  config targets
    edit <quarantine_entry_name>
      config macs
        delete <MAC_address_1>
      end
    end
  end
end
```

To delete all MAC addresses in a quarantine entry:

```
config user quarantine
  config targets
    delete <quarantine_entry_name>
  end
end
```

FortiOS 6.0

These features first appeared in FortiOS 6.0.

Limiting the number of learned MAC addresses on a FortiSwitch interface (445087)

You can limit the number of MAC addresses learned on a FortiSwitch interface (port or VLAN). The limit ranges from 1 to 128. If the limit is set to the default value zero, there is no learning limit.

NOTE: Static MAC addresses are not counted in the limit. The limit refers only to learned MAC addresses.

Use the following CLI commands to limit MAC address learning on a VLAN:

```
config switch vlan
  edit <integer>
    set switch-controller-learning-limit <limit>
  end
end
```

For example:

```
config switch vlan
  edit 100
    set switch-controller-learning-limit 20
  end
end
```

Use the following CLI commands to limit MAC address learning on a port:

```
config switch-controller managed-switch
  edit <FortiSwitch_Serial_Number>
    config ports
      edit <port>
        set learning-limit <limit>
      end
    end
  end
end
```

```

        next
    end
end
end

```

For example:

```

config switch-controller managed-switch
  edit S524DF4K15000024
    config ports
      edit port3
        set learning-limit 50
      next
    end
  end
end

```

Sharing FortiSwitch ports between VDOMs (391878)

Virtual domains (VDOMs) are a method of dividing a FortiGate unit into two or more virtual units that function as multiple independent units. VDOMs provide separate security domains that allow separate zones, user authentication, security policies, routing, and VPN configurations.

FortiSwitch ports can now be shared between VDOMs.

NOTE: You cannot use the quarantine feature while sharing FortiSwitch ports between VDOMs.

To share FortiSwitch ports between VDOMs:

1. Create one or more VDOMs.
2. Assign VLANs to each VDOM as required.
3. From these VLANs, select one VLAN to be the default VLAN for the ports in the virtual switch:

```

config switch-controller global
  set default-virtual-switch-vlan <VLAN>

```

NOTE: You must execute these commands from the VDOM that the default VLAN belongs to.

When you add a new port to the VDOM, the new port will be automatically assigned to the default VLAN. You can reassign the ports to other VLANs later.

4. Create a virtual port pool (VPP) to contain the ports to be shared:

```

config switch-controller virtual-port-pool
  edit <VPP_name>
    description <string>
  next
end

```

NOTE: You must execute these commands from the VDOM that the default VLAN belongs to.

For example:

```

config switch-controller virtual-port-pool
  edit "pool3"
    description "pool for port3"

```

```

    next
end

```

5. Share a FortiSwitch port from the VDOM that the FortiSwitch belongs to with another VDOM or export the FortiSwitch port to a VPP where it can be used by any VDOM:

```

config switch-controller managed-switch
  edit <switch.id>
    config ports
      edit <port_name>
        set {export-to-pool <VPP_name> | export-to <VDOM_name>}
        set export-tags <string1,string2,string3,...>
      next
    end
  next
end

```

NOTE: You must execute these commands from the VDOM that the default VLAN belongs to.

For example, if you want to export a port to the VPP named `pool3`:

```

config switch-controller managed-switch
  edit "S524DF4K15000024"
    config ports
      edit port3
        set export-to-pool "pool3"
        set export-tags "Pool 3"
      next
    end
  next
end

```

For example, if you want to export a port to the VDOM named `vdom3`:

```

config switch-controller managed-switch
  edit "S524DF4K15000024"
    config ports
      edit port3
        set export-to "vdom3"
        set export-tags "VDOM 3"
      next
    end
  next
end

```

6. Request a port in a VPP:

```

execute switch-controller virtual-port-pool request <FortiSwitch_device_ID> <port_name>

```

NOTE: You must execute this command from the VDOM that is requesting the port.

For example:

```

execute switch-controller virtual-port-pool request S524DF4K15000024h port3

```

7. Return a port to a VPP:

```

execute switch-controller virtual-port-pool return <FortiSwitch_device_ID> <port_name>

```

NOTE: You must execute this command from the VDOM that owns the port.

For example:

```
execute switch-controller virtual-port-pool return S524DF4K15000024h port3
```

You can create your own export tags using the following CLI commands:

```
config switch-controller switch-interface-tag
  edit <tag_name>
end
```

Use the following CLI command to list the contents of a specific VPP:

```
execute switch-controller virtual-port-pool show-by-pool <VPP_name>
```

Use the following CLI command to list all VPPs and their contents:

```
execute switch-controller virtual-port-pool show
```

NOTE: Shared ports do not support the following features:

- LLDP
- 802.1x
- STP
- BPDU guard
- Root guard
- DHCP snooping
- IGMP snooping
- QoS
- Port security
- MCLAG

sFlow support (450507)

sFlow is a method of monitoring the traffic on your network to identify areas on the network that might impact performance and throughput. With sFlow, you can export truncated packets and interface counters. FortiSwitch implements sFlow version 5 and supports trunks and VLANs.

NOTE: Because sFlow is CPU intensive, Fortinet does not recommend high rates of sampling for long periods.

sFlow uses packet sampling to monitor network traffic. The sFlow agent captures packet information at defined intervals and sends them to an sFlow collector for analysis, providing real-time data analysis. To minimize the impact on network throughput, the information sent is only a sampling of the data.

The sFlow collector is a central server running software that analyzes and reports on network traffic. The sampled packets and counter information, referred to as flow samples and counter samples, respectively, are sent as sFlow datagrams to a collector. Upon receiving the datagrams, the sFlow collector provides real-time analysis and graphing to indicate the source of potential traffic issues. sFlow collector software is available from a number of third-party software vendors. You must configure a FortiGate policy to transmit the samples from the FortiSwitch unit to the sFlow collector.

sFlow can monitor network traffic in two ways:

- Flow samples—You specify the percentage of packets (one out of n packets) to randomly sample.
- Counter samples—You specify how often (in seconds) the network device sends interface counters.

Use the following CLI commands to specify the IP address and port for the sFlow collector. By default, the IP address is 0.0.0.0, and the port number is 6343.

```
config switch-controller sflow
  collector-ip <x.x.x.x>
  collector-port <port_number>
end
```

Use the following CLI commands to configure sFlow:

```
config switch-controller managed-switch <FortiSwitch_serial_number>
  config ports
    edit <port_name>
      set sflow-sampler <disabled | enabled>
      set sflow-sample-rate <0-99999>
      set sflow-counter-interval <1-255>
    next
  next
end
```

For example:

```
config switch-controller sflow
  collector-ip 1.2.3.4
  collector-port 10
end

config switch-controller managed-switch S524DF4K15000024
  config ports
    edit port5
      set sflow-sampler enabled
      set sflow-sample-rate 10
      set sflow-counter-interval 60
    next
  next
end
```

Restricting the type of frames allowed through IEEE 802.1Q ports (448505)

You can now specify whether each FortiSwitch port discards tagged 802.1Q frames or untagged 802.1Q frames or allows all frames access to the port. By default, all frames have access to each FortiSwitch port.

Use the following CLI commands:

```
config switch-controller managed-switch <SN>
  config ports
    edit <port_name>
      set discard-mode <none | all-tagged | all-untagged>
    next
  next
end
```

Dynamic ARP inspection (DAI) support (462511)

DAI prevents man-in-the-middle attacks and IP address spoofing by checking that packets from untrusted ports have valid IP-MAC-address binding. DAI allows only valid ARP requests and responses to be forwarded.

To use DAI, you must first enable the DHCP-snooping feature, enable DAI, and then enable DAI for each VLAN. By default, DAI is disabled on all VLANs.

After enabling DHCP snooping with the `set switch-controller-dhcp-snooping enable` command, use the following CLI commands to enable DAI and then enable DAI for a VLAN:

```
config system interface
  edit vsw.test
    set switch-controller-arp-inspection <enable | disable>
  end

config switch-controller managed-switch
  edit <sn>
    config ports
      edit <VLAN_ID>
        arp-inspection-trust <untrusted | trusted>
      next
    end
  next
end
```

Use the following CLI command to check DAI statistics for a FortiSwitch unit:

```
diagnose switch arp-inspection stats <FortiSwitch_Serial_Number>
```

Use the following CLI command to delete DAI statistics for a specific VLAN:

```
diagnose switch arp-inspection stats clear <VLAN_ID> <FortiSwitch_Serial_Number>
```

FortiSwitch port mirroring support (457122)

The FortiSwitch unit can send a copy of any ingress or egress packet on a port to egress on another port of the same FortiSwitch unit. The original traffic is unaffected. This process is known as port mirroring and is typically used for external analysis and capture.

Use the following CLI commands to configure FortiSwitch port mirroring:

```
config switch-controller managed-switch
  edit <FortiSwitch_Serial_Number>
    config mirror
      edit <mirror_name>
        set status <active | inactive>
        set dst <port_name>
        set switching-packet <enable | disable>
        set src-ingress <port_name>
        set src-egress <port_name>
      next
    end
  next
end
```

NOTE: The `set status` and `set dst` commands are mandatory for port mirroring.

For example:

```
config switch-controller managed-switch
edit S524DF4K15000024
config mirror
edit 2
set status active
set dst port1
set switching-packet enable
set src-ingress port2 port3
set src-egress port4 port5
next
end
next
```

Quarantining MAC addresses (459525)

NOTE: Previously, this feature used the `config switch-controller quarantine` CLI command.

To create a permanent quarantine of specific MAC addresses, use the following CLI commands:

```
config user quarantine
set quarantine enable
config targets
edit <MAC_address>
set description <string>
set tags <tag1 tag2 tag3 ...>
next
end
end
```

Option	Description
MAC_address	A layer-2 MAC address in the following format: 12:34:56:aa:bb:cc
string	Optional. A description of the MAC address being quarantined.
tag1 tag2 tag3 ...	Optional. A list of arbitrary strings.

For example:

```
config user quarantine
set quarantine enable
config targets
edit 00:00:00:aa:bb:cc
set description "infected by virus"
set tags "quarantined"
next
end
end
```

You can add MAC addresses to be quarantined even when the quarantine feature is disabled. The MAC addresses are only quarantined when the quarantine feature is enabled.

Banning IP addresses (459525)

To temporarily ban an IP address, use the following CLI command:

```
diagnose user ban add src4 <IPv4_address>
```

Previously, this feature used the `diagnose user quarantine` CLI command.

Synchronizing the FortiGate unit with the managed FortiSwitch units (454664)

You can now synchronize the FortiGate unit with the managed FortiSwitch units to check for synchronization errors on each managed FortiSwitch unit.

Use the following command to synchronize the full configuration of a FortiGate unit with the managed FortiSwitch unit:

```
execute switch-controller trigger-config-sync <FortiSwitch_serial_number>
```

Use one of the following commands to display the synchronization state of a FortiGate unit with a specific managed FortiSwitch unit:

```
execute switch-controller get-sync-status switch-id <FortiSwitch_serial_number>
execute switch-controller get-sync-status name <FortiSwitch_name>
```

Use the following command to display the synchronization state of a FortiGate unit with a group of managed FortiSwitch units:

```
execute switch-controller get-sync-status group <FortiSwitch_group_name>
```

Use the following command to check the synchronization state of all managed FortiSwitch units in the current VDOM:

```
execute switch-controller get-sync-status all
```

For example:

```
FG100D3G14813513 (root) # execute switch-controller get-sync-status all
Managed-devices in current vdom root:

STACK-NAME: FortiSwitch-Stack-port5
SWITCH (NAME)                STATUS CONFIG      MAC-SYNC      UPGRADE
FS1D243Z14000173            Up      Idle           Idle          Idle
S124DP3X16006228 (Desktop-Switch) Up      Idle           Idle          Idle
```

Enabling the use of HTTPS to download firmware to managed FortiSwitch units (454664)

Use the following CLI commands to enable the use of HTTPS to download firmware to managed FortiSwitch units:

```
config switch-controller global
  set https-image-push enable
end
```

RADIUS accounting support (451023)

The FortiSwitch unit uses 802.1x-authenticated ports to send five types of RADIUS accounting messages to the RADIUS accounting server to support FortiGate RADIUS single sign-on:

- START—The FortiSwitch has been successfully authenticated, and the session has started.
- STOP—The FortiSwitch session has ended.
- INTERIM—Periodic messages sent based on the value set using the `set acct-interim-interval` command.
- ON—FortiSwitch will send this message when the switch is turned on.
- OFF—FortiSwitch will send this message when the switch is shut down.

Use the following commands to set up RADIUS accounting so that FortiOS can send accounting messages to managed FortiSwitch units:

```
config user radius
  edit <RADIUS_server_name>
    set acct-interim-interval <seconds>
  config accounting-server
    edit <entry_ID>
      set status {enable | disable}
      set server <server_IP_address>
      set secret <secret_key>
      set port <port_number>
    next
  end
next
end
```

FortiLink mode supported over a layer-3 network (457103)

This feature allows FortiSwitch islands (FSIs) to operate in FortiLink mode over a layer-3 network, even though they are not directly connected to the switch-controller FortiGate unit. FSIs contain one or more FortiSwitch units.

The following limitations apply to FSIs operating in FortiLink mode over a layer-3 network:

- All FortiSwitch units using this feature must be included in the FortiGate preconfigured switch table.
- No layer-2 data path component, such as VLANs, can span across layer 3 between the FortiGate unit and the FortiSwitch unit.
- All FortiSwitch units within an FSI must be connected to the same FortiGate unit.
- The FortiSwitch unit needs a functioning layer-3 routing configuration to reach the FortiGate unit or any feature-configured destination, such as syslog or 802.1x.
- Do not connect a layer-2 FortiGate unit and a layer-3 FortiGate unit to the same FortiSwitch unit.
- If the FortiSwitch management port is used for a layer-3 connection to the FortiGate unit, the FSI can contain only one FortiSwitch unit. All switch ports must remain in standalone mode.
- Do not connect a FortiSwitch unit to a layer-3 network and a layer-2 network on the same segment.
- If the network has a wide geographic distribution, some features, such as software downloads, might operate slowly.

To configure a FortiSwitch unit to operate in a layer-3 network:

1. Reset the FortiSwitch to factory default settings with the `execute factoryreset` command.
2. Manually set the FortiSwitch unit to FortiLink mode:

```
config system global
    set switch-mgmt-mode fortilink
end
```

3. Configure the discovery setting for the FortiSwitch unit. You can either use DHCP discovery or static discovery.

To use DHCP discovery:

```
config switch-controller global
    ac-discovery dhcp
        dhcp-option-code <integer>
    end
end
```

To use static discovery:

```
config switch-controller global
    ac-discovery static
        config ac-list
            id <integer>
                set ipv4-address <IPv4_address>
            next
        end
    end
end
```

4. Configure at least one port of the FortiSwitch unit as an uplink port. When the FortiSwitch is in FortiLink mode, VLAN 4094 is configured on an internal port, which can provide a path to the layer-3 network with the following commands:

```
config switch interface
    edit <port_number>
        set fortilink-l3-mode enable
    end
end
```

NOTE: The NTP server must be configured on the FortiSwitch unit either manually or provided by DHCP. The NTP server must be reachable from the FortiSwitch unit.

Limiting the number of parallel process for FortiSwitch configuration (457103)

Use the following CLI commands to reduce the number of parallel process that the switch controller uses for configuring FortiSwitch units:

```
config global
    config switch-controller system
        set parallel-process-override enable
        set parallel-process <1-300>
```

```
end
end
```

CLI changes for FortiLink mode (447349, 473773)

There are changes to the `execute switch-controller get-physical-connection`, `execute switch-controller get-conn-status`, and `diagnose switch-controller dump network-upgrade status` CLI commands.

- The `execute switch-controller get-physical-connection` CLI command has new parameters:

Use the `execute switch-controller get-physical-connection standard` command to get the FortiSwitch stack connectivity graph in the standard output format.

Use the `execute switch-controller get-physical-connection dot` command to get the FortiSwitch stack connectivity graph in a .dot (Graphviz) output format.

- The `execute switch-controller get-conn-status` CLI command output now includes virtual FortiSwitch units. Virtual FortiSwitch units are indicated by an asterisk (*) after the switch identifier. For example:

```
execute switch-controller get-conn-status

STACK-NAME: FortiSwitch-Stack-port2
SWITCH-ID      VERSION  STATUS      ADDRESS      JOIN-TIME      NAME
S108DV2EJZDAC42F v3.6.0   Authorized/Up 169.254.2.4   Thu Feb 8 17:07:35 2018 -
S108DV4FQON40Q07 v3.6.0   Authorized/Up 169.254.2.5   Thu Feb 8 17:08:37 2018 -
S108DVBWVLH4QGEB v3.6.0   Authorized/Up 169.254.2.6   Thu Feb 8 17:09:13 2018 -
S108DVCY19SA0CD8 v3.6.0   Authorized/Up 169.254.2.2   Thu Feb 8 17:04:41 2018 -
S108DVD98KMQGC44* v3.6.0   Authorized/Up 169.254.2.7   Thu Feb 8 17:10:50 2018 -
S108DVGGBJLQQO48* v3.6.0   Authorized/Up 169.254.2.3   Thu Feb 8 17:06:57 2018 -
S108DVKM5T2QEA92 v3.6.0   Authorized/Up 169.254.2.8   Thu Feb 8 17:11:00 2018 -
S108DVZX3VTA0045 v3.6.0   Authorized/Up 169.254.2.9   Thu Feb 8 17:11:00 2018 -

Managed-Switches: 8      UP: 8      DOWN: 0
```

- The `diagnose switch-controller dump network-upgrade status` CLI command output now includes the location of the image that is loaded when the FortiSwitch unit is restarted. If the Next boot column is blank, the FortiSwitch unit uses the same location each it is restarted. The status column shows the percentage downloaded, the percentage erased in flash memory, and the percentage written to flash memory.

For example:

```
diagnose switch-controller dump network-upgrade status

Running                                     Status      Next boot
-----
VDOM : root

build4277,171207 (Interim)
S108DV2EJZDAC42F S108DV-v3.6.0-build4277,171207 (Interim) (0/0/0)
```

Upgrade the firmware on multiple FortiSwitch units at the same time using the GUI (462553)

To upgrade the firmware on multiple FortiSwitch units at the same time:

- Go to *WiFi & Switch Controller > Managed FortiSwitch*.
 - Select the faceplates of the FortiSwitch units that you want to upgrade.
 - Click *Upgrade*.
- The *Upgrade FortiSwitches* page opens.

4. Select *FortiGuard* or select *Upload* and then select the firmware file to upload.
You can select only one firmware image to use to upgrade the selected FortiSwitch units. If the FortiSwitch unit already has the latest firmware image, it will not be upgraded.
5. Select *Upgrade*.

Network-assisted device detection (377467)

Network-assisted device detection allows the FortiGate unit to use the information about connected devices detected by the managed FortiSwitch unit.

To enable network-assisted device detection on a VDOM:

```
config switch-controller network-monitor-settings
    set network-monitoring enable
end
```

Connecting FortiLink ports

This section contains information about the FortiSwitch and FortiGate ports that you connect to establish a FortiLink connection.

In FortiSwitchOS 3.3.0 and later releases, you can use any of the switch ports for FortiLink. Some or all of the switch ports (depending on the model) support auto-discovery of the FortiLink ports.

You can choose to connect a single FortiLink port or multiple FortiLink ports as a logical interface (link-aggregation group, hardware switch, or software switch).

1. Enable the switch controller on the FortiGate unit

Before connecting the FortiSwitch and FortiGate units, ensure that the switch controller feature is enabled on the FortiGate unit with the FortiGate web-based manager or CLI to enable the switch controller. Depending on the FortiGate model and software release, this feature might be enabled by default.

Using the FortiGate GUI

1. Go to *System > Feature Visibility*.
2. Turn on the *Switch Controller* feature, which is in the *Basic Features* list.
3. Select *Apply*.

The menu option *WiFi & Switch Controller* now appears.

Using the FortiGate CLI

Use the following commands to enable the switch controller:

```
config system global
    set switch-controller enable
end
```

2. Connect the FortiSwitch unit and FortiGate unit

FortiSwitchOS 3.3.0 and later provides flexibility for FortiLink:

- Use any switch port for FortiLink
- Provides auto-discovery of the FortiLink ports on the FortiSwitch
- Choice of a single FortiLink port or multiple FortiLink ports in a link-aggregation group (LAG)

Auto-discovery of the FortiSwitch ports

In FortiSwitchOS 3.3.0 and later releases, D-series FortiSwitch models support FortiLink auto-discovery, on automatic detection of the port connected to the FortiGate unit.

You can use any of the switch ports for FortiLink. Before connecting the switch to the FortiGate unit, use the following FortiSwitch CLI commands to configure a port for FortiLink auto-discovery:

```
config switch interface
    edit <port>
        set auto-discovery-fortilink enable
    end
end
```

end

By default, each FortiSwitch model provides a set of ports that are enabled for FortiLink auto-discovery. If you connect the FortiLink using one of these ports, no switch configuration is required.

In FortiSwitchOS 3.4.0 and later releases, the last four ports are the default auto-discovery FortiLink ports. You can also run the `show switch interface` command on the FortiSwitch unit to see the ports that have auto-discovery enabled.

The following table lists the default auto-discovery ports for each switch model.

NOTE: Any port can be used for FortiLink if it is manually configured.

FortiSwitch Model	Default Auto-FortiLink ports
FS-108D	ports 9 and 10
FS-108D-POE	ports 9 and 10
FSR-112D	ports 9, 10, 11 and 12
FSR-112D-POE	ports 5, 6, 7, 8, 9, 10, 11, and 12
FS-124D, FS-124D-POE	ports 23, 24, 25, and 26
FS-224D-POE	ports 21, 22, 23, and 24
FS-224D-FPOE	ports 21, 22, 23, 24, 25, 26, 27, and 28
FS-248D, FS-248D-FPOE, FS-448D, FS-448D-FPOE, FS-448D-POE	ports 45, 46, 47, 48, 49, 50, 51, and 52
FS-248D-POE	ports 47, 48, 49, and 50
FS-424D, FS-424D-POE, FS-424D-FPOE	ports 23, 24, 25, and 26
FS-524D, FS-524D-FPOE	ports 21, 22, 23, 24, 25, 26, 27, 28, 29, and 30
FS-548D, FS-548D-FPOE	ports 45, 46, 47, 48, 49, 50, 51, 52, 53, and 54
FS-1024D, FS-1048D, FS-3032D	all ports

Choosing the FortiGate ports

The FortiGate unit manages all of the switches through one active FortiLink. The FortiLink can consist of one port or multiple ports (for a LAG).

As a general rule, FortiLink is supported on all ports that are not listed as HA ports.

FortiLink configuration using the FortiGate GUI

This section describes how to configure a FortiLink between a FortiSwitch unit and a FortiGate unit.

You can configure FortiLink using the FortiGate GUI or CLI. Fortinet recommends using the GUI because the CLI procedures are more complex (and therefore more prone to error).

If you use one of the auto-discovery FortiSwitch ports, you can establish the FortiLink connection (single port or LAG) with no configuration steps on the FortiSwitch and with a few simple configuration steps on the FortiGate unit.

Summary of the procedure

1. On the FortiGate unit, configure the FortLink port or create a logical FortLink interface.
2. Authorize the managed FortiSwitch unit.

Configure FortiLink as a single link

To configure the FortiLink port on the FortiGate unit:

1. Go to *Network > Interfaces*.
2. (Optional) If the FortiLink physical port is currently included in the internal interface, edit it and remove the desired port from the Physical Interface Members.
3. Edit the FortiLink port.
4. Set *Addressing mode* to *Dedicated to FortiSwitch*.
5. Configure the *IP/Network Mask* for your network.
6. Optionally select *Automatically authorize devices* or disable to manually authorize the FortiSwitch.
7. Select *OK*.

Configure FortiLink as a logical interface

You can configure the FortiLink as a logical interface: link-aggregation group (LAG), hardware switch, or software switch).

LAG is supported on all FortiSwitch models and on FortiGate models FGT-100D and above. Hardware switch is supported on some FortiGate models.

Connect any of the FortiLink-capable ports on the FortiGate unit to the FortiSwitch unit. Ensure that you configure auto-discovery on the FortiSwitch ports (unless it is so by default).

1. Go to *Network > Interfaces*.
2. (Optional) If the FortiLink physical ports are currently included in the internal interface, edit the internal interface, and remove the desired ports from the Physical Interface Members.
3. Select *Create New > Interface*.
4. Enter a name for the interface (11 characters maximum).
5. Set the *Type* to *802.3ad Aggregate*, *Hardware Switch*, or *Software Switch*.
6. Select the FortiGate ports for the logical interface.
7. Set *Addressing mode* to *Dedicated to FortiSwitch*.
8. Configure the *IP/Network Mask* for your network.

9. Optionally select *Automatically authorize devices* or disable to manually authorize the FortiSwitch.
10. Select *OK*.

FortiLink split interface

You can use the FortiLink split interface to connect the FortiLink aggregate interface from one FortiGate unit to two FortiSwitch units. When the FortiLink split interface is enabled, only one link remains active.

The aggregate interface for this configuration must contain exactly two physical ports (one for each FortiSwitch unit).

You must enable the split interface on the FortiLink aggregate interface using the FortiGate CLI:

```
config system interface
    edit <name of the FortiLink interface>
        set fortilink-split-interface enable
    end
```

Authorizing the FortiSwitch unit

If you configured the FortiLink interface to manually authorize the FortiSwitch unit as a managed switch, perform the following steps:

1. Go to *WiFi & Switch Controller > Managed FortiSwitch*.
2. Optionally, click on the FortiSwitch faceplate and click *Authorize*. This step is required only if you disabled the automatic authorization field of the interface.

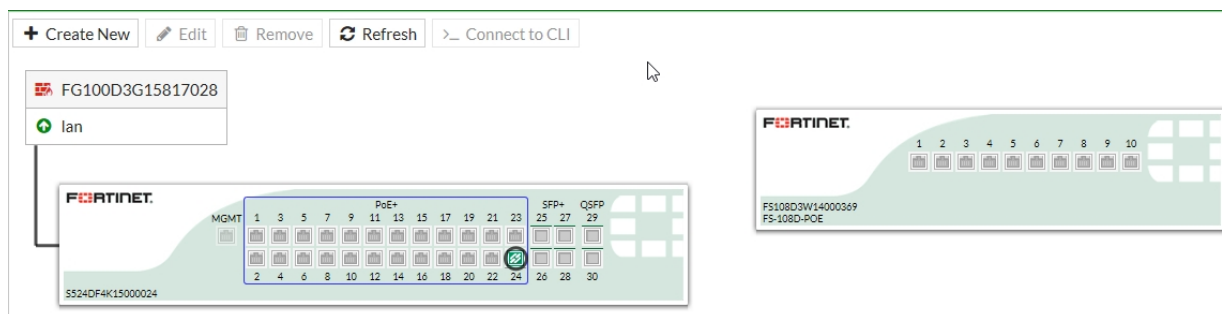

Adding preauthorized FortiSwitch units

After you preauthorize a FortiSwitch unit, you can assign the FortiSwitch ports to a VLAN.

To preauthorize a FortiSwitch:

1. Go to *WiFi & Switch Controller > Managed FortiSwitch*.
2. Click *Create New*.
3. In the New Managed FortiSwitch page, enter the serial number, model name, and description of the FortiSwitch.
4. Move the *Authorized* slider to the right.
5. Click *OK*.

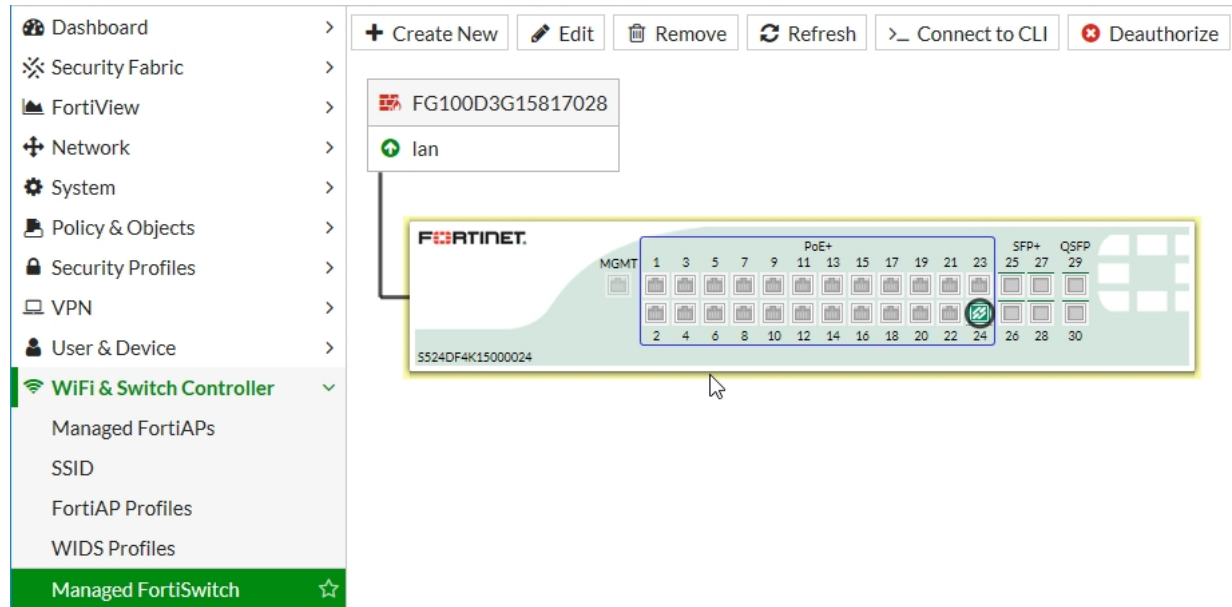

The Managed FortiSwitch page shows a FortiSwitch faceplate for the preauthorized switch.

Managed FortiSwitch display

Go to *WiFi & Switch Controller > Managed FortiSwitch* to see all of the switches being managed by your FortiGate.

When the FortiLink is established successfully, the status is green (next to the FortiGate interface name and on the FortiSwitch faceplate), and the link between the ports is a solid line.

If the link has gone down for some reason, the line will be dashed, and a broken link icon will appear. You can still edit the FortiSwitch unit though and find more information about the status of the switch. The link to the FortiSwitch unit might be down for a number of reasons; for example, a problem with the cable linking the two devices, firmware versions being out of synch, and so on. You need to make sure the firmware running on the FortiSwitch unit is compatible with the firmware running on the FortiGate unit.

From the Managed FortiSwitch page, you can edit any of the managed FortiSwitch units, remove a FortiSwitch unit from the configuration, refresh the display, connect to the CLI of a FortiSwitch unit, or deauthorize a FortiSwitch unit.

Edit a managed FortiSwitch unit

To edit a managed FortiSwitch unit:

1. Go to *Wifi & Switch Controller > Managed FortiSwitch*.
2. Click on the FortiSwitch to and click *Edit*, right-click on a FortiSwitch unit and select *Edit*, or double-click on a FortiSwitch unit.

From the *Edit Managed FortiSwitch* form, you can:

- Change the *Name* and *Description* of the FortiSwitch unit.
- View the *Status* of the FortiSwitch unit.
- *Restart* the FortiSwitch.

- *Authorize* or deauthorize the FortiSwitch.
- *Update* the firmware running on the switch.

Network interface display

On the *Network > Interfaces* page, you can see the FortiGate interface connected to the FortiSwitch unit. The GUI indicates *Dedicated to FortiSwitch* in the IP/Netmask field.

Add link aggregation groups (Trunks)

To create a link aggregation group for FortiSwitch user ports:

1. Go to *WiFi & Switch Controller > FortiSwitch Ports*.
2. Click *Create New > Trunk*.
3. In the New Trunk Group page, enter a *Name* for the trunk group.
4. Select two or more physical ports to add to the trunk group.
5. Select the *Mode*: Static, Passive LACP, or Active LACP.
6. Click OK.

New Trunk Group

Name:

Members: 🔴 port1 ✕ 🔴 port2 ✕ 🔴 port3 ✕ +

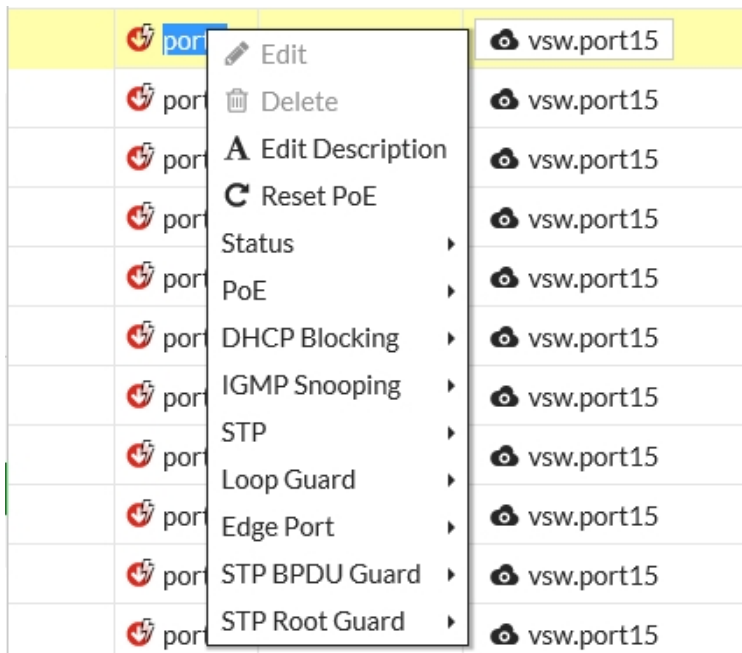

Mode: Static Passive LACP Active LACP

Configure DHCP blocking, IGMP snooping, STP, and loop guard on managed FortiSwitch ports

Go to *WiFi & Switch Controller > FortiSwitch Ports*. Right-click any port and then enable or disable the following features:

- **DHCP blocking**—The DHCP blocking feature monitors the DHCP traffic from untrusted sources (for example, typically host ports and unknown DHCP servers) that might initiate traffic attacks or other hostile actions. To prevent this, DHCP blocking filters messages on untrusted ports.
- **IGMP snooping**—IGMP snooping allows the FortiSwitch to passively listen to the Internet Group Management Protocol (IGMP) network traffic between hosts and routers. The switch uses this information to determine which ports are interested in receiving each multicast feed. FortiSwitch can reduce unnecessary multicast traffic on the LAN by pruning multicast traffic from links that do not contain a multicast listener.
- **Spanning Tree Protocol (STP)**—STP is a link-management protocol that ensures a loop-free layer-2 network topology.
- **Loop guard**—A loop in a layer-2 network results in broadcast storms that have far-reaching and unwanted effects. Fortinet loop guard helps to prevent loops. When loop guard is enabled on a switch port, the port monitors its subtending network for any downstream loops. The loop guard feature is designed to work in concert with STP rather than as a replacement for STP.
- **STP root guard**—Root guard protects the interface on which it is enabled from becoming the path to root. When enabled on an interface, superior BPDUs received on that interface are ignored or dropped. Without using root guard, any switch that participates in STP maintains the ability to reroute the path to root. Rerouting might cause your network to transmit large amounts of traffic across suboptimal links or allow a malicious or misconfigured device to pose a security risk by passing core traffic through an insecure device for packet capture or inspection. By enabling root guard on multiple interfaces, you can create a perimeter around your existing paths to root to enforce the specified network topology.
- **STP BPDU guard**—Similar to root guard, BPDU guard protects the designed network topology. When BPDU guard is enabled on STP edge ports, any BPDUs received cause the ports to go down for a specified number of minutes. The BPDUs are not forwarded, and the network edge is enforced.

STP is enabled on all ports by default. Loop guard is disabled by default on all ports.

FortiLink configuration using the FortiGate CLI

This section describes how to configure FortiLink using the FortiGate CLI. Fortinet recommends using the FortiGate GUI because the CLI procedures are more complex (and therefore more prone to error).

If you use one of the auto-discovery FortiSwitch ports, you can establish the FortiLink connection (single port or LAG) with no configuration steps on the FortiSwitch and with a few simple configuration steps on the FortiGate unit.

You can also configure FortiLink mode over a layer-3 network.

Summary of the procedure

1. Configure FortiLink on a physical port or configure FortiLink on a logical interface.
2. Configure NTP.
3. Authorize the managed FortiSwitch unit.
4. Configure DHCP.

Configure FortiLink on a physical port

Configure FortiLink on any physical port on the FortiGate unit and authorize the FortiSwitch unit as a managed switch.

In the following steps, port 1 is configured as the FortiLink port.

1. If required, remove port 1 from the `lan` interface:

```
config system virtual-switch
  edit lan
    config port
      delete port1
    end
  end
end
```

2. Configure port 1 as the FortiLink interface:

```
config system interface
  edit port1
    set auto-auth-extension-device enable
    set fortilink enable
  end
end
```

3. Configure an NTP server on port 1:

```
config system ntp
  set server-mode enable
  set interface port1
end
```

4. Authorize the FortiSwitch unit as a managed switch.

```
config switch-controller managed-switch
  edit FS224D3W14000370
```

```

        set fsw-wan1-admin enable
    end
end

```

NOTE: The FortiSwitch unit will reboot when you issue the `set fsw-wan1-admin enable` command.

Configure FortiLink on a logical interface

You can configure FortiLink on a logical interface: link-aggregation group (LAG), hardware switch, or software switch).

NOTE: LAG is supported on all FortiSwitch models and on FortiGate models FGT-100D and above. Hardware switch is supported on some FortiGate models.

Connect any of the FortiLink-capable ports on the FortiGate to the FortiSwitch. Ensure that you configure auto-discovery on the FortiSwitch ports (unless it is auto-discovery by default).

In the following procedure, port 4 and port 5 are configured as a FortiLink LAG.

1. If required, remove the FortiLink ports from the **lan** interface:

```

config system virtual-switch
    edit lan
        config port
            delete port4
            delete port5
        end
    end
end

```

2. Create a trunk with the two ports that you connected to the switch:

```

config system interface
    edit flink1 (enter a name, 11 characters maximum)
        set ip 169.254.3.1 255.255.255.0
        set allowaccess ping capwap https
        set vlanforward enable
        set type aggregate
        set member port4 port5
        set lacp-mode static
        set fortilink enable
        (optional) set fortilink-split-interface enable
    next
end

```

NOTE: If the members of the aggregate interface connect to more than one FortiSwitch, you must enable `fortilink-split-interface`.

3. Authorize the FortiSwitch unit as a managed switch.

```

config switch-controller managed-switch
    edit FS224D3W14000370
        set fsw-wan1-admin enable
    end
end

```

NOTE: FortiSwitch will reboot when you issue the `set fsw-wan1-admin enable` command.

Enable multiple FortiLink interfaces

NOTE: Only the first FortiLink interface has GUI support.

Use the following command to enable or disable multiple FortiLink interfaces.

```
config switch-controller global
    set allow-multiple-interfaces {enable | disable}
end
```

FortiLink mode over a layer-3 network

This feature allows FortiSwitch islands (FSIs) to operate in FortiLink mode over a layer-3 network, even though they are not directly connected to the switch-controller FortiGate unit. FSIs contain one or more FortiSwitch units.

The following limitations apply to FSIs operating in FortiLink mode over a layer-3 network:

- All FortiSwitch units using this feature must be included in the FortiGate preconfigured switch table.
- No layer-2 data path component, such as VLANs, can span across layer 3 between the FortiGate unit and the FortiSwitch unit.
- All FortiSwitch units within an FSI must be connected to the same FortiGate unit.
- The FortiSwitch unit needs a functioning layer-3 routing configuration to reach the FortiGate unit or any feature-configured destination, such as syslog or 802.1x.
- Do not connect a layer-2 FortiGate unit and a layer-3 FortiGate unit to the same FortiSwitch unit.
- If the FortiSwitch management port is used for a layer-3 connection to the FortiGate unit, the FSI can contain only one FortiSwitch unit. All switch ports must remain in standalone mode.
- Do not connect a FortiSwitch unit to a layer-3 network and a layer-2 network on the same segment.
- If the network has a wide geographic distribution, some features, such as software downloads, might operate slowly.

To configure a FortiSwitch unit to operate in a layer-3 network:

1. Reset the FortiSwitch to factory default settings with the `execute factoryreset` command.
2. Manually set the FortiSwitch unit to FortiLink mode:

```
config system global
    set switch-mgmt-mode fortilink
end
```

3. Configure the discovery setting for the FortiSwitch unit. You can either use DHCP discovery or static discovery.

To use DHCP discovery:

```
config switch-controller global
    ac-discovery dhcp
        dhcp-option-code <integer>
    end
end
```

To use static discovery:

```
config switch-controller global
    ac-discovery static
        config ac-list
            id <integer>
                set ipv4-address <IPv4_address>
            next
        end
    end
end
```

4. Configure at least one port of the FortiSwitch unit as an uplink port. When the FortiSwitch is in FortiLink mode, VLAN 4094 is configured on an internal port, which can provide a path to the layer-3 network with the following commands:

```
config switch interface
    edit <port_number>
        set fortilink-l3-mode enable
    end
end
```

NOTE: The NTP server must be configured on the FortiSwitch unit either manually or provided by DHCP. The NTP server must be reachable from the FortiSwitch unit.

Network topologies for managed FortiSwitch units

The FortiGate unit requires only one active FortiLink to manage all of the subtending FortiSwitch units (called *stacking*).

You can configure the FortiLink as a physical interface or as a logical interface (associated with one or more physical interfaces). Depending on the network topology, you can also configure a standby FortiLink.

NOTE: For any of the topologies:

- All of the managed FortiSwitch units will function as one Layer-2 stack where the FortiGate unit manages each FortiSwitch separately.
- The active FortiLink carries data as well as management traffic.

Supported topologies

Fortinet recommends the following topologies for managed FortiSwitch units:

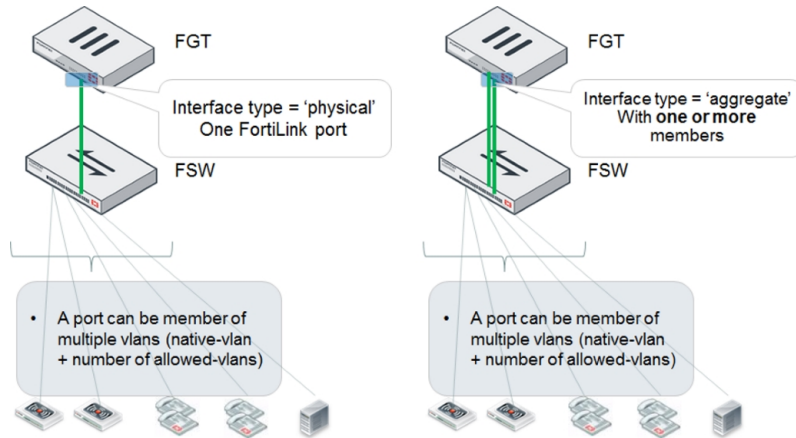

- [Single FortiGate managing a single FortiSwitch unit on page 1931](#)
- [Single FortiGate unit managing a stack of several FortiSwitch units on page 1932](#)
- [HA-mode FortiGate units managing a single FortiSwitch unit on page 1933](#)
- [HA-mode FortiGate units managing a stack of several FortiSwitch units on page 1934](#)
- [HA-mode FortiGate units managing a FortiSwitch two-tier topology on page 1935](#)
- [Single FortiGate unit managing multiple FortiSwitch units \(using a hardware or software switch interface\) on page 1936](#)
- [HA-mode FortiGate units managing two-tier FortiSwitch units with access rings on page 1937](#)
- [Dual-homed servers connected to FortiLink tier-1 FortiSwitch units using an MCLAG on page 1938](#)
- [Standalone FortiGate unit with dual-homed FortiSwitch access on page 1939](#)
- [HA-mode FortiGate units with dual-homed FortiSwitch access on page 1940](#)
- [Multi-tiered MCLAG with HA-mode FortiGate units on page 1941](#)

Single FortiGate managing a single FortiSwitch unit

On the FortiGate unit, the FortiLink interface is configured as physical or aggregate. The 802.3ad aggregate interface type provides a logical grouping of one or more physical interfaces.

NOTE:

- For the aggregate interface, you must disable the split interface on the FortiGate unit.
- When you are using the aggregate interface on the FortiGate unit for the FortiLink interface, the `lacp-mode` of the FortiLink aggregate interface must be set to `static`.

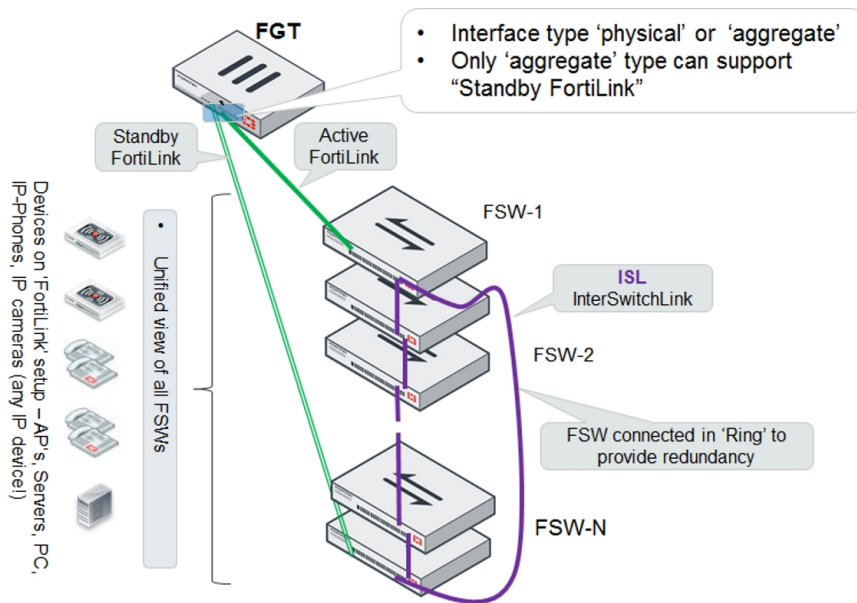

Single FortiGate unit managing a stack of several FortiSwitch units

The FortiGate unit connects directly to one FortiSwitch unit using a physical or aggregate interface. The remaining FortiSwitch units connect in a ring using inter-switch links (that is, ISL).

Optionally, you can connect a standby FortiLink connection to the last FortiSwitch unit. For this configuration, you create a FortiLink Split-Interface (an aggregate interface that contains one active link and one standby link).

NOTE:

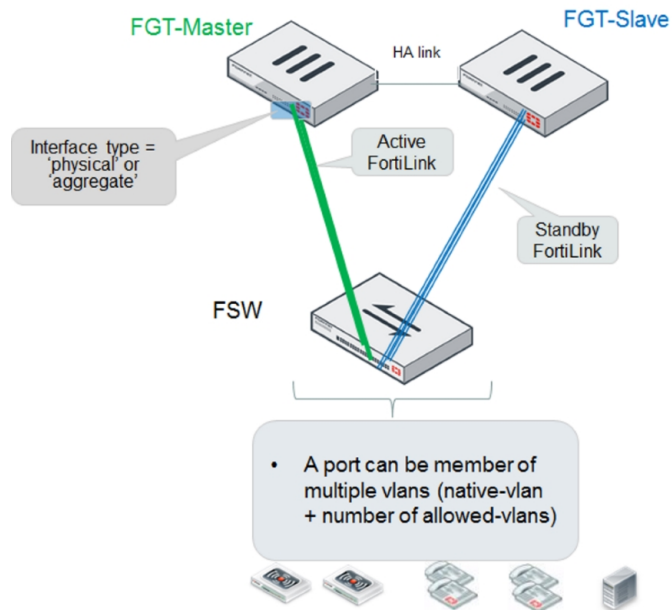

- When you are using the aggregate interface on the FortiGate unit for the FortiLink interface, the `lacp-mode` of the FortiLink aggregate interface must be set to `static`.
- External devices shown in the following topology must be compliant endpoints, such as computers. They cannot be third-party switches or appliances.

HA-mode FortiGate units managing a single FortiSwitch unit

The master and slave FortiGate units both connect a FortiLink to the FortiSwitch unit. The FortiLink port(s) and interface type must match on the two FortiGate units.

NOTE: When using HA-mode FortiGate units to manage FortiSwitch units, the HA mode must be active-passive.

HA-mode FortiGate units managing a stack of several FortiSwitch units

The master and slave FortiGate units both connect a FortiLink to the first FortiSwitch unit and (optionally) to the last FortiSwitch unit. The FortiLink ports and interface type must match on the two FortiGate units.

For the active/standby FortiLink configuration, you create a FortiLink Split-Interface (an aggregate interface that contains one active link and one standby link).

NOTE:

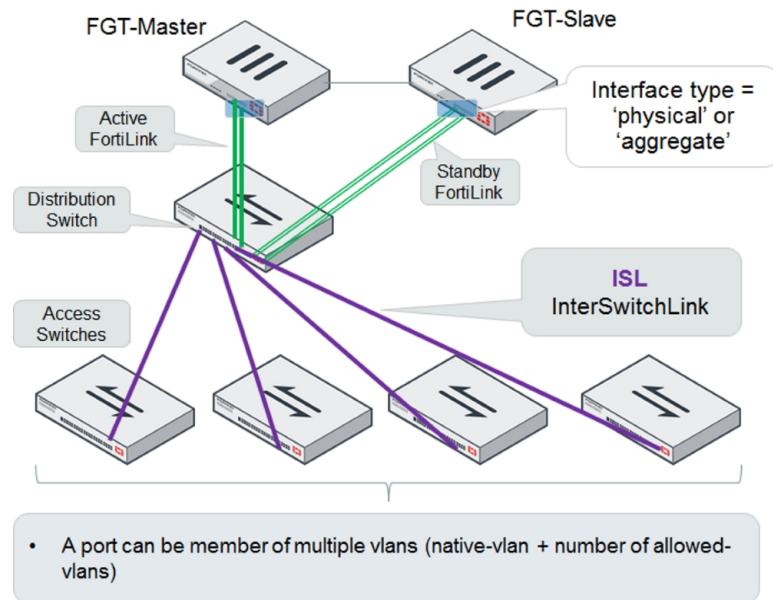

- When you are using the aggregate interface on the FortiGate unit for the FortiLink interface, the `lacp-mode` of the FortiLink aggregate interface must be set to `static`.
- When using HA-mode FortiGate units to manage FortiSwitch units, the HA mode must be active-passive.

HA-mode FortiGate units managing a FortiSwitch two-tier topology

The distribution FortiSwitch unit connects to the master and slave FortiGate units. The FortiLink port(s) and interface type must match on the two FortiGate units.

NOTE: When using HA-mode FortiGate units to manage FortiSwitch units, the HA mode must be active-passive.

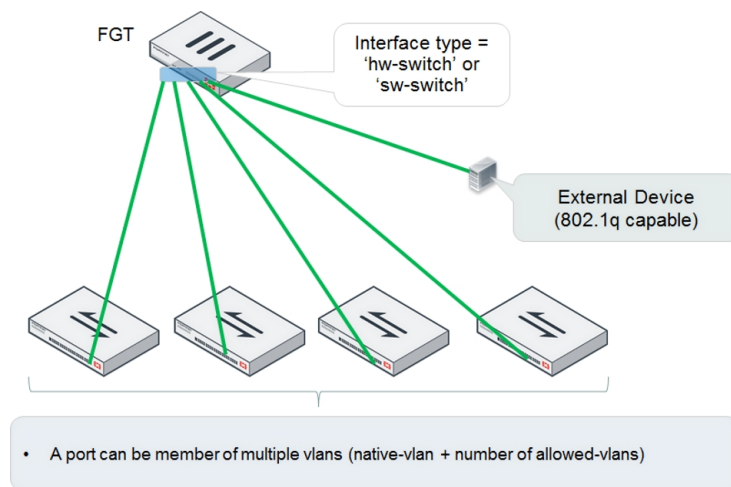

Single FortiGate unit managing multiple FortiSwitch units (using a hardware or software switch interface)

The FortiGate unit connects directly to each FortiSwitch unit. Each of these FortiLink ports is added to the logical hardware-switch or software-switch interface on the FortiGate unit.

Optionally, you can connect other devices to the FortiGate logical interface. These devices, which must support IEEE 802.1q VLAN tagging, will have Layer 2 connectivity with the FortiSwitch ports.

NOTE: Using the hardware or software switch interface in FortiLink mode is not recommended in most cases. It can be used when the traffic on the ports is very light because all traffic across the switches moves through the FortiGate unit.

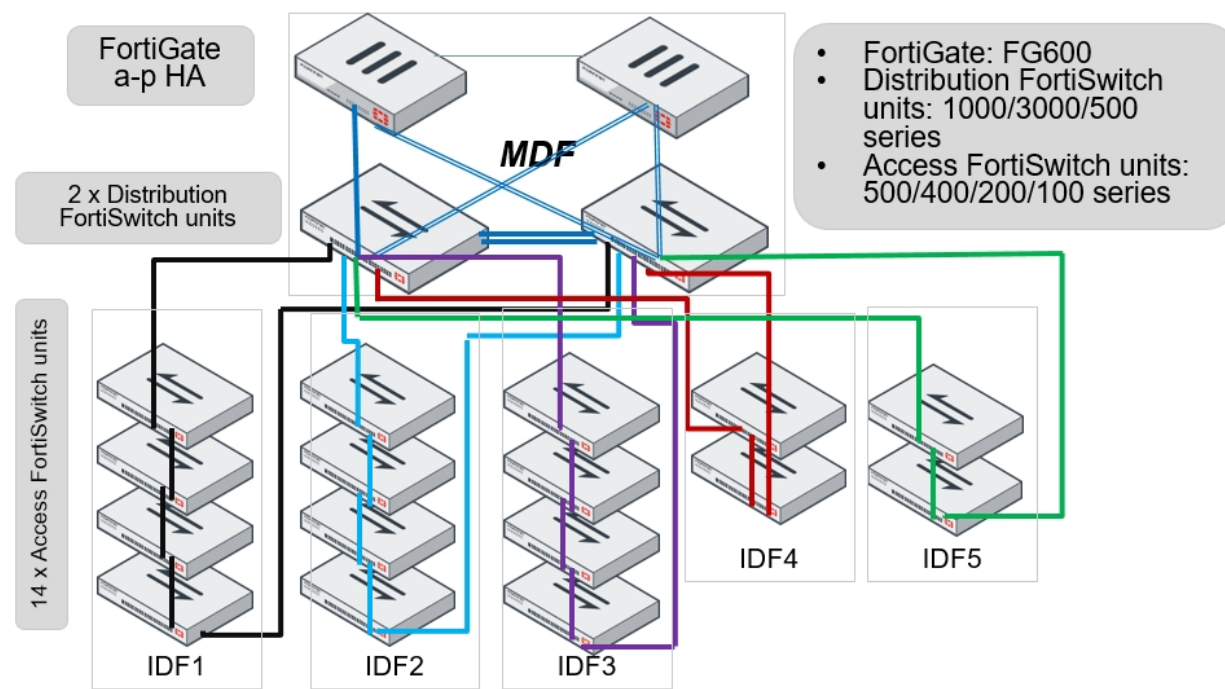

HA-mode FortiGate units managing two-tier FortiSwitch units with access rings

HA-mode FortiGate units connect to redundant distribution FortiSwitch units. Access FortiSwitch units are arranged in a stack in each IDF, connected to both distribution switches.

For the FortiLink connection to each distribution switch, you create a FortiLink split interface (an aggregate interface that contains one active link and one standby link).

NOTE:

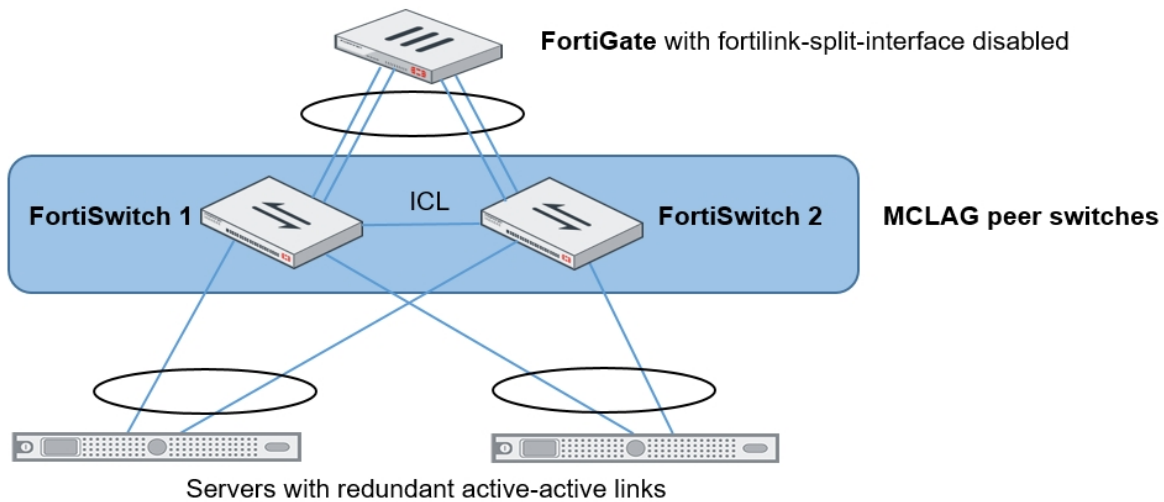

- Before FortiSwitchOS 3.6.4, MCLAG was not supported when access rings were present. Starting with FortiSwitchOS 3.6.4, MCLAG is supported, even with access rings present.
- When using HA-mode FortiGate units to manage FortiSwitch units, the HA mode must be active-passive.
- When you are using the aggregate interface on the FortiGate unit for the FortiLink interface, the `lacp-mode` of the FortiLink aggregate interface must be set to `static`.
- This is only an example topology. Other combinations of FortiGate units and FortiSwitch units can be used to create a similar topology.

Dual-homed servers connected to FortiLink tier-1 FortiSwitch units using an MCLAG

To configure a multichassis LAG, you need to configure FortiSwitch 1 and FortiSwitch 2 as MCLAG peer switches before creating a two-port LAG. Use the `set mclag-icl enable` command to create an inter-chassis link (ICL) on each FortiSwitch unit. Then you set up two MCLAGs towards the servers, each MCLAG using one port from each FortiSwitch unit. You must disable the FortiLink split interface for the FortiGate unit.

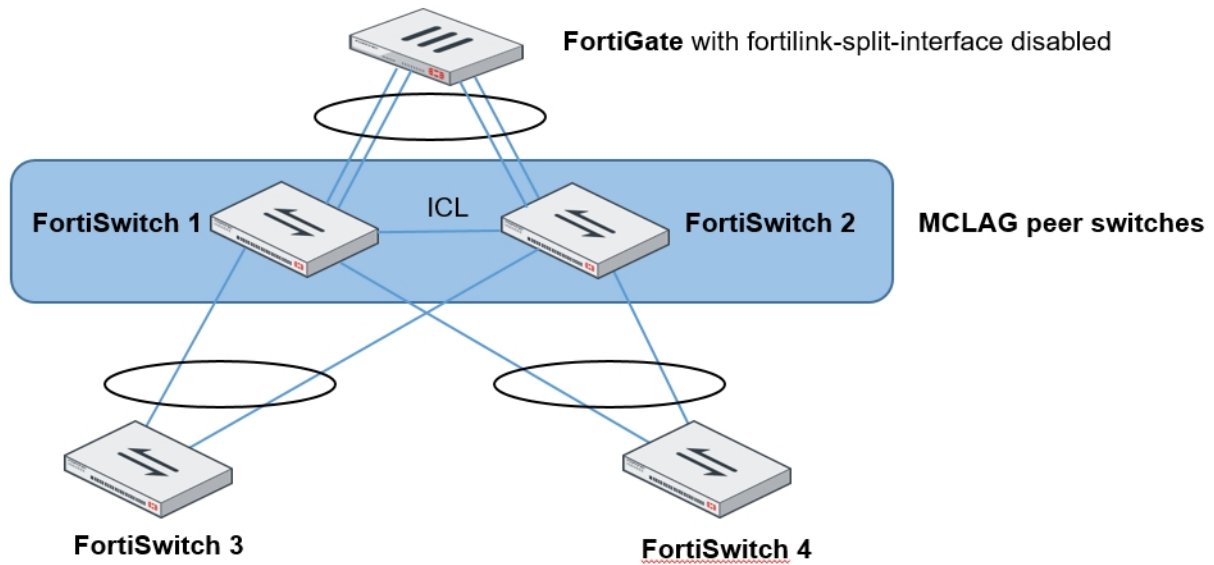

This topology is supported when the FortiGate unit is in HA mode.

Standalone FortiGate unit with dual-homed FortiSwitch access

This network topology provides high port density with two tiers of FortiSwitch units.

Use the `set mclag-icl enable` command to create an ICL on each FortiSwitch unit.

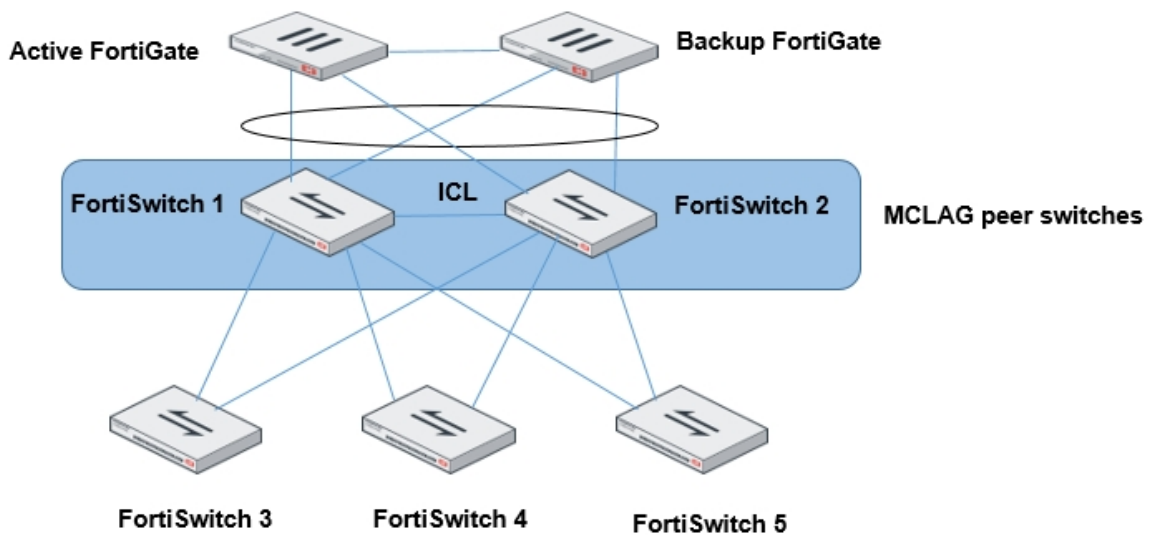

HA-mode FortiGate units with dual-homed FortiSwitch access

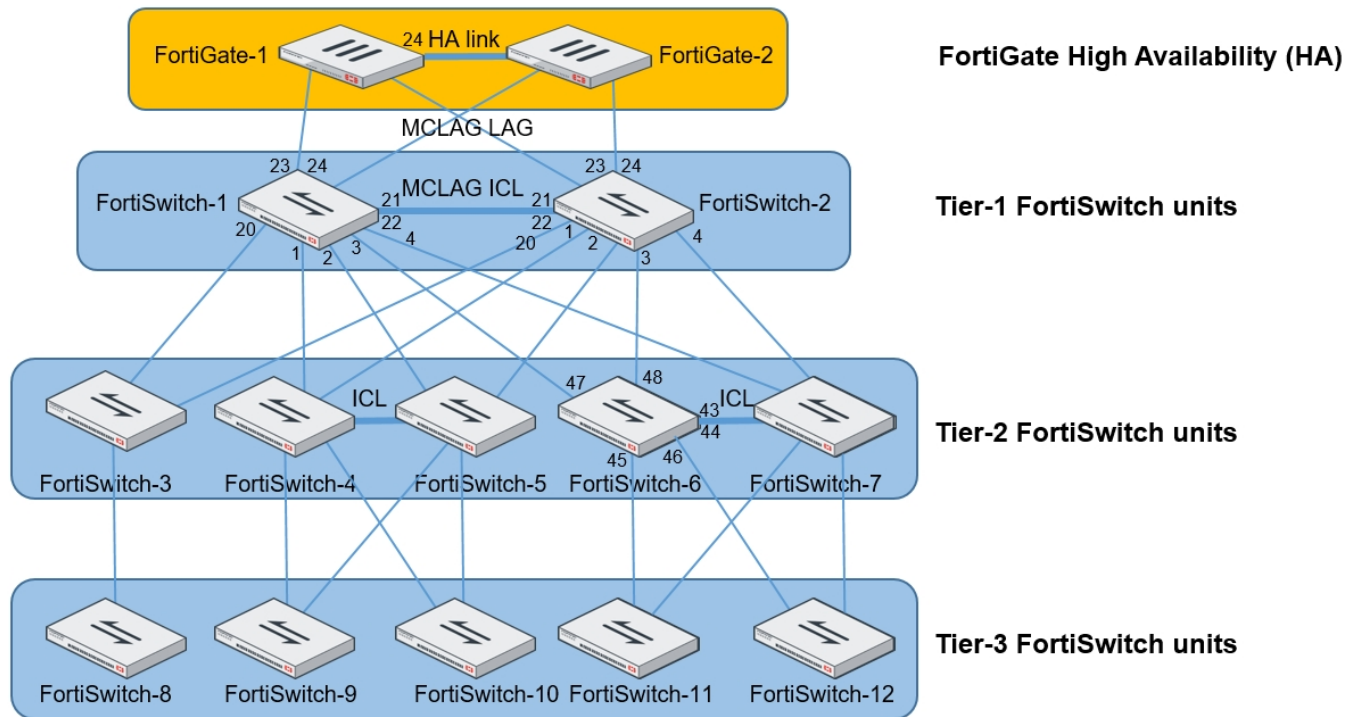

In HA mode, only one FortiGate is active at a time. If the active FortiGate unit fails, the backup FortiGate unit becomes active.

Use the `set mclag-icl enable` command to create an ICL on each FortiSwitch unit.

NOTE: When using HA-mode FortiGate units to manage FortiSwitch units, the HA mode must be active-passive.

Multi-tiered MCLAG with HA-mode FortiGate units

NOTE:

- When using HA-mode FortiGate units to manage FortiSwitch units, the HA mode must be active-passive.
- In this topology, you must use the `auto-isl-port-group` setting as described in the following configuration example. This setting instructs the switches to group ports from MCLAG peers together into one MCLAG when the inter-switch link (ISL) is formed.
- The inter-chassis link (ICL) and `auto-isl-port-group` settings must be done directly on the FortiSwitch unit.
- CLI commands in red are manually configured.
- In a two-tier MCLAG topology, disable STP on the first tier MCLAG peer group with the following commands on each peer switch and do not use access-ring connections on first tier MCLAG peer groups:

```
config switch global
    set mclag-stp-aware disable
end
```

To configure a multi-tiered MCLAG with HA-mode FortiGate units:

1. Configure FortiSwitch-1 for the tier-1 MCLAG:
 - a. Enable the ICL on the ISL formed with the MCLAG peer switch:

```
config switch trunk
    edit "D243Z14000288-0" // trunk name derived from FortiSwitch-2 SN
        set mode lacp-active
        set auto-isl 1
        set mclag-icl enable
```

```
        set members "port21" "port22"
    end
```

- b. Configure the two auto-isl-port-groups based on the topology diagram. The group name must match the name that is configured on the peer switch.

```
config switch auto-isl-port-group
edit "mclag-core1"
    set members "port1" "port2"
next
edit "mclag-core2"
    set members "port3" "port4"
end
```

- c. After you complete the CLI commands in Steps 1a and 1b, the trunks are automatically formed:

```
config switch trunk
edit "D243Z14000288-0"
    set mode lacp-active
    set auto-isl 1
    set mclag-icl enable
    set members "port21" "port22"
next
edit "__FoRtIiLiNk0__"
    set mclag enable
    set members "port24" "port23"
next
edit "8DN4K16000360-0" // trunk name derived from FortiSwitch-3 SN
    set mode lacp-active
    set auto-isl 1
    set mclag enable
    set members "port20"
next
edit "mclag-core1"
    set mode lacp-active
    set auto-isl 1
    set mclag enable
    set members "port1" "port2"
next
edit "mclag-core2"
    set mode lacp-active
    set auto-isl 1
    set mclag enable
    set members "port3" "port4"
next
end
```

2. Configure FortiSwitch-2 for the tier-1 MCLAG:

- a. Enable the ICL on the ISL formed with the MCLAG peer switch:

```
config switch trunk
edit "D243Z14000289-0" // trunk name derived from FortiSwitch-1 SN
    set mode lacp-active
```

```

        set auto-isl 1
        set mclag-icl enable
        set members "port21" "port22"
    end

```

- b. Configure the two auto-isl-port-groups based on the topology diagram. The group name must match the name that is configured on the peer switch.

```

config switch auto-isl-port-group
    edit "mclag-core1"
        set members "port1" "port2"
    next
    edit "mclag-core2"
        set members "port3" "port4"
    end

```

- c. After you complete the CLI commands in Steps 2a and 2b, the trunks are automatically formed:

```

config switch trunk
    edit "D243Z14000288-0"
        set mode lacp-active
        set auto-isl 1
        set mclag-icl enable
        set members "port21" "port22"
    next
    edit "__FoRtI1LiNk0__"
        set mclag enable
        set members "port24" "port23"
    next
    edit "8DN4K16000360-0" // trunk name derived from FortiSwitch-3 SN
        set mode lacp-active
        set auto-isl 1
        set mclag enable
        set members "port20"
    next
    edit "mclag-core1"
        set mode lacp-active
        set auto-isl 1
        set mclag enable
        set members "port1" "port2"
    next
    edit "mclag-core2"
        set mode lacp-active
        set auto-isl 1
        set mclag enable
        set members "port3" "port4"
    next
end

```

3. Tier-2 MLAGs. Enable the ICL between the MLAG peers. For example, configure FortiSwitch-6 as follows.
 - a. Change the tier-2 MLAG peer switches to FortiLink mode and connect them to each other. Enable the ICL on the ISL formed with the MLAG peer switches.

```
config switch trunk
    edit "8DN3X15000026-0" // trunk name derived from FortiSwitch-7 SN
        set mode lacp-active
        set auto-isl 1
        set mclag-icl enable
        set members "port43" "port44"
    end
```

b. The trunks are automatically formed as below:

```
config switch trunk
    edit "8DN3X15000026-0"
        set mode lacp-active
        set auto-isl 1
        set mclag-icl enable
        set members "port43" "port44"
    next
    edit "8EP3X17000051-0" // trunk name derived from FortiSwitch-11 SN
        set mode lacp-active
        set auto-isl 1
        set mclag enable
        set members "port45"
    next
    edit "_FlInK1_MLAG0_"
        set mode lacp-active
        set auto-isl 1
        set mclag enable
        set members "port48" "port47"
    next
    edit "8EP3X17000069-0" // trunk name derived from FortiSwitch-12 SN
        set mode lacp-active
        set auto-isl 1
        set mclag enable
        set members "port46"
    next
end
```

4. Access FortiSwitch units. The access switch trunks are formed automatically as below.

On FortiSwitch-11:

```
config switch trunk
    edit "_FlInK1_MLAG0_"
        set mode lacp-active
        set auto-isl 1
        set mclag enable
        set members "port48" "port47"
    next
end
```

On FortiSwitch-12:

```
config switch trunk
    edit "_FlInK1_MLAG0_"
        set mode lacp-active
        set auto-isl 1
        set mclag enable
        set members "port47" "port48"
    next
end
```

Grouping FortiSwitch units

You can simplify the configuration and management of complex topologies by creating FortiSwitch groups. A group can include one or more FortiSwitch units and you can include different models in a group.

```
config switch-controller switch-group
  edit <name>
    set description <string>
    set members <serial-number> <serial-number> ...
  end
end
```

Grouping FortiSwitch units allows you to restart all of the switches in the group instead of individually. For example, you can use the following command to restart all of the FortiSwitch units in a group named `my-switch-group`:

```
execute switch-controller restart-swtp my-switch-group
```

Upgrading the firmware of FortiSwitch groups is easier, too, because fewer commands are needed. See [Firmware upgrade of stacked or tiered FortiSwitch units on page 1947](#).

Stacking configuration

To set up stacking:

1. Configure the active FortiLink interface on the FortiGate unit.
2. (Optional) Configure the standby FortiLink interface.
3. Connect the FortiSwitch units together, based on your chosen topology.

1. Configure the active FortiLink

Configure the FortiLink interface (as described in the [FortiLink configuration using the FortiGate GUI](#) chapter).

When you configure the FortiLink interface, the stacking capability is enabled automatically.

2. Configure the standby FortiLink

Configure the standby FortiLink interface. Depending on your configuration, the standby FortiLink might connect to the same FortiGate unit as the active FortiLink or to a different FortiGate unit.

If the FortiGate unit receives discovery requests from two FortiSwitch units, the link from one FortiSwitch unit will be selected as active, and the link from other FortiSwitch unit will be selected as standby.

If the active FortiLink fails, the FortiGate unit converts the standby FortiLink to active.

3. Connect the FortiSwitch units

Refer to the topology diagrams to see how to connect the FortiSwitch units.

Inter-switch links (ISLs) form automatically between the stacked switches.

The FortiGate unit will discover and authorize all of the FortiSwitch units that are connected. After this, the FortiGate unit is ready to manage all of the authorized FortiSwitch units.

Disable stacking

To disable stacking, execute the following commands from the FortiGate CLI. In the following example, port4 is the FortiLink interface:

```
config system interface
  edit port4
    set fortilink-stacking disable
  end
end
```

Firmware upgrade of stacked or tiered FortiSwitch units

In this topology, the core FortiSwitch units are model FS-224D-FPOE, and the access FortiSwitch units are model FS-124D-POE. Because the switches are stacked or tiered, the procedure to update the firmware is simpler. In the following procedure, the four FortiSwitch units are upgraded from 3.6.1 to 3.6.2.

To upgrade the firmware of stacked or tiered FortiSwitch units:

- 1. Check that all of the FortiSwitch units are connected and which firmware versions they are running. For example:

```
execute switch-controller get-conn-status

STACK-NAME: FortiSwitch-Stack-port2
SWITCH-ID      VERSION  STATUS      ADDRESS      JOIN-TIME
NAME
S108DV2EJZDAC42F v3.6.0   Authorized/Up 169.254.2.4   Thu Feb  8 17:07:35 2018
-
S108DV4FQON40Q07 v3.6.0   Authorized/Up 169.254.2.5   Thu Feb  8 17:08:37 2018
-
S108DVBWVLH4QGEB v3.6.0   Authorized/Up 169.254.2.6   Thu Feb  8 17:09:13 2018
-
S108DVCY19SA0CD8 v3.6.0   Authorized/Up 169.254.2.2   Thu Feb  8 17:04:41 2018
-
S108DVD98KMQGC44* v3.6.0   Authorized/Up 169.254.2.7   Thu Feb  8 17:10:50 2018
-
S108DVGGBJLQQO48* v3.6.0   Authorized/Up 169.254.2.3   Thu Feb  8 17:06:57 2018
-
```

```

S108DVKM5T2QEA92   v3.6.0   Authorized/Up   169.254.2.8   Thu Feb  8 17:11:00 2018
-
S108DVZX3VTA0045   v3.6.0   Authorized/Up   169.254.2.9   Thu Feb  8 17:11:00 2018
-

Managed-Switches:  8      UP:  8      DOWN:  0

```

2. Upload the firmware image for each FortiSwitch model (FS-224D-FPOE and FS-124D-POE) from either an FTP or TFTP server. If you are using a virtual domain (VDOM), you must enter the `config global` command before entering the `upload-swtp-image` command. For example:

```

FG100E4Q16004478 (global) # execute switch-controller upload-swtp-image tftp FSW_124D_POE-
v3-build0382-FORTINET.out 172.30.12.18

Downloading file FSW_124D_POE-v3-build0382-FORTINET.out from tftp server 172.30.12.18...
#####
Image checking ...
Image MD5 calculating ...
Image Saving S124DP-IMG.swtp ...
Successful!

File Syncing...

FG100E4Q16004478 (global) # execute switch-controller upload-swtp-image tftp FSW_224D_FPOE-
v3-build0382-FORTINET.out 172.30.12.18

Downloading file FSW_224D_FPOE-v3-build0382-FORTINET.out from tftp server 172.30.12.18...
#####
Image checking ...
Image MD5 calculating ...
Image Saving S224DF-IMG.swtp ...
Successful!

File Syncing...

```

3. Check which firmware images are available. For example:

```

FG100E4Q16004478 (root) # execute switch-controller list-swtp-image
SWTP Images on AC:

```

ImageName	ImageSize(B)	ImageInfo	ImageMTime
S124DP-IMG.swtp	19174985	S124DP-v3.6-build382	Mon Oct 2 14:40:54 2017
S224DF-IMG.swtp	23277106	S224DF-v3.6-build382	Mon Oct 2 14:42:55 2017

4. Stage the firmware image for each FortiSwitch model (FS-224D-FPOE and FS-124D-POE). For example:

```

FG100E4Q16004478 (root) # execute switch-controller stage-tiered-swtp-image ALL S124DP-
IMG.swtp
Staged Image Version S124DP-v3.6-build382

FG100E4Q16004478 (root) # execute switch-controller stage-tiered-swtp-image ALL S224DF-
IMG.swtp
Staged Image Version S224DF-v3.6-build382

```

5. Check that the correct firmware image is staged for each FortiSwitch unit. For example:

```

diagnose switch-controller dump network-upgrade status

```

	Running	Status	Next boot

VDOM : root			
S108DVCY19SA0CD8	S108DV-v3.6.0-build4277,171207 (Interim)	(0/0/0)	S108DV-v3.7.0-
build4277,171207	(Interim)		
S108DV2EJZDAC42F	S108DV-v3.6.0-build4277,171207 (Interim)	(0/0/0)	

6. Restart the FortiSwitch units after a 2-minute delay. For example:

```

execute switch-controller restart-swtp-delayed ALL

```

7. When the FortiSwitch units are running again, check that they are running the new firmware version. For example:

```
execute switch-controller get-conn-status
```

```
STACK-NAME: FortiSwitch-Stack-port2
```

SWITCH-ID	VERSION	STATUS	ADDRESS	JOIN-TIME

```
Managed-Switches: 8      UP: 8      DOWN: 0
```

Transitioning from a FortiLink split interface to a FortiLink MCLAG

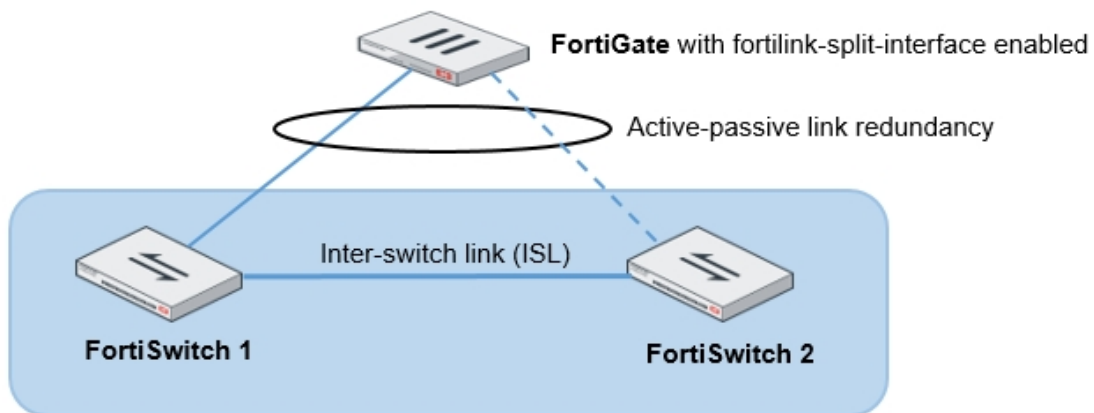

In this topology, the FortiLink split interface connects a FortiLink aggregate interface from one FortiGate unit to two FortiSwitch units.

NOTE:

- This procedure also applies to a FortiGate unit in HA mode.
- More links can be added between the FortiGate unit and FortiSwitch unit.
- After the MCLAG is set up, only connect the tier-2 FortiSwitch units.
- When you are using the aggregate interface on the FortiGate unit for the FortiLink interface, the `lacp-mode` of the FortiLink aggregate interface must be set to `static`.

1. Enable the split interface on the FortiLink aggregate interface. By default, the split interface is enabled. For example:

```
config system interface
  edit flinksplit1
    set ip 169.254.3.1 255.255.255.0
    set allowaccess ping capwap https
    set vlanforward enable
    set type aggregate
    set member port4 port5
    set lacp-mode static
    set fortilink enable
    set fortilink-split-interface enable
  next
end
```

2. Log into FortiSwitch 2 using the **Connect to CLI** button in the FortiGate GUI, use the `get switch lldp auto-isl-status` command to find out the name of the trunk connecting the peer switches, and change the ISL to an ICL. For example:

```
get switch lldp auto-isl-status

config switch trunk
  edit <trunk_name>
    set mclag-icl enable
```

```

    next
end

```

3. Log into FortiSwitch 1 using the *Connect to CLI* button in the FortiGate GUI, use the `get switch lldp auto-isl-status` command to find out the name of the trunk connecting the peer switches, and change the ISL to an ICL. For example:

```

get switch lldp auto-isl-status

config switch trunk
    edit <trunk_name>
        set mclag-icl enable
    next
end

```

4. Log into the FortiGate unit and disable the split interface. For example:

```

config system interface
    edit flinksplit1
        set fortilink-split-interface disable
    next
end

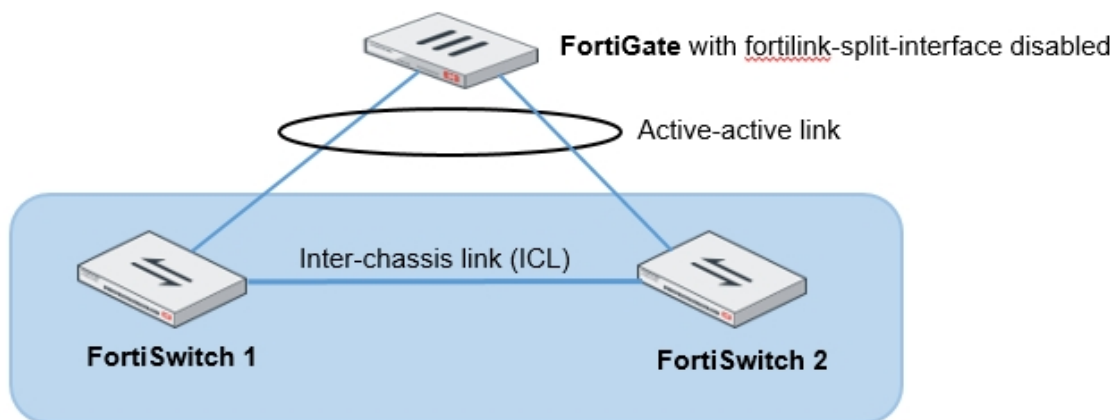

```

5. Enable the LACP active mode.
6. Check that the LAG is working correctly. For example:

```

diagnose netlink aggregate name <aggregate_name>

```

Optional setup tasks

This section describes the following tasks:

- [Configuring the FortiSwitch management port on page 1952](#)
- [Converting to FortiSwitch standalone mode on page 1953](#)
- [Changing the admin password on the FortiGate for all managed FortiSwitch units on page 1953](#)
- [Enabling network-assisted device detection on page 1954](#)
- [Limiting the number of parallel process for FortiSwitch configuration on page 1954](#)

Configuring the FortiSwitch management port

If the FortiSwitch model has a dedicated management port, you can configure remote management to the FortiSwitch. In FortiLink mode, the FortiGate is the default gateway, so you need to configure an explicit route for the FortiSwitch management port.

Using the Web administration GUI

1. Go to *Network > Static Routes > Create New > Route*.
2. Set *Destination* to *Subnet* and enter a subnetwork and mask.
3. Set *Device* to the management interface.
4. Add a *Gateway* IP address.

Using the FortiSwitch CLI

Enter the following commands:

```
config router static
  edit 1
    set device mgmt
    set gateway <router IP address>
    set dst <router subnet> <subnet mask>
  end
end
```

In the following example, the FortiSwitch management port is connected to a router with IP address 192.168.0.10:

```
config router static
  edit 1
    set device mgmt
    set gateway 192.168.0.10
    set dst 192.168.0.0 255.255.0.0
  end
end
```

Converting to FortiSwitch standalone mode

Use one of the following commands to convert a FortiSwitch from FortiLink mode to standalone mode so that it will no longer be managed by a FortiGate:

- `execute switch-controller factory-reset <switch-id>`
This command returns the FortiSwitch to the factory defaults and then reboots the FortiSwitch. If the FortiSwitch is configured for FortiLink auto-discovery, FortiGate can detect and automatically authorize the FortiSwitch. For example:
`execute switch-controller factory-reset S1234567890`
- `execute switch-controller set-standalone <switch-id>`
This command returns the FortiSwitch to the factory defaults, reboots the FortiSwitch, and prevents the FortiGate from automatically detecting and authorizing the FortiSwitch. For example:
`execute switch-controller set-standalone S1234567890`

You can disable FortiLink auto-discovery on multiple FortiSwitch units using the following commands:

```
config switch-controller global
    set disable-discovery <switch-id>
end
```

For example:

```
config switch-controller global
    set disable-discovery S1234567890
end
```

You can also add or remove entries from the list of FortiSwitch units that have FortiLink auto-discovery disabled using the following commands:

```
config switch-controller global
    append disable-discovery <switch-id>
    unselect disable-discovery <switch-id>
end
```

For example:

```
config switch-controller global
    append disable-discovery S012345678
    unselect disable-discovery S1234567890
end
```

Changing the admin password on the FortiGate for all managed FortiSwitch units

By default, each FortiSwitch has an admin account without a password. To replace the admin passwords for all FortiSwitch units managed by a FortiGate, use the following commands from the FortiGate CLI:

```
config switch-controller switch-profile
    edit default
        set login-passwd-override {enable | disable}
        set login-passwd <password>
    next
end
```

If you had already applied a profile with the override enabled and the password set and then decide to remove the admin password, you need to apply a profile with the override enabled and no password set; otherwise, your previously set password will remain in the FortiSwitch. For example:

```
config switch-controller switch-profile
  edit default
    set login-passwd-override enable
    unset login-passwd
  next
end
```

Enabling network-assisted device detection

Network-assisted device detection allows the FortiGate unit to use the information about connected devices detected by the managed FortiSwitch unit.

To enable network-assisted device detection on a VDOM:

```
config switch-controller network-monitor-settings
  set network-monitoring enable
end
```

You can display a list of detected devices from the *Device Inventory* menu in the GUI. To list the detected devices in the CLI, enter the following command:

```
diagnose user device list
```

Limiting the number of parallel process for FortiSwitch configuration

Use the following CLI commands to reduce the number of parallel process that the switch controller uses for configuring FortiSwitch units:

```
config global
  config switch-controller system
    set parallel-process-override enable
    set parallel-process <1-300>
  end
end
```

FortiSwitch features configuration

This section describes how to configure global FortiSwitch settings using FortiGate CLI commands. These settings will apply to all of the managed FortiSwitch units. You can also override some of the settings on individual FortiSwitch units.

This chapter covers the following topics:

- ["Configure VLANs" on page 1955](#)
- ["Configure IGMP settings " on page 1958](#)
- ["Configure LLDP-MED" on page 1958](#)
- ["Configure the MAC sync interval " on page 1960](#)
- ["Configure STP settings" on page 1960](#)
- ["Quarantines" on page 1961](#)

Configure VLANs

Use Virtual Local Area Networks (VLANs) to logically separate a LAN into smaller broadcast domains. VLANs allow you to define different policies for different types of users and to set finer control on the LAN traffic. (Traffic is only sent automatically within the VLAN. You must configure routing for traffic between VLANs.)

From the FortiGate unit, you can centrally configure and manage VLANs for the managed FortiSwitch units.

In FortiSwitchOS 3.3.0 and later releases, the FortiSwitch supports untagged and tagged frames in FortiLink mode. The switch supports up to 1,023 user-defined VLANs. You can assign a VLAN number (ranging from 1-4095) to each of the VLANs.

You can configure the default VLAN for each FortiSwitch port as well as a set of allowed VLANs for each FortiSwitch port.

FortiSwitch VLANs display

The *WiFi & Switch Controller > FortiSwitch VLANs* page displays VLAN information for the managed switches.

<div> + Create New Edit Delete Q Search </div>				
Name	VLAN ID	IP/Netmask	Access	Ref.
vlan44	44	192.168.2.1 255.255.255.0	SNMP	0
vlan45	45	10.10.10.1 255.255.255.0		1
vsw.port3	1	172.20.20.10 255.255.255.0	HTTPS HTTP	10

Each entry in the VLAN list displays the following information:

- *Name*—name of the VLAN
- *VLAN ID*—the VLAN number
- *IP/Netmask*—address and mask of the subnetwork that corresponds to this VLAN
- *Access*—administrative access settings for the VLAN
- *Ref*—number of configuration objects referencing this VLAN

Enabling and disabling switch-controller access VLANs through the FortiGate unit

Access VLANs are VLANs that aggregate client traffic solely to the FortiGate unit. This prevents direct client-to-client traffic visibility at the layer-2 VLAN layer. Clients can only communicate with the FortiGate unit. After the client traffic reaches the FortiGate, the FortiGate unit can then determine whether to allow various levels of access to the client by shifting the client's network VLAN as appropriate.

NOTE: IPv6 is not supported between clients within a switch-controller access VLAN.

Use `enable` to allow traffic only to and from the FortiGate and to block FortiSwitch port-to-port traffic on the specified VLAN. Use `disable` to allow normal traffic on the specified VLAN.

```
config system interface
    edit <VLAN name>
        set switch-controller-access-vlan {enable | disable}
    next
end
```

NOTE: You must configure the proxy ARP with the `config system proxy-arp` CLI command to be able to use the access VLANs. For example:

```
config system proxy-arp
  edit 1
    set interface "V100"
    set ip 1.1.1.1
    set end-ip 1.1.1.200
  next
end
```

Creating VLANs

Setting up a VLAN requires you to create the VLAN and assign FortiSwitch ports to the VLAN. You can do this with either the Web GUI or CLI.

Using the Web administration GUI

To create the VLAN:

1. Go to *WiFi & Switch Controller > FortiSwitch VLANs*, select *Create New*, and change the following settings:

Interface Name	VLAN name
VLAN ID	Enter a number (1-4094)
Color	Choose a unique color for each VLAN, for ease of visual display.
IP/Network Mask	IP address and network mask for this VLAN.

2. Enable *DHCP Server* and set the IP range.
3. Set the *Admission Control* options as required.
4. Select *OK*.

To assign FortiSwitch ports to the VLAN:

1. Go to *WiFi & Switch Controller > FortiSwitch Ports*.
2. Click the desired port row.
3. Click the *Native VLAN* column in one of the selected entries to change the native VLAN.
4. Select a VLAN from the displayed list. The new value is assigned to the selected ports.
5. Click the + icon in the *Allowed VLANs* column to change the allowed VLANs.
6. Select one or more of the VLANs (or the value *all*) from the displayed list. The new value is assigned to the selected port.

Port	Description	Native VLAN	Allowed VLANs	Device Information	PoE	Bytes (Sent/Received)
My-Switch - FS108D3W16001177 (10)						
<div>   <div>PoE Status:</div> <div>Total Budget: 75.0W</div> </div>						
port1		vsw.port3			Powered	0 B
port2		vsw.port3			Powered	0 B
port3		vlan45			Powered	0 B
port4		vlan45			Powered	0 B
port5		vlan45			Powered	0 B
port6		vsw.port3	vlan44		Powered	0 B
port7		vsw.port3	vlan44		Powered	0 B
port8		vsw.port3	vlan44		Powered	0 B
port9		vsw.port3	vlan44			0 B
port10		FGVM010000088418				33.27 MB

Using the FortiSwitch CLI

1. Create the marketing VLAN.

```
config system interface
  edit <vlan name>
    set vlanid <1-4094>
    set color <1-32>
    set interface <FortiLink-enabled interface>
  end
```

2. Set the VLAN's IP address.

```
config system interface
  edit <vlan name>
    set ip <IP address> <Network mask>
  end
```

3. Enable a DHCP Server.

```
config system dhcp server
  edit 1
    set default-gateway <IP address>
    set dns-service default
    set interface <vlan name>
    config ip-range
      set start-ip <IP address>
      set end-ip <IP address>
    end
    set netmask <Network mask>
  end
```

4. Assign ports to the VLAN.

```
config switch-controller managed-switch
  edit <Switch ID>
```

```
config ports
  edit <port name>
    set vlan <vlan name>
    set allowed-vlans <vlan name>
    or
    set allowed-vlans-all enable
  next
end
end
```

Assign untagged VLANs to a managed FortiSwitch port:

```
config switch-controller managed-switch
  edit <managed-switch>
    config ports
      edit <port>
        set untagged-vlans <VLAN-name>
      next
    end
  next
end
```

Configure IGMP settings

Use the following command to configure the global IGMP settings.

Aging time is the maximum number of seconds that the system will retain a multicast snooping entry. Enter an integer value from 15 to 3600. The default value is 300.

Flood-unknown-multicast controls whether the system will flood unknown multicast messages within the VLAN.

```
config switch-controller igmp-snooping
  set aging-time <15-3600>
  set flood-unknown-multicast {enable | disable}
end
```

Configure LLDP-MED

To configure LLDP profiles:

```
config switch-controller lldp-profile
  edit <profile number>
    set 802.1-tlvs port-vlan-id
    set 802.3-tlvs max-frame-size
    set auto-isl {enable | disable}
    set auto-isl-hello-timer <1-30>
    set auto-isl-port-group <0-9>
    set auto-isl-receive-timeout <3-90>
    set med-tlvs (inventory-management | network-policy)
  end
```

To configure LLDP settings:

```
config switch-controller lldp-settings
  set status < enable | disable >
```

```

set tx-hold <int>
set tx-interval <int>
set fast-start-interval <int>
set management-interface {internal | management}
end

```

Variable	Description
status	Enable or disable
tx-hold	Number of tx-intervals before the local LLDP data expires. Therefore, the packet TTL (in seconds) is tx-hold times tx-interval . The range for tx-hold is 1 to 16, and the default value is 4.
tx-interval	How often the FortiSwitch transmits the LLDP PDU. The range is 5 to 4095 seconds, and the default is 30 seconds.
fast-start-interval	How often the FortiSwitch transmits the first 4 LLDP packets when a link comes up. The range is 2 to 5 seconds, and the default is 2 seconds. Set this variable to zero to disable fast start.
management-interface	Primary management interface to be advertised in LLDP and CDP PDUs.

Create LLDP asset tags for each managed FortiSwitch

You can use the following commands to add an LLDP asset tag for a managed FortiSwitch:

```

config switch-controller managed-switch
edit <fsw>
set switch-device-tag <string>
end

```

Add media endpoint discovery (MED) to an LLDP configuration

You can use the following commands to add media endpoint discovery (MED) features to an LLDP profile:

```

config switch-controller lldp-profile
edit <lldp-profile>
config med-network-policy
edit guest-voice
set status {disable | enable}
next
edit guest-voice-signaling
set status {disable | enable}
next
edit guest-voice-signaling
set status {disable | enable}
next
edit softphone-voice
set status {disable | enable}
next
edit streaming-video
set status {disable | enable}
next
edit video-conferencing
set status {disable | enable}
end

```

```
    next
    edit video-signaling
        set status {disable | enable}
    next
    edit voice
        set status {disable | enable}
    next
    edit voice-signaling
        set status {disable | enable}
    end
config custom-tlvs
    edit <name>
        set oui <identifier>
        set subtype <subtype>
        set information-string <string>
    end
end
```

Display LLDP information

You can use the following commands to display LLDP information:

```
diagnose switch-controller dump lldp stats <switch> <port>
diagnose switch-controller dump lldp neighbors-summary <switch>
diagnose switch-controller dump lldp neighbors-detail <switch>
```

Configure the MAC sync interval

Use the following commands to configure the global MAC sync interval.

The MAC sync interval is the time interval between MAC synchronizations. The range is 30 to 600 seconds, and the default value is 60.

```
config switch-controller mac-sync-settings
    set mac-sync-interval <30-600>
end
```

Configure STP settings

NOTE: STP is not supported between a FortiGate unit and a FortiSwitch unit in FortiLink mode.

Use the following CLI commands for global STP configuration. This configuration applies to all managed FortiSwitch units:

```
config switch-controller stp-settings
    set name <name>
    set revision <stp revision>
    set hello-time <hello time>
    set forward-time <forwarding delay>
    set max-age <maximum aging time>
    set max-hops <maximum number of hops>
end
```

You can override the global STP settings for a FortiSwitch unit using the following commands:

```
config switch-controller managed-switch
```

```
edit <switch-id>
  config stp-settings
    set local-override enable
```

Quarantines

Administrators can use MAC addresses to quarantine hosts and users connected to a FortiSwitch unit. Quarantined MAC addresses are isolated from the rest of the network and LAN by using a separate VLAN.

Quarantining MAC addresses

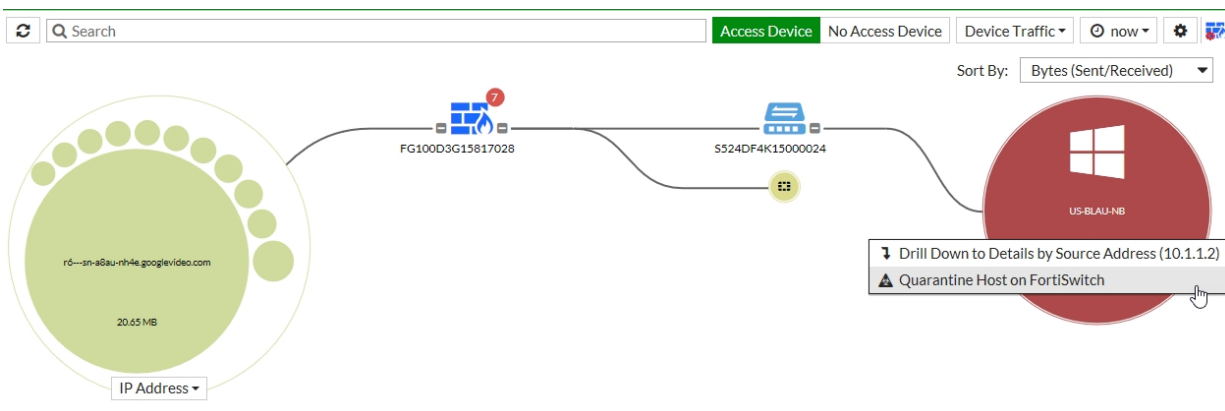

You can use the FortiGate GUI or CLI to quarantine a MAC address.

NOTE: If you have multiple FortiLink interfaces, only the first quarantine VLAN is created successfully (with an IP address of 10.254.254.254). Additional quarantine VLANs will have an empty IP address.

Using the FortiGate GUI

In the FortiGate GUI, the quarantine feature is automatically enabled when you quarantine a host.

1. Select the host to quarantine.
 - Go to *Security Fabric > Physical Topology*, right-click on a host, and select *Quarantine Host on FortiSwitch*.
 - Go to *Security Fabric > Logical Topology*, right-click on a host, and select *Quarantine Host on FortiSwitch*.
 - Go to *FortiView > Sources*, right-click on an entry in the Source column, and select *Quarantine Host on FortiSwitch*.
2. Select *Accept* to confirm that you want to quarantine the host.

Using the FortiGate CLI

NOTE: Previously, this feature used the `config switch-controller quarantine` CLI command.

By default, the quarantine feature is enabled. When you upgrade a FortiGate unit from an older to a newer firmware version, the FortiGate unit uses the quarantine feature status from the older configuration. If the quarantine feature was disabled in the older configuration, it will be disabled after the upgrade.

You can add MAC addresses to be quarantined even when the quarantine feature is disabled. The MAC addresses are only quarantined when the quarantine feature is enabled.

The table size limit for the quarantine entry is 512. There is no limit for how many MAC addresses can be quarantined per quarantine entry.

```
config user quarantine
  set quarantine enable
  config targets
    edit <quarantine_entry_name>
      set description <string>
      config macs
        edit <MAC_address_1>
        next
        edit <MAC_address_2>
        next
        edit <MAC_address_3>
        next
      end
    end
  end
```

Option	Description
quarantine_entry_name	A name for this quarantine entry.
string	Optional. A description of the MAC addresses being quarantined.
MAC_address_1, MAC_address_2, MAC_address_3	A layer-2 MAC address in the following format: 12:34:56:aa:bb:cc

For example:

```
config user quarantine
  set quarantine enable
  config targets
    edit quarantine1
      config macs
        set description "infected by virus"
        edit 00:00:00:aa:bb:cc
        next
        edit 00:11:22:33:44:55
        next
        edit 00:01:02:03:04:05
        next
      end
    end
  end
```

Viewing quarantine entries

Quarantine entries are created on the FortiGate unit that is managing the FortiSwitch unit.

Using the FortiGate GUI

1. Go to *Monitor > Quarantine Monitor*.

2. Click *Quarantined on FortiSwitch*.

The Quarantined on FortiSwitch button is only available if a device is detected behind the FortiSwitch unit, which requires Device Detection to be enabled.

Refresh	Delete	Remove All	Search	All	Quarantined on FortiSwitch	Banned IP
Type	Details	Source	Expires	Description		
MAC address	18:db:f2:32:52:e7 (US-BLAU-NB)	Administrative	Never	Hostname: US-BLAU-NB, Use...		

Using the FortiGate CLI

Use the following command to view the quarantine list of MAC addresses:

```
show user quarantine
```

For example:

```
show user quarantine

config user quarantine
  set quarantine enable
  config targets
    edit quarantine1
      config macs
        set description "infected by virus"
        edit 00:00:00:aa:bb:cc
        next
        edit 00:11:22:33:44:55
        next
        edit 00:01:02:03:04:05
        next
      end
    end
  end
end
```

When the quarantine feature is enabled on the FortiGate unit, it creates a quarantine VLAN (qtn.<FortiLink_port_name>) and a quarantine DHCP server (with the quarantine VLAN as default gateway) on the virtual domain. The quarantine VLAN is applied to the allowed and untagged VLANs on all connected FortiSwitch ports.

Use the following command to view the quarantine VLAN:

```
show system interface qtn.<FortiLink_port_name>
```

For example:

```
show system interface qtn.port7

config system interface
  edit "qtn.port7"
    set vdom "vdom1"
    set ip 10.254.254.254 255.255.255.0
    set description "Quarantine VLAN"
    set security-mode captive-portal
    set replacemsg-override-group "auth-intf-qtn.port7"
    set device-identification enable
    set device-identification-active-scan enable
    set snmp-index 34
    set switch-controller-access-vlan enable
    set color 6
```

```

        set interface "port7"
        set vlanid 4093
    next
end

```

Use the following commands to view the quarantine DHCP server:

```

show system dhcp server
config system dhcp server
    edit 2
        set dns-service default
        set default-gateway 10.254.254.254
        set netmask 255.255.255.0
        set interface "qtn.port7"
        config ip-range
            edit 1
                set start-ip 10.254.254.192
                set end-ip 10.254.254.253
            next
        end
        set timezone-option default
    next
end

```

Use the following command to view how the quarantine VLAN is applied to the allowed and untagged VLANs on all connected FortiSwitch ports:

```

show switch-controller managed-switch

```

For example:

```

show switch-controller managed-switch

config switch-controller managed-switch
    edit "FS1D483Z15000036"
        set fsw-wan1-peer "port7"
        set fsw-wan1-admin enable
        set version 1
        set dynamic-capability 503
        config ports
            edit "port1"
                set vlan "vsw.port7"
                set allowed-vlans "qtn.port7"
                set untagged-vlans "qtn.port7"
            next
            edit "port2"
                set vlan "vsw.port7"
                set allowed-vlans "qtn.port7"
                set untagged-vlans "qtn.port7"
            next
            edit "port3"
                set vlan "vsw.port7"
                set allowed-vlans "qtn.port7"
                set untagged-vlans "qtn.port7"
            next
            ...
        end
    end
end

```

Releasing MAC addresses from quarantine

Using the FortiGate GUI

1. Go to *Monitor > Quarantine Monitor*.
2. Click *Quarantined on FortiSwitch*.
3. Right-click on one of the entries and select *Delete* or *Remove All*.
4. Click *OK* to confirm your choice.

 Refresh		 Delete	 Remove All	 Search	All	Quarantined on FortiSwitch	Banned IP
▼ Type		▼ Details		▼ Source	▼ Expires	▼ Description	
MAC address		18:00:00:00:00:00 (US-BLAU-NB)		Administrative	Never	Hostname: US-BLAU-NB, Use...	
		<div><div> Delete</div><div> Remove All</div></div>					

Using the FortiGate CLI

To release MAC addresses from quarantine, you can delete a single MAC address or delete a quarantine entry, which will delete all of the MAC addresses listed in the entry. You can also disable the quarantine feature, which releases all quarantined MAC addresses from quarantine.

To delete a single quarantined MAC address:

```
config user quarantine
  config targets
    edit <quarantine_entry_name>
      config macs
        delete <MAC_address_1>
      end
    end
  end
end
```

To delete all MAC addresses in a quarantine entry:

```
config user quarantine
  config targets
    delete <quarantine_entry_name>
  end
end
```

To disable the quarantine feature:

```
config user quarantine
  set quarantine disable
end
```

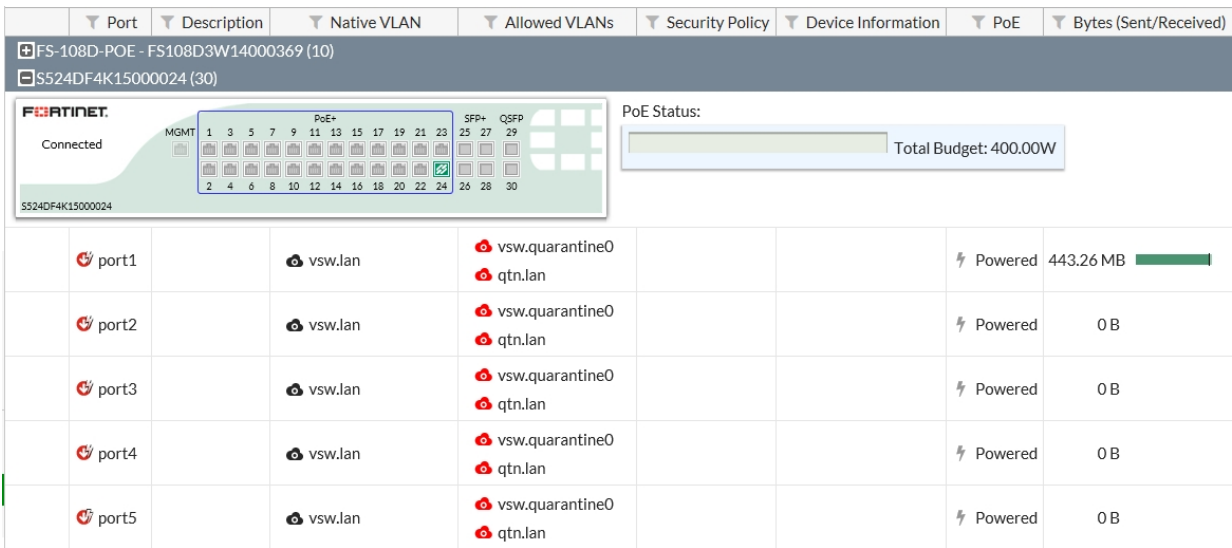

FortiSwitch port features

You can configure the FortiSwitch port feature settings from the FortiGate using the FortiSwitch CLI or web administration GUI.

FortiSwitch ports display

The *WiFi & Switch Controller > FortiSwitch Ports* page displays port information about each of the managed switches.

The following figure shows the display for a FortiSwitch 524D-FPOE:

The switch faceplate displays:

- active ports (green)
- PoE-enabled ports (blue rectangle)
- FortiLink port (link icon)

PoE Status displays the total power budget and the actual power currently allocated.

The allocated power displays a blue bar for the used power (currently being consumed) and a green bar for the reserved power (power available for additional devices on the POE ports). See the following figures:

Each entry in the port list displays the following information:

- Port status (red for down, green for up)
- Port name

- Native VLAN
- Allowed VLANs
- Device information
- PoE status
- Bytes sent and received by the port

Configuring ports using the GUI

You can use the *WiFi & Switch Controller > FortiSwitch Ports* page to do the following with FortiSwitch switch ports:

- Set the native VLAN and add more VLANs
- Edit the description of the port
- Enable or disable the port
- Enable or disable PoE for the port
- Enable or disable DHCP blocking (if supported by the port)
- Enable or disable IGMP snooping (if supported by the port)
- Enable or disable whether a port is an edge port
- Enable or disable STP (if supported by the port)
- Enable or disable loop guard (if supported by the port)
- Enable or disable STP BPDU guard (if supported by the port)
- Enable or disable STP root guard (if supported by the port)

Resetting PoE-enabled ports

If you need to reset PoE-enabled ports, go to *WiFi & Switch Control > FortiSwitch Ports*, right-click on one or more PoE-enabled ports and select *Reset PoE* from the context menu.

You can also go to *WiFi & Switch Control > Managed FortiSwitch* and click on a port icon for the FortiSwitch of interest. In the FortiSwitch Ports page, right-click on one or more PoE-enabled ports and select *Reset PoE* from the context menu.

Configuring ports using the FortiGate CLI

You can configure the following FortiSwitch port settings using the FortiGate CLI:

- [Configuring port speed and status on page 1968](#)
- [Configure a VLAN on the port \(see \[Configure VLANs\]\(#\)\)](#)
- [Sharing FortiSwitch ports between VDOMs on page 1968](#)
- [Limiting the number of learned MAC addresses on a FortiSwitch interface on page 1970](#)
- [Configuring the DHCP trust setting on page 1972](#)
- [Configuring PoE on page 1973](#)
- [Configuring edge ports on page 1974](#)
- [Configuring STP on page 1974](#)
- [Configuring STP root guard on page 1975](#)
- [Configuring STP BPDU guard on page 1976](#)
- [Configuring loop guard on page 1978](#)

- [Configuring LLDP settings on page 1978](#)
- [Configuring IGMP settings on page 1979](#)
- [Configuring sFlow on page 1979](#)
- [Configuring Dynamic ARP inspection \(DAI\) on page 1980](#)
- [Configuring FortiSwitch port mirroring on page 1981](#)

Configuring port speed and status

Use the following commands to set port speed and other base port settings:

```
config switch-controller managed-switch
edit <switch>
config ports
edit <port>
set description <text>
set speed <speed>
set status {down | up}
end
end
```

For example:

```
config switch-controller managed-switch
edit S524DF4K15000024
config ports
edit port1
set description "First port"
set speed auto
set status up
end
end
```

Sharing FortiSwitch ports between VDOMs

Virtual domains (VDOMs) are a method of dividing a FortiGate unit into two or more virtual units that function as multiple independent units. VDOMs provide separate security domains that allow separate zones, user authentication, security policies, routing, and VPN configurations.

FortiSwitch ports can now be shared between VDOMs.

NOTE: You cannot use the quarantine feature while sharing FortiSwitch ports between VDOMs.

To share FortiSwitch ports between VDOMs:

1. Create one or more VDOMs.
2. Assign VLANs to each VDOM as required.
3. From these VLANs, select one VLAN to be the default VLAN for the ports in the virtual switch:

```
config switch-controller global
set default-virtual-switch-vlan <VLAN>
```

NOTE: You must execute these commands from the VDOM that the default VLAN belongs to.

When you add a new port to the VDOM, the new port will be automatically assigned to the default VLAN. You can reassign the ports to other VLANs later.

4. Create a virtual port pool (VPP) to contain the ports to be shared:

```
config switch-controller virtual-port-pool
  edit <VPP_name>
    description <string>
  next
end
```

NOTE: You must execute these commands from the VDOM that the default VLAN belongs to.

For example:

```
config switch-controller virtual-port-pool
  edit "pool3"
    description "pool for port3"
  next
end
```

5. Share a FortiSwitch port from the VDOM that the FortiSwitch belongs to with another VDOM or export the FortiSwitch port to a VPP where it can be used by any VDOM:

```
config switch-controller managed-switch
  edit <switch.id>
    config ports
      edit <port_name>
        set {export-to-pool <VPP_name> | export-to <VDOM_name>}
        set export-tags <string1,string2,string3,...>
      next
    end
  next
end
```

NOTE: You must execute these commands from the VDOM that the default VLAN belongs to.

For example, if you want to export a port to the VPP named `pool3`:

```
config switch-controller managed-switch
  edit "S524DF4K15000024"
    config ports
      edit port3
        set export-to-pool "pool3"
        set export-tags "Pool 3"
      next
    end
  next
end
```

For example, if you want to export a port to the VDOM named `vdom3`:

```
config switch-controller managed-switch
  edit "S524DF4K15000024"
    config ports
      edit port3
        set export-to "vdom3"
        set export-tags "VDOM 3"
```

```

        next
    end
next
end

```

6. Request a port in a VPP:

```
execute switch-controller virtual-port-pool request <FortiSwitch_device_ID> <port_name>
```

NOTE: You must execute this command from the VDOM that is requesting the port.

For example:

```
execute switch-controller virtual-port-pool request S524DF4K15000024h port3
```

7. Return a port to a VPP:

```
execute switch-controller virtual-port-pool return <FortiSwitch_device_ID> <port_name>
```

NOTE: You must execute this command from the VDOM that owns the port.

For example:

```
execute switch-controller virtual-port-pool return S524DF4K15000024h port3
```

You can create your own export tags using the following CLI commands:

```

config switch-controller switch-interface-tag
    edit <tag_name>
end

```

Use the following CLI command to list the contents of a specific VPP:

```
execute switch-controller virtual-port-pool show-by-pool <VPP_name>
```

Use the following CLI command to list all VPPs and their contents:

```
execute switch-controller virtual-port-pool show
```

NOTE: Shared ports do not support the following features:

- LLDP
- 802.1x
- STP
- BPDU guard
- Root guard
- DHCP snooping
- IGMP snooping
- QoS
- Port security
- MCLAG

Limiting the number of learned MAC addresses on a FortiSwitch interface

You can limit the number of MAC addresses learned on a FortiSwitch interface (port or VLAN). The limit ranges from 1 to 128. If the limit is set to the default value zero, there is no learning limit.

NOTE: Static MAC addresses are not counted in the limit. The limit refers only to learned MAC addresses.

Use the following CLI commands to limit MAC address learning on a VLAN:

```
config switch vlan
  edit <integer>
    set switch-controller-learning-limit <limit>
  end
end
```

For example:

```
config switch vlan
  edit 100
    set switch-controller-learning-limit 20
  end
end
```

Use the following CLI commands to limit MAC address learning on a port:

```
config switch-controller managed-switch
  edit <FortiSwitch_Serial_Number>
    config ports
      edit <port>
        set learning-limit <limit>
      next
    end
  end
end
```

For example:

```
config switch-controller managed-switch
  edit S524DF4K15000024
    config ports
      edit port3
        set learning-limit 50
      next
    end
  end
end
```

You can change how long learned MAC addresses are stored. By default, each learned MAC address is aged out after 300 seconds. After this amount of time, the inactive MAC address is deleted from the FortiSwitch hardware. The value ranges from 10 to 1000,000 seconds. Set the value to 0 to disable MAC address aging.

```
config switch-controller global
  set mac-aging-interval <10 to 1000000>
end
```

For example:

```
config switch-controller global
  set mac-aging-interval 500
end
```

If you want to see the first MAC address that exceeded the learning limit for an interface or VLAN, you can enable the learning-limit violation log for a managed FortiSwitch unit. Only one violation is recorded per interface or VLAN.

By default, logging is disabled. The most recent violation that occurred on each interface or VLAN is recorded in the system log. After that, no more violations are logged until the log is reset for the triggered interface or VLAN. Only the most recent 128 violations are displayed in the console.

Use the following commands to control the learning-limit violation log and to control how long learned MAC addresses are save:

```
config switch-controller global
    set mac-violation-timer <0-1500>
    set log-mac-limit-violations {enable | disable}
end
```

For example:

```
config switch-controller global
    set mac-violation-timer 1000
    set log-mac-limit-violations enable
end
```

To view the content of the learning-limit violation log for a managed FortiSwitch unit, use one of the following commands:

- `diagnose switch-controller dump mac-limit-violations all <FortiSwitch_serial_number>`
- `diagnose switch-controller dump mac-limit-violations interface <FortiSwitch_serial_number> <port_name>`
- `diagnose switch-controller dump mac-limit-violations vlan <FortiSwitch_serial_number> <VLAN_ID>`

For example, to set the learning-limit violation log for VLAN 5 on a managed FortiSwitch unit:

```
diagnose switch-controller dump mac-limit-violations vlan S124DP3XS12345678 5
```

To reset the learning-limit violation log for a managed FortiSwitch unit, use one of the following commands:

- `execute switch-controller mac-limit-violation reset all <FortiSwitch_serial_number>`
- `execute switch-controller mac-limit-violation reset vlan <FortiSwitch_serial_number> <VLAN_ID>`
- `execute switch-controller mac-limit-violation reset interface <FortiSwitch_serial_number> <port_name>`

For example, to clear the learning-limit violation log for port 5 of a managed FortiSwitch unit:

```
execute switch-controller mac-limit-violation reset interface S124DP3XS12345678 port5
```

Configuring the DHCP trust setting

The DHCP blocking feature monitors the DHCP traffic from untrusted sources (for example, typically host ports and unknown DHCP servers) that might initiate traffic attacks or other hostile actions. To prevent this, DHCP blocking filters messages on untrusted ports.

Set the port as a trusted or untrusted DHCP-snooping interface:

```
config switch-controller managed-switch
  edit <switch-id>
    config ports
      edit <port name>
        set dhcp-snooping {trusted | untrusted}
      end
    end
  end
```

For example:

```
config switch-controller managed-switch
  edit S524DF4K15000024
    config ports
      edit port1
        set dhcp-snooping trusted
      end
    end
  end
```

Configuring PoE

The following PoE CLI commands are available starting in FortiSwitchOS 3.3.0.

Enable PoE on the port

```
config switch-controller managed-switch
  edit <switch-id>
    config ports
      edit <port name>
        set poe-status {enable | disable}
      end
    end
  end
```

For example:

```
config switch-controller managed-switch
  edit S524DF4K15000024
    config ports
      edit port1
        set poe-status enable
      end
    end
  end
```

Reset the PoE port

Power over Ethernet (PoE) describes any system that passes electric power along with data on twisted pair Ethernet cabling. Doing this allows a single cable to provide both data connection and electric power to devices (for example, wireless access points, IP cameras, and VoIP phones).

The following command resets PoE on the port:

```
execute switch-controller poe-reset <fortiswitch-id> <port>
```

Display general PoE status

```
get switch-controller <fortiswitch-id> <port>
```

The following example displays the PoE status for port 6 on the specified switch:

```
# get switch-controller poe FS108D3W14000967 port6
Port(6) Power:3.90W, Power-Status: Delivering Power
Power-Up Mode: Normal Mode
Remote Power Device Type: IEEE802.3AT PD
Power Class: 4
Defined Max Power: 30.0W, Priority:3
Voltage: 54.00V
Current: 78mA
```

Configuring edge ports

Use the following commands to enable or disable an interface as an edge port:

```
config switch-controller managed-switch
edit <switch>
config ports
edit <port>
set edge-port {enable | disable}
end
end
```

For example:

```
config switch-controller managed-switch
edit S524DF4K15000024
config ports
edit port1
set edge-port enable
end
end
```

Configuring STP

Starting with FortiSwitch Release 3.4.2, STP is enabled by default for the non-FortiLink ports on the managed FortiSwitch units. STP is a link-management protocol that ensures a loop-free layer-2 network topology.

NOTE: STP is not supported between a FortiGate unit and a FortiSwitch unit in FortiLink mode.

To configure global STP settings, see [Configure STP settings on page 1960](#).

Use the following commands to enable or disable STP on FortiSwitch ports:

```
config switch-controller managed-switch
edit <switch-id>
config ports
edit <port name>
set stp-state {enabled | disabled}
end
end
```

For example:

```
config switch-controller managed-switch
edit S524DF4K15000024
config ports
edit port1
set stp-state enabled
```

```

end
end

```

To check the STP configuration on a FortiSwitch, use the following command:

```
diagnose switch-controller dump stp <FortiSwitch_serial_number> <instance_number>
```

For example:

```
FG100D3G15817028 # diagnose switch-controller dump stp S524DF4K15000024 0
```

```

Configuring STP root guard

Root guard protects the interface on which it is enabled from becoming the path to root. When enabled on an interface, superior BPDUs received on that interface are ignored or dropped. Without using root guard, any switch

that participates in STP maintains the ability to reroute the path to root. Rerouting might cause your network to transmit large amounts of traffic across suboptimal links or allow a malicious or misconfigured device to pose a security risk by passing core traffic through an insecure device for packet capture or inspection. By enabling root guard on multiple interfaces, you can create a perimeter around your existing paths to root to enforce the specified network topology.

Enable root guard on all ports that should not be root bridges. Do not enable root guard on the root port. You must have STP enabled to be able to use root guard.

Use the following commands to enable or disable STP root guard on FortiSwitch ports:

```
config switch-controller managed-switch
  edit <switch-id>
    config ports
      edit <port name>
        set stp-root-guard {enabled | disabled}
      end
    end
  end
```

For example:

```
config switch-controller managed-switch
  edit S524DF4K15000024
    config ports
      edit port1
        set stp-root-guard enabled
      end
    end
  end
```

Configuring STP BPDU guard

Similar to root guard, BPDU guard protects the designed network topology. When BPDU guard is enabled on STP edge ports, any BPDUs received cause the ports to go down for a specified number of minutes. The BPDUs are not forwarded, and the network edge is enforced.

There are two prerequisites for using BPDU guard:

- You must define the port as an edge port with the `set edge-port enable` command.
- You must enable STP on the switch interface with the `set stp-state enabled` command.

You can set how long the port will go down when a BPDU is received for a maximum of 120 minutes. The default port timeout is 5 minutes. If you set the timeout value to 0, the port will not go down when a BPDU is received, but you will have manually reset the port.

Use the following commands to enable or disable STP BPDU guard on FortiSwitch ports:

```
config switch-controller managed-switch
  edit <switch-id>
    config ports
      edit <port name>
        set stp-bpdu-guard {enabled | disabled}
        set stp-bpdu-guard-time <0-120>
      end
    end
  end
```

For example:

```
config switch-controller managed-switch
```

```

edit S524DF4K15000024
  config ports
    edit port1
      set stp-bpdu-guard enabled
      set stp-bpdu-guard-time 10
    end
  end
end

```

To check the configuration of STP BPDU guard on a FortiSwitch unit, use the following command:

```
diagnose switch-controller dump bpdu-guard-status <FortiSwitch_serial_number>
```

For example:

```

FG100D3G15817028 # diagnose switch-controller dump bpdu-guard-status
S524DF4K15000024
Managed Switch : S524DF4K15000024 0

```

Portname	State	Status	Timeout (m)	Count	Last-Event

Configuring loop guard

A loop in a layer-2 network results in broadcast storms that have far-reaching and unwanted effects. Fortinet loop guard helps to prevent loops. When loop guard is enabled on a switch port, the port monitors its subtending network for any downstream loops. The loop guard feature is designed to work in concert with STP rather than as a replacement for STP. By default, loop guard is disabled on all ports.

Use the following commands to configure loop guard on a FortiSwitch port:

```
config switch-controller managed-switch
  edit <switch-id>
    config ports
      edit <port name>
        set loop-guard {enabled | disabled}
        set loop-guard-timeout <0-120 minutes>
      end
    end
  end
```

For example:

```
config switch-controller managed-switch
  edit S524DF4K15000024
    config ports
      edit port1
        set loop-guard enabled
        set loop-guard-timeout 10
      end
    end
  end
```

Configuring LLDP settings

The Fortinet data center switches support the Link Layer Discovery Protocol (LLDP) for transmission and reception wherein the switch will multicast LLDP packets to advertise its identity and capabilities. A switch receives the equivalent information from adjacent layer-2 peers.

Use the following commands to configure LLDP on a FortiSwitch port:

```
config switch-controller managed-switch
  edit <switch-id>
    config ports
      edit <port name>
        set lldp-status {rx-only | tx-only | tx-rx | disable}
        set lldp-profile <profile name>
      end
    end
  end
```

For example:

```
config switch-controller managed-switch
  edit S524DF4K15000024
    config ports
      edit port2
        set lldp-status tx-rx
        set lldp-profile default
      end
    end
  end
```

Configuring IGMP settings

IGMP snooping allows the FortiSwitch to passively listen to the Internet Group Management Protocol (IGMP) network traffic between hosts and routers. The switch uses this information to determine which ports are interested in receiving each multicast feed. FortiSwitch can reduce unnecessary multicast traffic on the LAN by pruning multicast traffic from links that do not contain a multicast listener.

Use the following commands to configure IGMP settings on a FortiSwitch port:

```
config switch-controller managed-switch
  edit <switch-id>
    config ports
      edit <port name>
        set igmp-snooping {enable | disable}
        set igmps-flood-reports {enable | disable}
      end
    end
  end
```

For example:

```
config switch-controller managed-switch
  edit S524DF4K15000024
    config ports
      edit port3
        set igmp-snooping enable
        set igmps-flood-reports enable
      end
    end
  end
```

Configuring sFlow

sFlow is a method of monitoring the traffic on your network to identify areas on the network that might impact performance and throughput. With sFlow, you can export truncated packets and interface counters. FortiSwitch implements sFlow version 5 and supports trunks and VLANs.

NOTE: Because sFlow is CPU intensive, Fortinet does not recommend high rates of sampling for long periods.

sFlow uses packet sampling to monitor network traffic. The sFlow agent captures packet information at defined intervals and sends them to an sFlow collector for analysis, providing real-time data analysis. To minimize the impact on network throughput, the information sent is only a sampling of the data.

The sFlow collector is a central server running software that analyzes and reports on network traffic. The sampled packets and counter information, referred to as flow samples and counter samples, respectively, are sent as sFlow datagrams to a collector. Upon receiving the datagrams, the sFlow collector provides real-time analysis and graphing to indicate the source of potential traffic issues. sFlow collector software is available from a number of third-party software vendors. You must configure a FortiGate policy to transmit the samples from the FortiSwitch unit to the sFlow collector.

sFlow can monitor network traffic in two ways:

- Flow samples—You specify the percentage of packets (one out of n packets) to randomly sample.
- Counter samples—You specify how often (in seconds) the network device sends interface counters.

Use the following CLI commands to specify the IP address and port for the sFlow collector. By default, the IP address is 0.0.0.0, and the port number is 6343.

```
config switch-controller sflow
  collector-ip <x.x.x.x>
```

```

    collector-port <port_number>
end

```

Use the following CLI commands to configure sFlow:

```

config switch-controller managed-switch <FortiSwitch_serial_number>
    config ports
        edit <port_name>
            set sflow-sampler <disabled | enabled>
            set sflow-sample-rate <0-99999>
            set sflow-counter-interval <1-255>
        next
    next
end

```

For example:

```

config switch-controller sflow
    collector-ip 1.2.3.4
    collector-port 10
end

config switch-controller managed-switch S524DF4K15000024
    config ports
        edit port5
            set sflow-sampler enabled
            set sflow-sample-rate 10
            set sflow-counter-interval 60
        next
    next
end

```

Configuring Dynamic ARP inspection (DAI)

DAI prevents man-in-the-middle attacks and IP address spoofing by checking that packets from untrusted ports have valid IP-MAC-address binding. DAI allows only valid ARP requests and responses to be forwarded.

To use DAI, you must first enable the DHCP-snooping feature, enable DAI, and then enable DAI for each VLAN. By default, DAI is disabled on all VLANs.

After enabling DHCP snooping with the `set switch-controller-dhcp-snooping enable` command, use the following CLI commands to enable DAI and then enable DAI for a VLAN:

```

config system interface
    edit vsw.test
        set switch-controller-arp-inspection <enable | disable>
    end

config switch-controller managed-switch
    edit <sn>
        config ports
            edit <VLAN_ID>
                arp-inspection-trust <untrusted | trusted>
            next
        end
    next
end

```

Use the following CLI command to check DAI statistics for a FortiSwitch unit:

```
diagnose switch arp-inspection stats <FortiSwitch_Serial_Number>
```

Use the following CLI command to delete DAI statistics for a specific VLAN:

```
diagnose switch arp-inspection stats clear <VLAN_ID> <FortiSwitch_Serial_Number>
```

Configuring FortiSwitch port mirroring

The FortiSwitch unit can send a copy of any ingress or egress packet on a port to egress on another port of the same FortiSwitch unit. The original traffic is unaffected. This process is known as port mirroring and is typically used for external analysis and capture.

Use the following CLI commands to configure FortiSwitch port mirroring:

```
config switch-controller managed-switch
  edit <FortiSwitch_Serial_Number>
    config mirror
      edit <mirror_name>
        set status <active | inactive>
        set dst <port_name>
        set switching-packet <enable | disable>
        set src-ingress <port_name>
        set src-egress <port_name>
      next
    end
  next
```

NOTE: The `set status` and `set dst` commands are mandatory for port mirroring.

For example:

```
config switch-controller managed-switch
  edit S524DF4K15000024
    config mirror
      edit 2
        set status active
        set dst port1
        set switching-packet enable
        set src-ingress port2 port3
        set src-egress port4 port5
      next
    end
  next
```

FortiSwitch port security policy

To control network access, the managed FortiSwitch unit supports IEEE 802.1x authentication. A supplicant connected to a port on the switch must be authenticated by a RADIUS/Diameter server to gain access to the network. The supplicant and the authentication server communicate using the switch using the EAP protocol. The managed FortiSwitch unit supports EAP-PEAP, EAP-TTLS, EAP-TLS, and EAP-MD5.

To use the RADIUS server for authentication, you must configure the server before configuring the users or user groups on the managed FortiSwitch unit.

NOTE: In FortiLink mode, you must manually create a firewall policy to allow RADIUS traffic for 802.1x authentication from the FortiSwitch unit (for example, from the FortiLink interface) to the RADIUS server through the FortiGate.

The managed FortiSwitch unit implements MAC-based authentication. The switch saves the MAC address of each supplicant's device. The switch provides network access only to devices that have successfully been authenticated.

You can enable the MAC Authentication Bypass (MAB) option for devices (such as network printers) that cannot respond to the 802.1x authentication request. With MAB enabled on the port, the system will use the device MAC address as the user name and password for authentication.

Optionally, you can configure a guest VLAN for unauthorized users. Alternatively, you can specify a VLAN for users whose authentication was unsuccessful.

When you are testing your system configuration for 802.1x authentication, you can use the monitor mode to allow network traffic to flow, even if there are configuration problems or authentication failures.

This chapter covers the following topics:

- ["Configure the 802.1X settings for a virtual domain" on page 1982](#)
- ["Override the virtual domain settings" on page 1983](#)
- ["Define an 802.1X security policy" on page 1983](#)
- ["Apply an 802.1X security policy to a FortiSwitch port" on page 1985](#)
- ["Test 802.1x authentication with monitor mode" on page 1985](#)
- ["Restrict the type of frames allowed through IEEE 802.1Q ports" on page 1986](#)
- ["RADIUS accounting support" on page 1986](#)

Configure the 802.1X settings for a virtual domain

To configure the 802.1X security policy for a virtual domain, use the following commands:

```
config switch-controller 802-1X-settings
    set reauth-period < int >
    set max-reauth-attempt < int >
    set link-down-auth < *set-unauth | no-action >
end
```

Option	Description
<code>set link-down-auth</code>	If a link is down, this command determines the authentication state. Choosing <code>set-auth</code> sets the interface to unauthenticated when a link is down, and reauthentication is needed. Choosing <code>no-auth</code> means that the interface does not need to be reauthenticated when a link is down.
<code>set reauth-period</code>	This command sets how often reauthentication is needed. The range is 1-1440 minutes. The default is 60 minutes. Setting the value to 0 minutes disables reauthentication.

Option	Description
<code>set max-reauth-attempt</code>	This command sets the maximum number of reauthentication attempts. The range is 1-15. the default is 3. Setting the value to 0 disables reauthentication.

Override the virtual domain settings

You can override the virtual domain settings for the 802.1X security policy.

Using the FortiGate GUI

To override the 802.1X settings for a virtual domain:

1. Go to *WiFi & Switch Controller > Managed FortiSwitch*.
2. Click on a FortiSwitch faceplate and select *Edit*.
3. In the Edit Managed FortiSwitch page, move the *Override 802-1X settings* slider to the right.
4. In the Reauthentication Interval field, enter the number of minutes before reauthentication is required. The maximum interval is 1,440 minutes. Setting the value to 0 minutes disables reauthentication.
5. In the Max Reauthentication Attempts field, enter the maximum times that reauthentication is attempted. The maximum number of attempts is 15. Setting the value to 0 disables reauthentication.
6. Select *Deauthenticate* or *None* for the link down action. Selecting *Deauthenticate* sets the interface to unauthenticated when a link is down, and reauthentication is needed. Selecting *None* means that the interface does not need to be reauthenticated when a link is down.
7. Select *OK*.

Using the FortiGate CLI

To override the 802.1X settings for a virtual domain, use the following commands:

```
config switch-controller managed-switch
  edit < switch >
    config 802-1X-settings
      set local-override [ enable | *disable ]
      set reauth-period < int >                // visible if override enabled
      set max-reauth-attempt < int >           // visible if override enabled
      set link-down-auth < *set-unauth | no-action > // visible if override enabled
    end
  next
end
```

For a description of the options, see [Configure the 802.1X settings for a virtual domain](#).

Define an 802.1X security policy

You can define multiple 802.1X security policies.

Using the FortiGate GUI

To create an 802.1X security policy:

1. Go to *WiFi & Switch Controller > FortiSwitch Security Policies*.
2. Select *Create New*.
3. Enter a name for the new FortiSwitch security policy.
4. For the security mode, select *Port-based* or *MAC-based*.
5. Select + to select which user groups will have access.
6. Enable or disable guest VLANs on this interface to allow restricted access for some users.
7. Enter the number of seconds for authentication delay for guest VLANs. The range is 1-900 seconds.
8. Enable or disable authentication fail VLAN on this interface to allow restricted access for users who fail to access the guest VLAN.
9. Enable or disable MAC authentication bypass (MAB) on this interface.
10. Enable or disable EAP pass-through mode on this interface.
11. Enable or disable whether the session timeout for the RADIUS server will overwrite the local timeout.
12. Select *OK*.

Using the FortiGate CLI

To create an 802.1X security policy, use the following commands:

```
config switch-controller security-policy 802-1X
edit "<policy.name>"
    set security-mode {802.1X | 802.1X-mac-based}
    set user-group <*group_name | Guest-group | SSO_Guest_Users>
    set mac-auth-bypass [enable | *disable]
    set eap-passthru [enable | disable]
    set guest-vlan [enable | *disable]
    set guest-vlan-id "guest-VLAN-name"
    set guest-auth-delay <integer>
    set auth-fail-vlan [enable | *disable]
    set auth-fail-vlan-id "auth-fail-VLAN-name"
    set radius-timeout-overwrite [enable | *disable]
    set policy-type 802.1X
end
end
```

Option	Description
<code>set security-mode</code>	You can restrict access with 802.1X port-based authentication or with 802.1X MAC-based authentication.
<code>set user-group</code>	You can set a specific group name, Guest-group, or SSO_Guest_Users to have access. This setting is mandatory.
<code>set mac-auth-bypass</code>	You can enable or disable MAB on this interface.
<code>set eap-passthrough</code>	You can enable or disable EAP pass-through mode on this interface.
<code>set guest-vlan</code>	You can enable or disable guest VLANs on this interface to allow restricted access for some users.

Option	Description
<code>set guest-vlan-id "guest-VLAN-name"</code>	You can specify the name of the guest VLAN.
<code>set guest-auth-delay</code>	You can set the authentication delay for guest VLANs on this interface. The range is 1-900 seconds.
<code>set auth-fail-vlan</code>	You can enable or disable authentication fail VLAN on this interface to allow restricted access for users who fail to access the guest VLAN.
<code>set auth-fail-vlan-id "auth-fail-VLAN-name"</code>	You can specify the name of the authentication fail VLAN
<code>set radius-timeout-overwrite</code>	You can enable or disable whether the session timeout for the RADIUS server will overwrite the local timeout.
<code>set policy-type 802.1X</code>	You can set the policy type to the 802.1X security policy.

Apply an 802.1X security policy to a FortiSwitch port

You can apply a different 802.1X security policy to each FortiSwitch port.

Using the FortiGate GUI

To apply an 802.1X security policy to a managed FortiSwitch port:

1. Go to *WiFi & Switch Controller > FortiSwitch Ports*.
2. Select the + next to a FortiSwitch unit.
3. In the Security Policy column for a port, click + to select a security policy.
4. Select *OK* to apply the security policy to that port.

Using the FortiGate CLI

To apply an 802.1X security policy to a managed FortiSwitch port, use the following commands:

```
config switch-controller managed-switch
  edit <managed-switch>
    config ports
      edit <port>
        set port-security-policy <802.1X-policy>
      next
    end
  next
end
```

Test 802.1x authentication with monitor mode

Use the monitor mode to test your system configuration for 802.1x authentication. You can use monitor mode to test port-based authentication, MAC-based authentication, EAP pass-through mode, and MAC authentication

bypass. Monitor mode is disabled by default. After you enable monitor mode, the network traffic will continue to flow, even if the users fail authentication.

To enable or disable monitor mode, use the following commands:

```
config switch-controller security-policy 802-1X
  edit "<policy_name>"
    set open-auth {enable | disable}
  next
end
```

Restrict the type of frames allowed through IEEE 802.1Q ports

You can now specify whether each FortiSwitch port discards tagged 802.1Q frames or untagged 802.1Q frames or allows all frames access to the port. By default, all frames have access to each FortiSwitch port.

Use the following CLI commands:

```
config switch-controller managed-switch <SN>
  config ports
    edit <port_name>
      set discard-mode <none | all-tagged | all-untagged>
    next
  next
end
```

RADIUS accounting support

The FortiSwitch unit uses 802.1x-authenticated ports to send five types of RADIUS accounting messages to the RADIUS accounting server to support FortiGate RADIUS single sign-on:

- **START**—The FortiSwitch has been successfully authenticated, and the session has started.
- **STOP**—The FortiSwitch session has ended.
- **INTERIM**—Periodic messages sent based on the value set using the `set acct-interim-interval` command.
- **ON**—FortiSwitch will send this message when the switch is turned on.
- **OFF**—FortiSwitch will send this message when the switch is shut down.

Use the following commands to set up RADIUS accounting so that FortiOS can send accounting messages to managed FortiSwitch units:

```
config user radius
  edit <RADIUS_server_name>
    set acct-interim-interval <seconds>
    config accounting-server
      edit <entry_ID>
        set status {enable | disable}
        set server <server_IP_address>
        set secret <secret_key>
        set port <port_number>
      next
    end
  next
end
```

Additional capabilities

This chapter covers the following topics:

- [Execute custom FortiSwitch commands on page 1987](#)
- [View and upgrade the FortiSwitch firmware version on page 1988](#)
- [FortiSwitch log export on page 1989](#)
- [FortiSwitch per-port device visibility on page 1989](#)
- [FortiGate CLI support for FortiSwitch features \(on non-FortiLink ports\) on page 1989](#)
- [Synchronizing the FortiGate unit with the managed FortiSwitch units on page 1994](#)
- [Replacing a managed FortiSwitch unit on page 1995](#)

Execute custom FortiSwitch commands

From the FortiGate, you can execute FortiSwitch commands on the managed FortiSwitch.

This feature adds a simple scripting mechanism for users to execute generic commands on the switch.

NOTE: FortiOS 5.6.0 introduces additional capabilities related to the managed FortiSwitch.

Create a command

Use the following syntax to create a command file:

```
config switch-controller custom-command
  edit <cmd-name>
    set command " <FortiSwitch commands>"
```

Next, create a command file to set the STP max-age parameter:

```
config switch-controller custom-command
  edit "stp-age-10"
    set command "config switch stp setting
      set max-age 10
    end
  "
next
end
```

Execute a command

After you have created a command file, use the following command on the FortiGate to execute the command file on the target switch:

```
exec switch-controller custom-command <cmd-name> <target-switch>
```

The following example runs the **stp-age-10** command on the specified target FortiSwitch:

```
# exec switch-controller custom-command stp-age-10 S124DP3X15000118
```

View and upgrade the FortiSwitch firmware version

You can view the current firmware version of a FortiSwitch and upgrade the FortiSwitch to a new firmware version. FortiGate will suggest an upgrade when a new version is available in FortiGuard.

Using the FortiGate Web interface

To view the FortiSwitch firmware version:

1. Go to **WiFi & Switch Controller>Managed FortiSwitch**.
2. In the main panel, select the FortiSwitch faceplate and click **Edit**.
3. In the **Edit Managed FortiSwitch** panel, the **Firmware** section displays the current build on the FortiSwitch.

To upgrade the firmware on multiple FortiSwitch units at the same time:

1. Go to *WiFi & Switch Controller > Managed FortiSwitch*.
2. Select the faceplates of the FortiSwitch units that you want to upgrade.
3. Click *Upgrade*.
The *Upgrade FortiSwitches* page opens.
4. Select *FortiGuard* or select *Upload* and then select the firmware file to upload.
If you select *FortiGuard*, all FortiSwitch units that can be upgraded are upgraded. If you select *Upload*, only one firmware image can be used at a time for upgrading.
5. Select *Upgrade*.

Using the CLI

Use the following command to display the latest version:

```
diagnose fdsm fortisw-latest-ver <model>
```

Use the following command to download the image:

```
diagnose fdsm fortisw-download <image id>
```

The following example shows how to download the latest image for FS224D:

```
FG100D3G15801204 (global) # diagnose fdsm fortisw-latest-ver FS224D
FS224D - 3.4.2 b192 03004000FIMG0900904002FG100D3G15801204 (global) #

diagnose fdsm fortisw-download 03004000FIMG0900904002

Download image-03004000FIMG0900904002:
#####
Result=Success
```

Use the following CLI commands to enable the use of HTTPS to download firmware to managed FortiSwitch units:

```
config switch-controller global
  set https-image-push enable
end
```

From your FortiGate CLI, you can upgrade the firmware of all of the managed FortiSwitch units of the same model using a single `execute` command. The command includes the name of a firmware image file and all of the managed FortiSwitch units compatible with that firmware image file are upgraded. For example:

```
execute switch-controller stage-tiered-swtp-image ALL <firmware-image-file>
```

You can also use the following command to restart all of the managed FortiSwitch units after a 2-minute delay.

```
execute switch-controller restart-swtp-delayed ALL
```

FortiSwitch log export

You can enable and disable the managed FortiSwitch units to export their syslogs to the FortiGate. The setting is global, and the default setting is enabled. Starting in FortiOS 5.6.3, more details are included in the exported FortiSwitch logs.

To allow a level of filtering, FortiGate sets the user field to "fortiswitch-syslog" for each entry.

The following is the CLI command syntax:

```
config switch-controller switch-log
  set status (*enable | disable)
  set severity [emergency | alert | critical | error | warning | notification |
    *information | debug]
end
```

You can override the global log settings for a FortiSwitch, using the following commands:

```
config switch-controller managed-switch
  edit <switch-id>
    config switch-log
      set local-override enable
```

At this point, you can configure the log settings that apply to this specific switch.

FortiSwitch per-port device visibility

In the FortiGate GUI, **User & Device > Device List** displays a list of devices attached to the FortiSwitch ports. For each device, the table displays the IP address of the device and the interface (FortiSwitch name and port).

From the CLI, the following command displays information about the host devices:

```
diagnose switch-controller dump mac-hosts_switch-ports
```

FortiGate CLI support for FortiSwitch features (on non-FortiLink ports)

You can configure the following FortiSwitch features from the FortiGate CLI.

Configuring a link aggregation group (LAG)

You can configure a link aggregation group (LAG) for non-FortiLink ports on a FortiSwitch. You cannot configure ports from different FortiSwitch units in one LAG.

```
config switch-controller managed-switch
  edit <switch-id>
    config ports
      it <trunk name>
```

```

        set type trunk
        set mode < static | lacp > Link Aggregation mode
        set bundle (enable | disable)
        set min-bundle <int>
        set max-bundle <int>
        set members < port1 port2 ...>
    next
end
end
end
end

```

Configuring an MCLAG with managed FortiSwitch units

A multichassis LAG (MCLAG) provides node-level redundancy by grouping two FortiSwitch models together so that they appear as a single switch on the network. If either switch fails, the MCLAG continues to function without any interruption, increasing network resiliency and eliminating the delays associated with the Spanning Tree Protocol (STP). For the network topology, see [Dual-homed servers connected to FortiLink tier-1 FortiSwitch units using an MCLAG on page 1938](#) and [Standalone FortiGate unit with dual-homed FortiSwitch access on page 1939](#).

Notes

- Both peer switches should be of the same hardware model and same software version. Mismatched configurations might work but are unsupported.
- There is a maximum of two FortiSwitch models per MCLAG.
- The routing feature is not available within an MCLAG.
- For static MAC addresses within an MCLAG, if one FortiSwitch learns the MAC address, the second FortiSwitch will automatically learn the MAC address.

To configure an MCLAG with managed FortiSwitch units:

1. For each MCLAG peer switch, log into the FortiSwitch to create a LAG:

```

config switch trunk
    edit "LAG-member"
        set mode lacp-active
        set mclag-icl enable
        set members "<port>" "<port>"
    next

```

2. Enable the MCLAG on each managed FortiSwitch:

```
config switch-controller managed-switch
  edit "<switch-id>"
    config ports
      edit "<trunk name>"
        set type trunk
        set mode {static | lacp-passive | lacp-active}
        set bundle {enable | disable}
        set members "<port>,<port>"
        set mclag {enable | disable}
      next
    end
  next
```

3. Log into each managed FortiSwitch to check the MCLAG configuration:

```
diagnose switch mclag
```

After the FortiSwitch units are configured as MCLAG peer switches, any port that supports advanced features on the FortiSwitch can become a LAG port. When `mclag` is enabled and the LAG port names match, an MCLAG peer set is automatically formed. The member ports for each FortiSwitch in the MCLAG do not need to be identical to the member ports on the peer FortiSwitch.

Configuring storm control

Storm control uses the data rate (packets/sec, default 500) of the link to measure traffic activity, preventing traffic on a LAN from being disrupted by a broadcast, multicast, or unicast storm on a port.

When the data rate exceeds the configured threshold, storm control drops excess traffic. You can configure the types of traffic to drop: broadcast, unknown unicast, or multicast.

The storm control settings are global to all of the non-FortiLink ports on the managed switches. Use the following CLI commands to configure storm control:

```
config switch-controller storm-control
  set rate <rate>
  set unknown-unicast {enable | disable}
  set unknown-multicast {enable | disable}
  set broadcast {enable | disable}
end
```

You can override the global storm control settings for a FortiSwitch using the following commands:

```
config switch-controller managed-switch
  edit <switch-id>
    config storm-control
      set local-override enable
```

At this point, you can configure the storm control settings that apply to this specific switch.

Displaying port statistics

Port statistics will be accessed using the following FortiSwitch CLI command:

```
FG100D3G15804763 # diagnose switch-controller dump port-stats
S124DP3X16000413 port8
```

```

S124DP3X16000413 0 :
{
  "port8":{
    "tx-bytes":823526672,
    "tx-packets":1402390,
    "tx-ucast":49047,
    "tx-mcast":804545,
    "tx-bcast":548798,
    "tx-errors":0,
    "tx-drops":3,
    "tx-oversize":0,
    "rx-bytes":13941793,
    "rx-packets":160303,
    "rx-ucast":148652,
    "rx-mcast":7509,
    "rx-bcast":4142,
    "rx-errors":0,
    "rx-drops":720,
    "rx-oversize":0,
    "undersize":0,
    "fragments":0,
    "jabbers":0,
    "collisions":0,
    "crc-alignments":0,
    "l3packets":0
  }
}

```

Configuring QoS with managed FortiSwitch units

Quality of Service (QoS) provides the ability to set particular priorities for different applications, users, or data flows.

NOTE: The FortiGate unit does not support QoS for hard or soft switch ports.

The FortiSwitch unit supports the following QoS configuration capabilities:

- Mapping the IEEE 802.1p and Layer 3 QoS values (Differentiated Services and IP Precedence) to an outbound QoS queue number.
- Providing eight egress queues on each port.
- Policing the maximum data rate of egress traffic on the interface.

To configure the QoS for managed FortiSwitch units:

1. Configure a Dot1p map.

A Dot1p map defines a mapping between IEEE 802.1p class of service (CoS) values (from incoming packets on a trusted interface) and the egress queue values. Values that are not explicitly included in the map will follow the default mapping, which maps each priority (0-7) to queue 0. If an incoming packet contains no CoS value, the switch assigns a CoS value of zero.

NOTE: Do not enable trust for both Dot1p and DSCP at the same time on the same interface. If you do want to trust both Dot1p and IP-DSCP, the FortiSwitch uses the latter value (DSCP) to determine the queue. The switch will use the Dot1p value and mapping only if the packet contains no DSCP value.

```
config switch-controller qos dot1p-map
```

```
edit <Dot1p map name>
  set description <text>
  set priority-0 <queue number>
  set priority-1 <queue number>
  set priority-2 <queue number>
  set priority-3 <queue number>
  set priority-4 <queue number>
  set priority-5 <queue number>
  set priority-6 <queue number>
  set priority-7 <queue number>
next
end
```

2. Configure a DSCP map.

A DSCP map defines a mapping between IP precedence or DSCP values and the egress queue values. For IP precedence, you have the following choices:

- network-control—Network control
- internetwork-control—Internetwork control
- critic-ecp—Critic and emergency call processing (ECP)
- flashoverride—Flash override
- flash—Flash
- immediate—Immediate
- priority—Priority
- routine—Routine

```
config switch-controller qos ip-dscp-map
edit <DSCP map name>
  set description <text>
  configure map <map_name>
  edit <entry name>
    set cos-queue <COS queue number>
    set diffserv {CS0 | CS1 | AF11 | AF12 | AF13 | CS2 | AF21 | AF22 | AF23
      | CS3 | AF31 | AF32 | AF33 | CS4 | AF41 | AF42 | AF43 | CS5 | EF |
      CS6 | CS7}
    set ip-precedence {network-control | internetwork-control | critic-ecp
      | flashoverride | flash | immediate | priority | routine}
    set value <DSCP raw value>
  next
end
end
```

3. Configure the egress QoS policy.

In a QoS policy, you set the scheduling mode for the policy and configure one or more CoS queues. Each egress port supports eight queues, and three scheduling modes are available:

- With strict scheduling, the queues are served in descending order (of queue number), so higher number queues receive higher priority.
- In simple round-robin mode, the scheduler visits each backlogged queue, servicing a single packet from each queue before moving on to the next one.
- In weighted round-robin mode, each of the eight egress queues is assigned a weight value ranging from 0 to 63.

```

config switch-controller qos queue-policy
  edit <QoS egress policy name>
    set schedule {strict | round-robin | weighted}
    config cos-queue
      edit [queue-<number>]
        set description <text>
        set min-rate <rate in kbps>
        set max-rate <rate in kbps>
        set drop-policy {taildrop | random-early-detection}
        set weight <weight value>
      next
    end
  next
end

```

4. Configure the overall policy that will be applied to the switch ports.

```

config switch-controller qos qos-policy
  edit <QoS egress policy name>
    set default-cos <default CoS value 0-7>
    set trust-dot1p-map <Dot1p map name>
    set trust-ip-dscp-map <DSCP map name>
    set queue-policy <queue policy name>
  next
end

```

5. Configure each switch port.

```

config switch-controller managed-switch
  edit <switch-id>
    config ports
      edit <port>
        set qos-policy <CoS policy>
      next
    end
  next
end

```

Synchronizing the FortiGate unit with the managed FortiSwitch units

You can synchronize the FortiGate unit with the managed FortiSwitch units to check for synchronization errors on each managed FortiSwitch unit.

Use the following command to synchronize the full configuration of a FortiGate unit with the managed FortiSwitch unit:

```
execute switch-controller trigger-config-sync <FortiSwitch_serial_number>
```

Use one of the following commands to display the synchronization state of a FortiGate unit with a specific managed FortiSwitch unit:

```

execute switch-controller get-sync-status switch-id <FortiSwitch_serial_number>
execute switch-controller get-sync-status name <FortiSwitch_name>

```

Use the following command to display the synchronization state of a FortiGate unit with a group of managed FortiSwitch units:

```
execute switch-controller get-sync-status group <FortiSwitch_group_name>
```

Use the following command to check the synchronization state of all managed FortiSwitch units in the current VDOM:

```
execute switch-controller get-sync-status all
```

For example:

```
FG100D3G14813513 (root) # execute switch-controller get-sync-status all
Managed-devices in current vdom root:
```

STACK-NAME: FortiSwitch-Stack-port5				
SWITCH (NAME)	STATUS	CONFIG	MAC-SYNC	UPGRADE
FS1D243Z14000173	Up	Idle	Idle	Idle
S124DP3X16006228 (Desktop-Switch)	Up	Idle	Idle	Idle

Replacing a managed FortiSwitch unit

If a managed FortiSwitch unit has a hardware issue, you can replace it with another FortiSwitch unit with the same model. The replacement FortiSwitch unit will inherit the configuration of the FortiSwitch unit that it replaces.

To replace a managed FortiSwitch unit:

1. Go to *WiFi & Switch Controller > Managed FortiSwitch*.
2. Select the faceplate of the FortiSwitch unit with the hardware issue.
3. Select *Deauthorize*.
4. In the CLI, enter the following command:

```
execute replace-device fortiswitch <existing_FortiSwitch_serial_number> <replacement_
FortiSwitch_serial_number>
```

For example:

```
execute replace-device fortiswitch S124DN3W16002025 S124DN3W16002026
```

NOTE: The two FortiSwitch serial numbers must belong to the same model.

Troubleshooting

Troubleshooting FortiLink issues

If the FortiGate does not establish the FortiLink connection with the FortiSwitch, perform the following troubleshooting checks.

Check the FortiGate configuration

To use the FortiGate GUI to check the FortiLink interface configuration:

1. In *Network > Interfaces*, double-click the interface used for FortiLink.
2. Ensure that *Dedicated to FortiSwitch* is set for this interface.

To use the FortiGate CLI to verify that you have configured the DHCP and NTP settings correctly:

1. Verify that the NTP server is enabled and that the FortiLink interface has been added to the list:

```
show system ntp
```

2. Ensure that the DHCP server on the Fortilink interface is configured correctly:

```
show system dhcp
```

Check the FortiSwitch configuration

To use FortiSwitch CLI commands to check the FortiSwitch configuration:

1. Verify that the switch system time matches the time on the FortiGate:

```
get system status
```

2. Verify that FortiGate has sent an IP address to the FortiSwitch (anticipate an IP address in the range 169.254.x.x):

```
get system interfaces
```

3. Verify that you can ping the FortiGate IP address:

```
exec ping x.x.x.x
```

To use FortiGate CLI commands to check the FortiSwitch configuration:

1. Verify that the connections from the FortiGate to the FortiSwitch units are up:

```
exec switch-controller get-conn-status
```

2. Verify that ports for a specific FortiSwitch stack are connected to the correct locations:

```
exec switch-controller get-physical-conn <FortiSwitch-Stack-ID>
```

3. Verify that all the ports for a specific FortiSwitch are up:

```
exec switch-controller get-conn-status <FortiSwitch-device-ID>
```

Check FortiSwitch connections

Use the following CLI command for detailed diagnostic information on the managed FortiSwitch connections:

```
execute switch-controller diagnose-connection <FortiSwitch_serial_number>
```

If the FortiSwitch serial number is omitted, only the FortiLink configuration is checked.

Chapter 17 - Networking

Introduction

This document explains how to configure your network. The following chapters are included in this document:

[Interfaces](#) explains the concepts of options for setting up interfaces and groupings of subnetworks that can scale to a company's growing requirements.

[DNS](#) explains how to set DNS requirements for your network and how to set FortiGate as a local DNS server.

[Advanced static routing](#) explains universal and static routing concepts, equal cost multipath (ECMP) and load balancing, policy routing, and routing in transparent mode.

[Dynamic routing](#) provides an overview of dynamic routing, compares static and dynamic routing, and describes dynamic routing protocols (RIP, OSPF, BGP, and IS-IS).

[Multicast forwarding](#) explains the concepts and use of multicasting with FortiGate.

[SD-WAN](#) describes FortiOS 6.0 features for SD-WAN.

[Troubleshooting](#) describes features, such as packet capture, that are useful for troubleshooting purposes.

What's new in FortiOS 6.0

The following list contains new Networking features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- ["Range for DHCPv6 prefix delegation" on page 2006](#)
- ["Configuring TFTP servers" on page 2008](#)
- TWAMP enhancements, see ["TWAMP" on page 2024](#)
- ["Link health monitor" on page 2025](#)
- ["VLANs over VXLANs" on page 2043](#)
- ["Enhanced MAC VLANs" on page 2049](#)
- ["VLAN filters for virtual wire pairs" on page 2053](#)
- Internet services enhancements, see ["Internet services" on page 2061](#)
- ["Static routes and VRFs" on page 2073](#)
- ["Source prefixes for static routes in transparent mode" on page 2084](#)
- IPv6 BFD support, see ["BFD" on page 2106](#)
- ["BFD and static routes" on page 2107](#)
- ["OSPF and VRFs" on page 2158](#)
- IS-IS support for IPv6, see ["IS-IS" on page 2224](#)
- Support for loopback interfaces with IS-IS, see ["Loopback interfaces" on page 2229](#)
- ["SD-WAN" on page 2273](#)

Interfaces

Interfaces, both physical and virtual, allow traffic to flow between internal networks and the Internet, and between internal networks. FortiGate has a number of options for setting up interfaces and groupings of subnetworks that can scale to your organization's growing requirements.

Administrative access

To help prevent FortiGate interfaces, especially the public-facing ports, from being accessed by users who you don't want accessing them, you can configure protocols that an administrator must use to access FortiGate, including:

- HTTPS
- PING
- FortiManager Access (FMG-Access)
- CAPWAP
- SSH
- SNMP
- FTM
- RADIUS Accounting
- FortiTelemetry

As a best practice, you should configure administrative access when you're setting the IP address for the port.

The following example adds the IPv4 address 172.20.120.100 to the WAN1 interface, and administrative access to HTTPS and SSH.

Add an IP address to the WAN1 interface - GUI

1. Go to **Network > Interfaces**.
2. Select the WAN1 interface row and select **Edit**.
3. Select the **Addressing Mode** of **Manual**.
4. Enter the IP address for the port of 172.20.120.100/24.
5. For **Administrative Access**, select **HTTPS** and **SSH**.
6. Select **OK**.

Add an IP address to the WAN1 interface - CLI

```
config system interface
  edit wan1
    set ip 172.20.120.100/24
    set allowaccess https ssh
  next
end
```

When you add or remove a protocol, you must type the entire list of protocols again. For example, if you have an access list of HTTPS and SSH and you want to add PING, you must use the following CLI command:

```
set allowaccess https ssh ping
```

If you use `set allowsaccess ping`, only ping is set and HTTPS and SSH are removed.

Aggregate interfaces

Link aggregation (IEEE 802.3ad) allows you to bind two or more physical interfaces together to form an aggregated link. This new link has the bandwidth of all the links combined. If a link in the group fails, traffic is automatically transferred to the remaining interfaces with the only noticeable effect being reduced bandwidth.

This is similar to redundant interfaces, with the major difference being that a redundant interface group uses only one link at a time, while an aggregate link group uses the total bandwidth of the functioning links in the group, up to eight (or more).

Some FortiGate models support the IEEE standard 802.3ad for link aggregation.

An interface can be an aggregate interface if it meets the following criteria:

- It's a physical interface, not a VLAN interface or subinterface.
- It's not already part of an aggregate or redundant interface.
- It's in the same VDOM as the aggregated interface. Aggregate ports can't span multiple VDOMs.
- It doesn't have an IP address and isn't configured for DHCP or PPPoE.
- It's not referenced in any security policy, VIP, IP pool, or multicast policy.
- It's not an HA heartbeat interface.
- It's not one of the backplane interfaces of the FortiGate 5000 series.

Some FortiGate models don't support aggregate interfaces. In this case, the aggregate option isn't available in the FortiGate GUI or CLI. Also, you can't create aggregate interfaces from interfaces in a switch port.

To see if a port is being used or has other dependencies - CLI:

```
diagnose sys checkused system.interface.name <interface_name>
```

When an interface is included in an aggregate interface, it's not listed in the **Network > Interfaces** page in the FortiGate GUI. Interfaces still appear in the CLI, but if you configure those interfaces, it won't take effect. You can't configure the interface individually and it's not available to include in security policies, VIPs, IP pools, or routing.

To avoid unintentional network issues when you configure Link Aggregation Control Protocol (LACP), disconnect the interfaces that you want to add to the aggregate interface. After you finish configuring LACP, reconnect the interfaces.

The following example creates an aggregate interface on a FortiGate, using ports 4 to 6, with an internal IP address of 10.13.101.100, and administrative access to HTTPS and SSH.

To create an aggregate interface - GUI:

1. Go to **Network > Interfaces** and select **Create New**, then **Interface**.
2. Enter the Name as `Aggregate`.
3. For the **Type**, select **802.3ad Aggregate**.
If this option doesn't appear, the FortiGate doesn't support aggregate interfaces.
4. In the **Physical Interface Members**, click to add interfaces. Select port 4, 5, and 6.
5. Select the **Addressing Mode** of **Manual**.
6. Enter the IP address for the port of 10.13.101.100/24.
7. For **Administrative Access**, select HTTPS and SSH.
8. Select **OK**.

To create aggregate interface - CLI:

```
config system interface
edit aggregate
set type aggregate
set member port4 port5 port6
set vdom root
set ip 172.20.120.100/24
set allowaccess https ssh
next
end
```

Sending GARP on aggregate MAC changes

A FortiGate sends out Gratuitous Address Resolution Protocol (GARP) announcements if the MAC address of a link aggregated interface changes to a new IP pool address due to a link failure or change in ports. This is needed when you use networking devices, such as some switches that don't perform this function when they receive LACP (Link Aggregation Control Protocol) information about changes in the MAC information.

DHCP addressing mode on an interface

If you configure an interface to use DHCP, FortiGate automatically broadcasts a DHCP request from the interface. The interface is configured with the IP address, any DNS server addresses, and the default gateway address that the DHCP server provides.

DHCP IPv6 is similar to DHCP IPv4, except:

- No default gateway option is defined because a host learns the gateway using router advertisement messages.
- There are no WINS servers because it is obsolete.

For more information about DHCP IPv6, see [RFC 3315](#).

You can configure DHCP for an interface in **Network > Interfaces** in the FortiGate GUI. Select the interface from the list, and select **DHCP** in the **Addressing mode**. The following table describes the DHCP status information when DHCP is configured for an interface.

Field	Description
Status	<p>Displays DHCP status messages as the interface connects to the DHCP server and gets addressing information. Select Status to refresh the addressing mode status message.</p> <p>Status can be one of the following values:</p> <ul style="list-style-type: none"> • initializing: no activity • connecting: interface attempts to connect to the DHCP server • connected: interface retrieves an IP address, netmask, and other settings from the DHCP server • failed: interface was unable to retrieve an IP address and other settings from the DHCP server
Obtained IP/Netmask	The IP address and netmask leased from the DHCP server. This is only displayed if the Status is connected .
Renew	Select this to renew the DHCP license for this interface. This is only displayed if the Status is connected .
Expiry Date	The time and date when the leased IP address and netmask is no longer valid for the interface. The IP address is returned to the pool to be allocated to the next user request for an IP address. This is only displayed if the Status is connected .
Default Gateway	The IP address of the gateway defined by the DHCP server. This is displayed only if the Status is connected , and if Receive default gateway from server is selected.
Distance	Enter the administrative distance for the default gateway retrieved from the DHCP server. The administrative distance is an integer from 1 to 255, and specifies the relative priority of a route when there are multiple routes to the same destination. A lower administrative distance indicates a more preferred route.
Retrieve default gateway from server	Enable this to retrieve a default gateway IP address from the DHCP server. The default gateway is added to the static routing table.
Override internal DNS	<p>Enable this to use the DNS addresses retrieved from the DHCP server instead of the DNS server IP addresses on the DNS page.</p> <p>When VDOMs are enabled, you can override the internal DNS only on the management VDOM.</p>

DHCP servers and relays

A DHCP server provides an address, from a defined address range, to a client on the network that requests it.

An interface can't provide both a server and a relay for connections of the same type (regular or IPsec). However, you can configure a regular DHCP server on an interface only if the interface is a physical interface with a static IP address. You can configure an IPsec DHCP server on an interface that has either a static or a dynamic IP address.

You can configure one or more DHCP servers on any FortiGate interface. A DHCP server dynamically assigns IP addresses to hosts on the network connected to the interface. The host computers must be configured to obtain their IP addresses using DHCP.

If an interface is connected to multiple networks through routers, you can add a DHCP server for each network. The IP range of each DHCP server must match the network address range. The routers must be configured for DHCP relay.

You can configure a FortiGate interface as a DHCP relay. The interface forwards DHCP requests from DHCP clients to an external DHCP server and returns the responses to the DHCP clients. The DHCP server must have appropriate routing so that its response packets to the DHCP clients arrive at the unit.

DHCP server options aren't available in transparent mode.

Configuring DHCP servers

To add a DHCP server, go to **Network > Interfaces**. Edit the interface, and select **DHCP** in the addressing mode.

Field	Description
Address Range	By default, the FortiGate unit assigns an address range based on the address of the interface for the complete scope of the address. For example, if the interface address is 172.20.120.230, the default range created is 172.20.120.231 to 172.20.120.254. Select the range and select Edit to adjust the range or select Create New to add a different range.
Netmask	Enter the netmask of the addresses that the DHCP server assigns.
Default Gateway	Select this to use either Same as Interface IP or select Specify and enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
DNS Server	Select this to use Same as system DNS , Same as Interface IP or select Specify and enter the IP address of the DNS server.
Mode	Select the type of DHCP server FortiGate will be. By default, it is a Server . Select Relay if needed. When Relay is selected, the above configuration is replaced by a field to enter the DHCP Server IP address.
DHCP Server IP	This appears only when Mode is Relay . Enter the IP address of the DHCP server where FortiGate obtains the requested IP address.

Field	Description
Type	Select this to use the DHCP in Regular or IPsec mode.
Additional DHCP Options	Use this to create new DHCP options.
MAC Address + Access Control	Select this to match an IP address from the DHCP server to a specific client or device using its MAC address. In a typical situation, an IP address is assigned ad hoc to a client, and that assignment times out after a specific time of inactivity from the client, known as the lease time. To ensure a client or device always has the same IP address (there is no lease time), use IP reservation.
Add from DHCP Client List	If the client is currently connected and using an IP address from the DHCP server, you can select this option to select the client from the list.

DHCP Server

 Advanced...

Mode

Server

Relay

DHCP Server IP

Type

Regular

IPsec

```
edit <name>
    set dhcp-relay-agent-option {enable | disable}
next
end
```

For more information about the DHCP relay option, see [RFC 3046](#) (DHCP Relay Agent Information Option).

Configuring DHCP with IPv6

You can use DHCP with IPv6, using the CLI. To configure DHCP, ensure IPv6 is enabled by going to **System > Feature Visibility** and enable **IPv6** under **Basic Features**. Use the following CLI command:

```
config system dhcp6 server
```

For more information about the configuration options, see the [FortiOS CLI Reference](#).

DHCPv6 prefix delegation

FortiGate supports prefix delegation for DHCP for IPv6 addressing. It's not practical to manually provision networks on a large scale in IPv6 networking. You can use DHCPv6 prefix delegation to assign a network address prefix, and automate the configuration and provisioning of the public routable addresses for the network.

To enable the prefix delegation - CLI:

```
config system interface
    edit "wan1"
        config ipv6
            set ip6-mode dhcp
            set ip6-allowaccess ping
            set dhcp6-prefix-delegation enable
        next
    next
end
```

Range for DHCPv6 prefix delegation

You can configure a range for DHCPv6 server prefix delegation. You can add a prefix range (starting and ending prefixes) and a prefix length. The prefix length determines the length of the prefix that the FortiGate sends downstream.

To configure a range for DHCPv6 prefix delegation – CLI:

```
config system dhcp6 server
    edit <id>
        config prefix-range
            edit <id>
                set start-prefix <prefix>
                set end-prefix <prefix>
                set prefix-length <length>
            next
        next
    next
end
```

DHCPv6 prefix hint

This feature is used to "hint" to upstream DHCPv6 servers a desired prefix length for their subnet to be assigned in response to its request.

There is a possibility of duplicate prefixes being sent by ISP when using a /64 bit subnet because the first 64 bits of the address are derived from the MAC address of the interface. This could cause an issue if the system administrator wishes to divide the host networks into 2 /64 bit subnets.

By receiving a /60 bit (for example) network address, the administrator can then divide the internal host works without the danger of creating duplicate subnets.

Also included in the new feature, are preferred times for the life and valid life of the DHCP lease.

DHCPv6 hint for the prefix length:

```
set dhcp6-prefix-hint <DHCPv6 prefix that will be used as a hint to the upstream DHCPv6 server>
```

DHCPv6 hint for the preferred life time:

```
set dhcp6-prefix-hint-plt <integer> 1 ~ 4294967295 seconds or "0" for unlimited lease time
```

DHCPv6 hint for the valid life time:

```
set dhcp6-prefix-hint-vlt <integer> 1 ~ 4294967295 seconds or "0" for unlimited lease time
```

Service

On low-end FortiGate units, a DHCP server is configured on the internal interface, by default, with the following values:

Field	Value
Address Range	192.168.1.110 to 192.168.1.210
Netmask	255.255.255.0
Default Gateway	192.168.1.99
Lease Time	7 days
DNS Server 1	192.168.1.99

These settings are appropriate for the default internal interface IP address of 192.168.1.99. If you change this address to a different network, you need to change the DHCP server settings to match.

Alternatively, after the FortiGate unit assigns an address, you can go to **Monitor > DHCP Monitor** and locate the specific user. Right-click and select **Create/Edit IP Reservation**.

Configuring the lease time

The lease time determines the length of time an IP address remains assigned to a client. Once the lease expires, the address is released for allocation to the next client that requests an IP address.

To configure the lease time, use the following CLI commands:

```
config system dhcp server
```

```
edit <server_entry_number>
    set lease-time <seconds>
next
end
```

The default lease time is seven days. To have an unlimited lease time, set the value to zero.

Configuring TFTP servers

You can configure multiple Trivial File Transfer Protocol (TFTP) servers for a Dynamic Host Configuration Protocol (DHCP) server. For example, you may want to configure a main TFTP server and a backup TFTP server.

The `tftp-server` command allows you to configure the TFTP servers, using either their hostnames or IP addresses. Separate multiple server entries with spaces.

To configure TFTP servers - CLI:

```
config system dhcp server
    edit <server ID>
        set tftp-server <hostname/IP address> <hostname/IP address>
    next
end
```

Configuring the DHCP renew time

You can set a minimum DHCP renew time. This option is available only when `mode` is set to `dhcp`.

To set the DHCP renew time - CLI:

```
config system interface
    edit <name>
        set mode dhcp
        set dhcp-renew-time <seconds>
    next
end
```

The possible values for `dhcp-renew-time` are 300 to 605800 seconds (five minutes to seven days). To use the renew time that the server provides, set this entry to 0.

DHCP options

When you add a DHCP server, you can include DHCP codes and options. The DHCP options are BOOTP vendor information fields that provide additional vendor-independent configuration parameters to manage the DHCP server. For example, you may need to configure a FortiGate DHCP server that gives out a separate option, as well as an IP address, such as an environment that needs to support PXE boot with Windows images.

The option numbers and codes are specific to a particular application. The documentation for the application should provide the values you should use. Option codes are represented in option value and HEX value pairs. The option is a value between 1 and 255.

You can add up to three DHCP code/option pairs per DHCP server.

To configure option 252 with value `http://192.168.1.1/wpad.dat` - CLI:

```
config system dhcp server
    edit <server_entry_number>
```

```

        set option1 252 687474703a2f2f3139322e3136382e312e312f777061642e646174
    next
end

```

For more information about DHCP options, see [RFC 2132](#) (DHCP Options and BOOTP Vendor Extensions).

FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses

As clients are assigned IP addresses, they send back information that would be found in an A record to the FortiGate DHCP server, which can take this information and pass it back to a corporate DNS server so that even devices using leased IP address can be reached using FQDNs. You can configure the settings for this feature using the `ddns-update` CLI command and some other `ddns` related options.

DHCP server option fields

In place of specific fields, the DHCP server maintains a table for the potential options. The FortiOS DHCP server supports up to a maximum of 30 custom options. These optional fields are set in the CLI.

To get to the DHCP server - CLI:

```

config system dhcp server
    edit <integer - ID of the specific DHCP server>

```

To configure the options, use the following CLI command:

```

config options

```

Once you are in the options context, create an ID for the table entry, using the following CLI commands:

```

edit <integer>
    set code <integer between 0 - 4294967295 to determine the DHCP option>
    set type [ hex | string | ip ]
    set value <option content for DHCP option types hex and string>
    set ip <option content for DHCP option type ip>
end

```

Excluding addresses in DHCP

If you have a large address range for the DHCP server, you can block a range of addresses that won't be included in the available addresses for the connecting users.

To exclude addresses in DHCP - CLI:

```

config system dhcp server
    edit <server_entry_number>
        config exclude-range
            edit <sequence_number>
                set start-ip <address>
                set end-ip <address>
            next
        next
    next
end

```

Viewing information about DHCP server connections

To view information about DHCP server connections, go to **Monitor > DHCP Monitor**. On this page, you can also add IP addresses to the reserved IP address list.

Breaking an address lease

If you need to end an IP address lease, you can break the lease. This is useful if you have limited addresses and longer lease times when some leases are no longer necessary, for example, with corporate visitors.

To break a lease - CLI:

```
execute dhcp lease-clear <ip_address>
```

Interface MTU packet size

You can change the maximum transmission unit (MTU) of the packets that FortiGate transmits to improve network performance. Ideally, the MTU should be the same as the smallest MTU of all the networks between FortiGate and the destination of the packets. If the packets that the FortiGate sends are larger than the smallest MTU, they're broken up or fragmented, which slows down transmission. You can easily experiment by lowering the MTU to find an MTU size for optimum network performance.

- 68 to 1500 bytes for static mode
- 576 to 1500 bytes for DHCP mode
- 576 to 1492 bytes for PPPoE mode
- Larger frame sizes (if supported by the FortiGate model), up to 9216 bytes for NP2, NP4, and NP6-accelerated interfaces

This option is available only for physical interfaces. Virtual interfaces associated with a physical interface inherit the physical interface MTU size.

Interfaces on some FortiGate models support frames larger than the traditional 1500 bytes. Jumbo frames are supported on FortiGate models that have either a SOC2 or NP4lite (except for the FortiGate 30D), and on FortiGate 100D series models. For information about your FortiGate model's hardware, see the [FortiOS Hardware Acceleration Handbook](#). To find out the maximum frame size that's supported for other models, visit the [Fortinet Support](#) website.

If you need to send larger frames over a route, all Ethernet devices on that route must support the larger frame size. Otherwise, the larger frames won't be recognized and will be dropped.

If you have standard size and larger size frame traffic on the same interface, routing alone can't route them to different routes based only on frame size. However, you can use VLANs to make sure the larger frame traffic is routed over network devices that support the larger size. VLANs inherit the MTU size from the parent interface. You must configure the VLAN to include both ends of the route, as well as all switches and routers along the route.

You can configure the MTU packet size. If you select an MTU size larger than your FortiGate model supports, an error message will indicate this. In this situation, try configuring a smaller MTU size until the value is supported.

In transparent mode, if you change the MTU of an interface, you must change the MTU of all interfaces on FortiGate to match the new MTU.

To change the MTU size - CLI:

```

config system interface
  edit <interface name>
    set mtu-override enable
    set mtu <byte size>
  next
end

```

Interface settings

You configure FortiGate interfaces, both physical and virtual, in **Network > Interfaces** in the FortiGate GUI. There are different options for configuring interfaces when FortiGate is in NAT mode or transparent mode.

On FortiOS Carrier, you can also enable the Gi gatekeeper on each interface for anti-overbilling.

Field	Description
Create New	<p>Select this to add a new interface, zone, or virtual wire pair.</p> <p>Depending on the FortiGate model, you can add a VLAN interface, a loopback interface, an IEEE 802.3ad aggregated interface, or a redundant interface.</p> <p>When VDOMs are enabled, you can also add Inter-VDOM links.</p>
Name	<p>The names of the physical interfaces on FortiGate. This includes any alias names that have been configured.</p> <p>When you combine several interfaces into an aggregate or redundant interface, only the aggregate or redundant interface is listed, and not the component interfaces.</p> <p>If you added VLAN interfaces, they appear in the name list below the physical or aggregated interface to which they have been added.</p> <p>If you added loopback interfaces, they appear in the interface list below the physical interface to which they have been added. If software switch interfaces are configured, you can view them.</p> <p>If your FortiGate model supports AMC modules, the interfaces are named amc-sw1/1, amc-dw1/2, and so on.</p>
Type	The configuration type for the interface.
IP/Netmask	<p>The current IP address and netmask of the interface.</p> <p>In VDOM, when VDOMs are not all in NAT or transparent mode, some values may not be available for display and are displayed as “-”.</p>
Access	The administrative access configuration for the interface.

Field	Description
Administrative Status	<p>Indicates if the interface can be accessed for administrative purposes. If the administrative status is a green arrow, an administrator can connect to the interface using the configured access.</p> <p>If the administrative status is a red arrow, the interface is administratively down and can't be accessed for administrative purposes.</p>
Link Status	<p>The status of the interface physical connection. The link status can be up (green arrow) or down (red arrow). If the link status is up, the interface is connected to the network and accepting traffic. If the link status is down, the interface is either not connected to the network or there is a problem with the connection.</p> <p>You can't change the link status from the FortiGate GUI, and it typically indicates that an Ethernet cable is plugged into the interface.</p> <p>The link status is only displayed for physical interfaces.</p>
MAC	The MAC address of the interface.
Mode	The addressing mode of the interface. This value can be manual, DHCP, or PPPoE.
Secondary IP	The secondary IP addresses added to the interface.
MTU	The maximum number of bytes per transmission unit for the interface.
Virtual Domain	The virtual domain to which the interface belongs. This column is visible when VDOM configuration is enabled.
VLAN ID	The configured VLAN ID for VLAN subinterfaces.

Interface configuration and settings

To configure an interface, go to **Network > Interfaces**, and select **Create New**.

Name	Enter the name of the interface. Physical interface names can't be changed.
Alias	<p>Enter an alternate name for a physical interface on the FortiGate unit. This field appears when you edit an existing physical interface.</p> <p>The alias is a maximum of 25 characters. The alias name doesn't appear in logs.</p>
Link Status	Indicates whether the interface is connected to a network (link status is Up) or not (link status is Down). This field appears when you edit an existing physical interface.

Type	<p>Select the type of interface you want to add.</p> <p>On some FortiGate models, you can set Type to 802.3ad Aggregate or Redundant Interface.</p>
Interface	<p>This is displayed when Type is set to VLAN.</p> <p>Select the name of the physical interface that you want to add a VLAN interface to. Once created, the VLAN interface is listed below its physical interface in the Interface list.</p> <p>You can't change the physical interface of a VLAN interface except when you add a new VLAN interface.</p>
VLAN ID	<p>This is displayed when Type is set to VLAN.</p> <p>Enter the VLAN ID. You can't change the VLAN ID except when you add a new VLAN interface.</p> <p>The VLAN ID must be a number between 1 and 4094. It must match the VLAN ID that the IEEE 802.1Q-compliant router or switch that is connected to the VLAN subinterface adds.</p>
Virtual Domain	<p>Select the virtual domain to add the interface to.</p> <p>Administrator accounts with the super_admin profile can change the Virtual Domain.</p>
Physical Interface Members	<p>This section can have two different formats depending on the interface type:</p> <ul style="list-style-type: none"> • Software switch interface: This section is a display-only field that shows the interfaces that belong to the virtual interface of the software switch. • 802.3ad aggregate or Redundant interface: This section includes the available interface list and the selected interface list. <p>Select interfaces from the Available Interfaces list and select the right arrow to add an interface to the Selected Interface list.</p>

Addressing mode	<p>Select the addressing mode for the interface:</p> <ul style="list-style-type: none"> • Select Manual and add an IP/Netmask for the interface. If IPv6 configuration is enabled, you can add both a IPv4 and an IPv6 IP address. • Select DHCP to get the interface IP address and other network settings from a DHCP server. • Select PPPoE to get the interface IP address and other network settings from a PPPoE server. • Select One-Arm Sniffer to enable the interface as a means to detect possible traffic threats. This option is available on physical ports that aren't configured for the primary Internet connection. • Select Dedicate to FortiAP/FortiSwitch to have a FortiAP or FortiSwitch device connect exclusively to the interface. This option is available only when you edit a physical interface and it has a static IP address. When you enter the IP address, FortiGate automatically creates a DHCP server using the subnet that you enter. This option is not available on the ADSL interface. <p>The FortiSwitch option is currently available only on the FortiGate 100D.</p>
IP/Netmask	If Addressing Mode is set to Manual , enter an IPv4 address and subnet mask for the interface. FortiGate interfaces can't have IP addresses on the same subnet.
IPv6 Address	If Addressing Mode is set to Manual and IPv6 support is enabled, enter an IPv6 address and subnet mask for the interface. A single interface can have an IPv4 address, IPv6 address, or both.
Administrative Access	Select the types of administrative access that you want to allow for IPv4 connections to this interface.
HTTPS	Allow secure HTTPS connections to the FortiGate GUI through this interface. If configured, this option will enable automatically when you select the HTTP option.
PING	The interface responds to pings. Use this setting to verify your installation and for testing.
HTTP	Allow HTTP connections to the FortiGate GUI through this interface. If configured, this option will also enable the HTTPS option.
SSH	Allow SSH connections to the CLI through this interface.
SNMP	Allow a remote SNMP manager to request SNMP information by connecting to this interface.
FMG-Access	Allow FortiManager authorization automatically during the communication exchanges between FortiManager and FortiGate devices.

CAPWAP	Allows the FortiGate wireless controller to manage a wireless access point, such as a FortiAP device.
IPv6 Administrative Access	Select the types of administrative access that you want to allow for IPv6 connections to this interface. The types are the same as for Administrative Access.
Security Mode	Select a captive portal for the interface. After you select this, you can define the portal message and the appearance of the GUI that users see when they log into the interface. You can also define one or more user groups that can access the interface.
DHCP Server	Select this to enable a DHCP server for the interface. For more information about configuring a DHCP server on the interface, see "DHCP servers and relays" on page 2002 .
Device Detection	Select this to allow the interface to be used with BYOD devices, such as iPhones. Define the device definitions by selecting User & Device > Device Inventory in the FortiGate GUI.
Enable Explicit Web Proxy	<p>Select this to enable explicit web proxying on this interface.</p> <p>This is available when you enable explicit proxy in the System Information Dashboard (System > Dashboard > Status).</p> <p>When you enable this, the interface will be displayed in System > Network > Explicit Proxy, under Listen on Interfaces, and web traffic on this interface will be proxied according to the Web Proxy settings.</p> <p>This option isn't available for a VLAN interface selection.</p>
Secondary IP Address	Add additional IPv4 addresses to this interface. Select the expand arrow to expand or hide the section.
Comments	Enter a description (up to 63 characters) to describe the interface.
Gi Gatekeeper (FortiOS Carrier only)	For FortiOS Carrier, enable this to enable the Gi firewall as part of the anti-overbilling configuration. You must also configure Gi Gatekeeper Settings by selecting System > Admin > Settings in the FortiGate GUI.

If you assign an interface to be part of a virtual wire pairing, the "role" value is removed from the interface.

Loopback interfaces

A loopback interface is a logical interface that's always up (no physical link dependency) and the attached subnet is always present in the routing table.

The IP address of the FortiGate loopback interface doesn't depend on one specific external port, and therefore you can access it through several physical or VLAN interfaces. You can configure multiple loopback interfaces in either non-VDOM mode or in each VDOM.

Loopback interfaces still require appropriate firewall policies to allow traffic to and from the interfaces.

A loopback interface can be used with:

- Management access
- BGP (TCP) peering
- PIM RP
- IS-IS

Loopback interfaces are a good practice for OSPF. To make troubleshooting OSPF easier, you should set the OSPF router ID to the same value as the loopback IP address, and remember the management IP addresses (ssh to “router ID”).

You can enable dynamic routing protocols on loopback interfaces.

For blackhole static routes, use the blackhole route type instead of the loopback interface.

VXLAN loopback binding

A Virtual Extensible LAN (VXLAN) unicast device can bind to a loopback interface as its underlying interface. The IP address of the loopback interface is taken as the source IP address for its outgoing VXLAN packets so the peer knows where to reply. Among the parameters that are passed to the kernel, the ifindex of the loopback interface isn't passed down to the kernel, so the kernel can choose the outgoing physical interface. This way, VXLAN traffic can be routed across multiple physical links and it provides resistance to a single point of failure.

To configure VXLAN loopback binding - CLI:

```
config system vxlan
  edit <name>
    set interface <interface>
    set vni <VXLAN network ID>
    set remote-ip <IP address>
  next
end
```

One-armed sniffer

You can use a one-armed sniffer to configure a FortiGate physical interface as a one-arm intrusion detection system (IDS). Traffic sent to the interface is examined for matches to the configured IPS sensor and application control list. Matches are logged and then all received traffic is dropped. Sniffing reports only on attacks. It does not deny or otherwise influence traffic.

You can use the one-arm sniffer to configure FortiGate to operate as an IDS appliance by sniffing network traffic for attacks without actually processing the packets. To configure one-arm IDS, you enable sniffer mode on a FortiGate interface and connect the interface to a hub, or to the SPAN port of a switch that is processing network traffic.

To assign an interface as a sniffer interface, select **Network > Interfaces**, edit the interface and select **One-Arm Sniffer**.

If the check box is not available, it means the interface is in use. Ensure that the interface isn't selected in any firewall policies, routes, virtual IPs, or other features in which a physical interface is specified.

Field	Description
Enable Filters	<p>Select this to include filters that define a more granular sniff of network traffic. Select specific hosts, ports, VLANs, and protocols.</p> <p>In all cases, enter a number or number range for the filtering type. For protocol values, the standard protocols are:</p> <ul style="list-style-type: none">• UDP - 17• TCP - 6• ICMP - 1
Include IPv6 Packets	If your network is running both IPv4 and IPv6 addressing, select this to sniff both addressing types. Otherwise, FortiGate will sniff only IPv4 traffic.
Include Non-IP Packets	Select this for a more intense scan of content in the traffic.
Security Profiles	IPS sensors and application control lists allow you to select specific sensors and applications that you want to identify within the traffic.

Ports preassigned as sniffer ports

Some FortiGate models have ports preconfigured as sniffer ports, by default. The models and ports preconfigured in sniffer mode are as follows:

- FortiGate 300D
 - Port4
 - Port8
- FortiGate 500D
 - Port5
 - Port6
 - Port13
 - Port14

Physical ports

FortiGate has several physical ports that you can connect Ethernet or optical cables to. Depending on the FortiGate model, it can have between 4 and 40 physical ports. Some units have a grouping of ports labeled as **lan**, that provide built-in switch functionality.

The port names, as labeled on the FortiGate, appear in the FortiGate GUI in the **Unit Operation** widget on the dashboard. They also appear when you configure the interfaces, in **Network > Interfaces**.

You can hover over the ports to see information about each port, such as the name of the port and the IP address.

For example, the following diagram shows the 22 interfaces of the FortiGate 100 D (Generation 2) as they appear in the dashboard in the FortiGate GUI.

Two of the physical ports on the FortiGate 100D (Generation 2) are SFP ports. These ports share the numbers 15 and 16 with RJ-45 ports. Because of this, when SFP port 15 is used, RJ-45 port 15 can't be used, and vice versa. These ports also share the same MAC address.

Configuring the FortiGate 100D ports

Normally, you can configure the internal interface as a single interface that's shared by all physical interface connections (a switch). The switch mode feature has two states: switch mode and interface mode. Switch mode is the default mode, with only one interface and one address for the entire internal switch. Interface mode allows you to configure each of the physical interface connections of the internal switch separately. This allows you to assign different subnets and netmasks to each of the internal physical interface connections.

The larger FortiGate models may also include Advanced Mezzanine Cards (AMC), which can provide additional interfaces (Ethernet or optical), with throughput enhancements for more efficient handling of specialized traffic. These interfaces appear in FortiOS as port `amc/sw1`, `amc/sw2`, and so on.

Displaying information about the status of transceivers

You can display information about the status of transceivers installed in FortiGate SFP/SFP+ interfaces, in the FortiGate CLI.

The `get system interface transceiver` command lists all of the SFP/SFP+ interfaces on FortiGate. If the interfaces include transceivers, the command output displays information about them, such as the vendor name, part number, and serial number. It also includes details about transceiver operation, such as temperature, voltage, and optical transmission power, which you can use to diagnose transmission problems.

The following example shows an output from using this command:

```
get system interface transceiver
...
Interface port14 - Transceiver is not detected.
Interface port15 - SFP/SFP+
```

```

Vendor Name   : FIBERXON INC.
Part No.      : FTM-8012C-SLG
Serial No.    : 101680071708917
Interface port16 - SFP/SFP+
Vendor Name   : FINISAR CORP.
Part No.      : FCLF-8521-3
Serial No.    : PS62ENQ

```

SFP/SFP+ Interface	Temperature (Celsius)	Voltage (Volts)	Optical Tx Bias (mA)	Optical Tx Power (dBm)	Optical Rx Power (dBm)
port15	N/A	N/A	N/A	N/A	N/A
port16	N/A	N/A	N/A	N/A	N/A

++ : high alarm, + : high warning, - : low warning, -- : low alarm, ? : suspect.

You can use this command on most FortiGate models that have SFP/SFP+ interfaces.

Split port support

The 5001D 40 GB can be split into 4 10 GB ports. You can do this through a combination of hardware and software configuration. You use a specific 40 GB connector to connect to the 40 GB port and typically, the other end of the fibre optic cable connects to another 40 GB port. However, you can use a special cable that is a single 40 GB connector at one end and 4 10 GB connections at the other end. To use this setup, you also have to configure the port to be a split port.

To configure split port support - CLI:

```

config system global
    set port-split port1 port2
end

```

The ports will be checked to make sure that they aren't in use or referenced by other policy configurations. If they are in use, the command is aborted. Changing the port to be a split port requires a system reboot.

PPPoE addressing mode on an interface

If you configure the interface to use PPPoE, the FortiGate automatically broadcasts a PPPoE request from the interface.

FortiGate devices support many PPPoE RFC features (RFC 2516) including unnumbered IPs, initial discovery timeout and PPPoE Active Discovery Terminate (PADT).

PPPoE is only configurable in the GUI on desktop FortiGate devices. 1U FortiGate devices and up must be configured in the CLI.

To configure PPPoE - CLI:

```

config system interface
    edit <port name>
        set mode pppoe
        set username <ISP username>
        set password <ISP password>
        set idle-timeout <seconds>
        set distance <integer>
    end
end

```

```

    set ipunnumbered <unnumbered IP>
    set disc-retry-timeout <seconds>
    set padt-retry-timeout <seconds>
    set lcp-echo-interval <seconds>
    set dns-server-override {enable | disable}
  next
end

```

To configure PPPoE - GUI:

Configure PPPoE on an interface in **Network > Interfaces**. The following table describes the PPPoE status information when PPPoE is configured for an interface.

Field	Description
Status	<p>Displays PPPoE status messages as the FortiGate connects to the PPPoE server and gets addressing information. Select Status to refresh the addressing mode status message.</p> <p>The status is only displayed if you selected Edit.</p> <p>Status can be any one of the following 4 messages.</p>
Initializing	No activity.
Connecting	The interface is attempting to connect to the PPPoE server.
Connected	<p>The interface retrieves an IP address, netmask, and other settings from the PPPoE server.</p> <p>When the status is connected, PPPoE connection information is displayed.</p>
Failed	The interface was unable to retrieve an IP address and other information from the PPPoE server.
Reconnect	<p>Select to reconnect to the PPPoE server.</p> <p>Only displayed if Status is connected.</p>
User Name	The username for the PPPoE account.
Password	The password for the PPPoE account.
Unnumbered IP	Specify the IP address for the interface. If your ISP has assigned you a block of IP addresses, use one of them. Otherwise, this IP address can be the same as the IP address of another interface or can be any IP address.
Initial Disc Timeout	Enter Initial discovery timeout. Enter the time to wait before starting to retry a PPPoE discovery.

Field	Description
Initial PADT timeout	Enter Initial PPPoE Active Discovery Terminate (PADT) timeout, in seconds. Use this timeout to shut down the PPPoE session if it's idle for the specified number of seconds. PADT must be supported by your ISP. Set the Initial PADT timeout to 0 to disable.
Distance	Enter the administrative distance for the default gateway retrieved from the PPPoE server. The administrative distance, an integer from 1-255, specifies the relative priority of a route when there are multiple routes to the same destination. A lower administrative distance indicates a more preferred route. The default distance for the default gateway is 1.
Retrieve default gateway from server	Enable to retrieve a default gateway IP address from a PPPoE server. The default gateway is added to the static routing table.
Override internal DNS	<p>Enable to replace the DNS server IP addresses on the System DNS page with the DNS addresses retrieved from the PPPoE server.</p> <p>When VDOMs are enabled, you can override the internal DNS only on the management VDOM.</p>

Probing interfaces

You can use server probes on FortiGate interfaces. First, you configure the probe response mode and then you give the probe response administrative access on the interface. You can configure one of the following probe response modes:

Mode	Description
none	Disable probe
http-probe	HTTP probe
twamp	Two-Way Active Measurement Protocol

To configure the probe - CLI:

```
config system probe-response
    set mode {none|http-probe|twamp}
end
```

To give the probe response administrative access to the interface - CLI:

```
config system interface
    edit <port>
        set allowaccess probe-response
    next
end
```

TWAMP

FortiOS supports Two-Way Active Measurement Protocol (TWAMP) Light, which is a simplified architecture within the TWAMP standard. Its purpose is to measure the round trip IP performance between any two devices within a network that supports the protocol. FortiOS supports both responder/reflector and server/controller roles.

FortiOS extends TWAMP to also support unidirectional network quality monitoring. You can monitor network quality for each direction of a traffic path separately. You can also use SNMP to monitor the network quality status from both the controller and responder sides.

You can use a link health monitor to see the following information:

- Directional latency (Minimum, Maximum, Average)
- Directional packet loss
- Directional out of sequence packets
- Directional jitter (Minimum, Maximum, Average)

To use TWAMP to monitor network quality - CLI:

```
config system link-monitor
  edit <name>
    set srcintf <interface name>
    set server <IP address>
    set protocol twamp
    set port <port number>
    set gateway-ip <IP address>
  next
end
```

To configure the probe to use TWAMP – CLI:

```
config system probe-response
  set mode twamp
  set timeout <time>
end
```

Redundant interfaces

On some models, you can combine two or more physical interfaces to provide link redundancy. This feature allows you to connect to two or more switches to ensure connectivity if one physical interface, or the equipment on that interface, fails.

In a redundant interface, traffic travels only over one interface at a time. This differs from an aggregated interface where traffic travels over all interfaces for distribution of increased bandwidth. This difference means that redundant interfaces can have more robust configurations with fewer possible points of failure. This is important in a fully-meshed HA configuration.

An interface can be in a redundant interface if:

- It's a physical interface, not a VLAN interface
- It's not already part of an aggregated or redundant interface
- It's in the same VDOM as the redundant interface
- It has no defined IP address
- It's not configured for DHCP or PPPoE

- It has no DHCP server or relay configured on it
- It doesn't have any VLAN subinterfaces
- It isn't referenced in any security policy, VIP, or multicast policy
- It isn't monitored by HA
- It isn't one of the FortiGate-5000 series backplane interfaces

When an interface is included in a redundant interface, it isn't listed on the **Network > Interfaces** page. You can't configure the interface individually and it isn't available for inclusion in security policies, VIPs, or routing.

Dual Internet connections

Dual internet connections, also referred to as dual WAN or redundant Internet connections, refers to using two FortiGate interfaces to connect to the Internet. You can use dual Internet connections in several ways:

- Redundant interfaces: If one interface goes down, the second interface automatically becomes the main Internet connection.
- Load sharing: This ensures better throughput.
- Use a combination of redundancy and load sharing.

Redundant interfaces

Redundant interfaces ensure that if your Internet access is no longer available through a certain port, the FortiGate uses an alternate port to connect to the Internet.

In this scenario, two interfaces, WAN1 and WAN2, are connected to the Internet using two different ISPs. WAN1 is the primary connection. In the event of a failure of WAN1, WAN2 automatically becomes the connection to the Internet. For this configuration to function correctly, you must configure the following settings:

- Configure a link health monitor to determine when the primary interface (WAN1) is down and when the connection returns.
- Configure a default route for each interface.
- Configure security policies to allow traffic through each interface to the internal network.

Link health monitor

Adding a link health monitor is required for routing failover traffic. A link health monitor confirms the connectivity of the device's interface. You can detect possible routing loops with link health monitors. You can configure the FortiGate to ping a gateway at regular intervals to ensure it's online and working. When the gateway isn't accessible, that interface is marked as down. After this configuration, when this interface on the FortiGate can't connect to the next router, the FortiGate brings down the interface.

Set the `Interval` (how often to send a ping) and `failtime` (how many lost pings are considered a failure). A smaller interval and smaller number of lost pings results in faster detection, but creates more traffic on your network. You may also want to log CPU and memory usage, as a network outage will cause your CPU activity to spike.

The link health monitor supports both IPv4 and IPv6. For IPv6, it supports the ping6 protocol only.

To add a link health monitor (IPv4) - CLI:

```
config system link-monitor
  edit <link-monitor-name>
    set addr-mode ipv4
```

```
set srcint <interface-name>
set server <server-IP-address>
set protocol {ping tcp-echo udp-echo http twamp}
set gateway-ip <gateway-IP-address>
set source-ip <IP-address>
set interval <seconds>
set failtime <retry-attempts>
set recoverytime <number-of-successful-responses>
set ha-priority <priority>
set update-cascade-interface {enable | disable}
set update-static-route {enable | disable}
set status enable
next
end
```

To add a link health monitor (IPv6) - CLI:

```
config system link-monitor
edit <link-monitor-name>
set addr-mode ipv6
set srcint <interface-name>
set server <server-IP-address>
set protocol ping6
set gateway-ip6 <gateway-IP-address>
set source-ip6 <IP-address>
set interval <seconds>
set failtime <retry-attempts>
set recoverytime <number-of-successful-responses>
set ha-priority <priority>
set update-cascade-interface {enable | disable}
set update-static-route {enable | disable}
set status enable
next
end
```

Routing

You must configure a default route for each interface and indicate which route is preferred by specifying the distance. The lower distance is declared active and placed higher in the routing table.

When you have dual WAN interfaces that are configured to provide failover, you might not be able to connect to the backup WAN interface because the FortiGate may not route traffic (even responses) out of the backup interface. The FortiGate performs a reverse path lookup to prevent spoofed traffic. If an entry can't be found in the routing table that sends the return traffic out the same interface, the incoming traffic is dropped.

To configure the routing of the two interfaces - GUI:

1. Go to **Network > Static Routes** and select **Create New**.
2. Enter the following information and select **OK**.

Destination IP/Mask	For an IPv4 route, enter a subnet of 0.0.0.0/0.0.0.0. For an IPv6 route, enter a subnet of ::/0.
Gateway	Enter the gateway address.
Interface	Select the primary connection. For example, WAN1 .
Administrative Distance	Leave as the default of 10.

- Repeat these steps to set **Interface** to **WAN2** and **Administrative Distance** to 20.

To configure the routing of the two interfaces - CLI:

```
config router {static | static6}
  edit 0
    set dst 0.0.0.0 0.0.0.0
    set device WAN1
    set gateway <gateway_address>
    set distance 10
  next
  edit 0
    set dst 0.0.0.0 0.0.0.0
    set device WAN2
    set gateway <gateway_address>
    set distance 20
  next
end
```

Security policies

When you create security policies, you need to configure duplicate policies to ensure that after traffic fails over WAN1, regular traffic is allowed to pass through WAN2, as it did with WAN1. This ensures that failover occurs with minimal effect to users. For more information about creating security policies, see the [FortiOS Firewall Handbook](#).

Load sharing

Load sharing allows you to use both connections to the Internet at the same time, but doesn't provide failover support. When configuring load sharing, you need to make sure that routing is configured for both external ports (for example, WAN1 and WAN2) have static routes with the same distance and priority.

Link redundancy and load sharing

In this scenario, both links are available to distribute Internet traffic over both links. Should one of the interfaces fail, the FortiGate will continue to send traffic over the other active interface. Configuration is similar to the Redundant interfaces configuration, with the main difference being that the configured routes should have equal distance settings.

This means both routes will remain active in the routing table. To make one interface the preferred interface, use a default policy route to indicate the interface that is preferred for accessing the Internet. If traffic matches the security policy, the policy overrides all entries in the routing table, including connected routes. You may need to add specific policy routes that override these default policy routes.

To redirect traffic over the secondary interface, create policy routes to direct some traffic onto it rather than the primary interface. When adding the policy route, only define the outgoing interface and leave the gateway blank. This ensures that the policy route won't be active when the link is down.

SSL VPN and WAN link load balancing

You can set virtual WAN link interfaces as destination interfaces in firewall policies for WAN link load balancing, when SSL VPN is the source interface. For example, you can log in to a FortiGate using an SSL VPN for traffic inspection and then have outbound traffic load balanced by WAN link load balancing.

You can set a virtual WAN link interface as a destination interface in a firewall policy where SSL VPN is the source interface, using either the FortiGate GUI (FortiOS 5.6.1 and later) or CLI.

To configure a virtual WAN link interface - CLI:

```
config firewall policy
  edit <policy ID>
    set dstintf virtual-wan-link
  next
end
```

Secondary IP addresses to an interface

If an interface is configured with a manual or static IP address, you can also add secondary static IP addresses to the interface. Adding secondary IP addresses effectively adds multiple IP addresses to the interface. Secondary IP addresses can't be assigned using DHCP or PPPoE.

All of the IP addresses added to an interface are associated with the single MAC address of the physical interface, and all secondary IP addresses are in the same VDOM as the interface that they're added to. You configure interface status detection for gateway load balancing separately for each secondary IP addresses. As with all other interface IP addresses, secondary IP addresses can't be on the same subnet as any other primary or secondary IP address assigned to a FortiGate interface unless they are in separate VDOMs.

To configure a secondary IP address, go to **Network > Interfaces**, select **Edit** or **Create New** and select the **Secondary IP Address** check box.

Software switch

A software switch, or soft switch, is a virtual switch that's implemented at the software, or firmware level, rather than the hardware level. A software switch can be used to simplify communication between devices connected to different FortiGate interfaces. For example, using a software switch, you can place the FortiGate interface connected to an internal network on the same subnet as your wireless interfaces. Then, devices on the internal network can communicate with devices on the wireless network without any additional configuration such as additional security policies, on the FortiGate.

It can also be useful if you require more hardware ports for the switch on a FortiGate. For example, if your FortiGate device has a 4-port switch, WAN1, WAN2 and DMZ interfaces, and you need one more port, you can create a soft switch that can include the 4-port switch and the DMZ interface all on the same subnet. These types of applications also apply to wireless interfaces and virtual wireless interfaces and physical interfaces, such as those with FortiWiFi and FortiAP devices.

Similar to a hardware switch, a software switch functions like a single interface. A software switch has one IP address; all of the interfaces in the software switch are on the same subnet. Traffic between devices connected to

each interface aren't regulated by security policies, and traffic passing in and out of the switch are affected by the same policy.

There are a few things to consider when setting up a software switch:

- Ensure you create a backup of the configuration.
- Ensure you have at least one port or connection such as the console port to connect to the FortiGate. If you accidentally combine too many ports, you will need a way to undo any errors.
- The ports that you include must not have any link or relation to any other aspect of the FortiGate. For example, DHCP servers, security policies, and so on.
- For increased security, you can create a captive portal for the switch, allowing only specific user groups access to the resources connected to the switch.
- To add an interface to a software switch, the interface can't be referenced by the existing configuration. It must also have its IP address set to 0.0.0.0/0.0.0.0.

To create a software switch - CLI:

```
config system switch-interface
    edit <switch-name>
        set type switch
        set member <interface_list>
    next
end
config system interface
    edit <switch_name>
        set ip <ip_address>
        set allowaccess https ssh ping
    next
end
```

Soft switch example

For this example, the wireless interface (Wi-Fi) needs to be on the same subnet as the DMZ1 interface to facilitate wireless syncing from an iPhone and a local computer. The syncing between two subnets is problematic. By putting both interfaces on the same subnet, the syncing will work. The software switch will accomplish this.

In this example, the soft switch includes a wireless interface. Remember to configure any wireless security before proceeding. If you leave this interface open without any password or other security, it leaves open access to not only the wireless interface but to any other interfaces and devices connected within the software switch.

Clear the interfaces and back up the configuration

First, ensure that the interfaces aren't being used with any other security policy or other use on the FortiGate. Check the Wi-Fi and DMZ1 ports to ensure that DHCP isn't enabled on the interface and there are no other dependencies with these interfaces.

Next, save the current configuration. In the event that something doesn't work, recovery can be quick.

Merge the interfaces

The plan is to merge the Wi-Fi port and DMZ1 port. This will create a software switch with a name of “synchro” with an IP address of 10.10.21.12. The following steps will create the switch, add the IP address and set administrative access for HTTPS, SSH, and Ping.

To merge the interfaces - CLI:

```
config system switch-interface
  edit synchro
    set type switch
    set member dmz1 wifi
  next
end
config system interface
  edit synchro
    set ip 10.10.21.12
    set allowaccess https ssh ping
  next
end
```

Final steps

With the switch set up, you can add security policies, DHCP servers, and any other configuration that you would normally do to configure interfaces on the FortiGate.

Virtual switch

The virtual switch feature allows you create virtual switches on top of physical switches with designated interfaces/ports so that a virtual switch can build up its forwarding table through learning and forward traffic accordingly. When traffic is forwarded among interfaces belonging to the same virtual switch, the traffic doesn't need to go up to the software stack, but is forwarded directly by the switch. When traffic has to be relayed to interfaces not on the virtual switch, the traffic will go through the normal data path and be offloaded to NP4, when possible.

This feature is only available on mid- to high-end FortiGate devices, including the 100D, 600C, 1000C, and 1240B.

To enable and configure the virtual switch - CLI:

```
config system virtual-switch
  edit vs1
    set physical-switch sw0
  config port
    edit 1
      set port port1
      set speed xx
      set duplex xx
      set status [up|down]
    edit 2
      set port port2
      set ...
    next
  next
end
```

Support for 802.1x fallback and 802.1x dynamic VLANs

There are four modes when enabling 802.1x on a virtual switch interface:

Mode	Description
Default	In this mode, it works as it did previously.
Fallback	In fallback mode, the virtual switch is treated as a master. Only one slave can refer to a fallback master. The ports in the master virtual switch are always authorized. After passing 802.1x authentication, the ports will stay authorized and move to its slave virtual switch.
Dynamic-vlan	In dynamic-vlan mode, the virtual switch is also treated as a master. However, many slaves can refer to a dynamic-vlan master. Those ports in the master virtual switch are always unauthorized. After passing 802.1x/MAB authentication, the ports are set to authorized and moved to one of its slave virtual switches.
Slave	In slave mode, a master must be set through security-8021x-master attribute. A slave virtual switch will use its master virtual switch's security-groups settings for authentication.

CLI example for fallback mode:

```

config system virtual-switch
  edit "fallsw"
    set physical-switch "sw0"
    config port
  next
  edit "trust"
    set physical-switch "sw0"
  next
config system interface
  edit "fallsw"
    set vdom "root"
    set ip 192.168.20.1 255.255.255.0
    set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct
    probereponse capwap
    set type hard-switch
    set security-mode 802.1X
    set security-8021x-mode fallback(fallback mode master switch)
    set security-groups "rds-grp" (the usergroup for 802.1x)
    set snmp-index 10
  next
  edit "trust"
    set vdom "root"
    set ip 192.168.22.1 255.255.255.0
    set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct
    probereponse
    set type hard-switch
    set security-mode 802.1X
    set security-8021x-mode slave(slave mode switch)
    set security-8021x-master "fallsw" (its master switch)
    set snmp-index 6
  next
end

```

CLI example for dynamic-vlan mode:

```
config system virtual-switch
edit "internal"
    set physical-switch "sw0"
edit "lan-trust"
    set physical-switch "sw0"
next
edit "lan-vlan1000"
    set physical-switch "sw0"
next
edit "lan-vlan2000"
    set physical-switch "sw0"
    config port
    edit "internal1" (normally we should not add port in slave switch. This is used if
        user wants to manually add one port in slave)
    next
end
config system interface
edit "internal"
    set vdom "root"
    set ip 192.168.11.99 255.255.255.0
    set allowaccess ping https ssh http fgfm capwap
    set type hard-switch
    set security-mode 802.1X
    set security-8021x-mode dynamic-vlan<-----dynamic-vlan mode master switch
    set security-groups "rds-grp"<-----the usergroup for 802.1x
    set snmp-index 15
next
edit "lan-trust"
    set vdom "root"
    set ip 192.168.111.99 255.255.255.0
    set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct
        proberesponse capwap
    set type hard-switch
    set security-mode 802.1X
    set security-8021x-mode slave<-----slave mode switch
    set security-8021x-master "internal"<-----its master switch
    set snmp-index 7
next
edit "lan-vlan1000"
    set vdom "root"
    set ip 192.168.110.1 255.255.255.0
    set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct
        proberesponse capwap
    set type hard-switch
    set security-mode 802.1X
    set security-8021x-mode slave<-----slave mode switch
    set security-8021x-master "internal"<-----its master switch
    set security-8021x-dynamic-vlan-id 1000 <-----the matching vlan id for this virtual
        switch
    set snmp-index 16
next
edit "lan-vlan2000"
    set vdom "root"
    set ip 192.168.220.1 255.255.255.0
```

```

        set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct
        proberesponse
    capwap
    set type hard-switch
    set security-mode 802.1X
    set security-8021x-mode slave
    set security-8021x-master "internal"
    set security-8021x-dynamic-vlan-id 2000
    set snmp-index 17
end
config user group
    edit "rds-grp"
        set dynamic-vlan-id 4000 (default vlan id if there is no vlan attribute return
        from server)
        set member "190"
    end
end

```

Zones

Zones are a group of one or more FortiGate interfaces, both physical and virtual, that you can apply security policies to to control inbound and outbound traffic. Grouping interfaces and VLAN subinterfaces into zones simplifies the creation of security policies where a number of network segments can use the same policy settings and protection profiles. When you add a zone, you select the names of the interfaces and VLAN subinterfaces to add to the zone. Each interface still has its own address and routing is still done between interfaces, that is, routing isn't affected by zones. You can create security policies to control the flow of intra-zone traffic.

For example, the network includes three separate groups of users representing different entities on the company network. While each group has its own set of port and VLANs, in each area, they can all use the same security policy and protection profiles to access the Internet. Rather than an administrator making nine separate security policies, an administrator can add the required interfaces to a zone and create three policies, making administration simpler.

You can configure policies for connections to and from a zone, but not between interfaces in a zone.

The following example shows how to set up a zone to include the internal interface and a VLAN.

To create a zone - GUI:

1. Go to **Network > Interfaces**.
2. Select the arrow on the **Create New** button and select **Zone**.
3. Enter a zone name of `Zone_1`.
4. Select the required **Interface Members**.
5. Select **OK**.

To create a zone - CLI:

```

config system zone
    edit Zone_1
        set interface internal VLAN_1
    next
end

```

Virtual domains

Virtual domains (VDMs) are a method of dividing a FortiGate into two or more virtual units that function as multiple independent units. A single FortiGate is then flexible enough to serve multiple departments of an organization, separate organizations, or to act as the basis for a service provider's managed security service.

VDMs provide separate security domains that allow separate zones, user authentication, security policies, routing, and VPN configurations. By default, each FortiGate has a VDM named root. This VDM includes all of the FortiGate physical interfaces, modem, virtual LAN (VLAN) subinterfaces, zones, security policies, routing settings, and VPN settings.

When a packet enters a VDM, it's confined to that VDM. In a VDM, you can create security policies for connections between VLAN subinterfaces or zones in the VDM. Packets don't cross the virtual domain border internally. To travel between VDMs, a packet must pass through a firewall on a physical interface. The packet then arrives at another VDM on a different interface, but it must pass through another firewall before entering the VDM. Both VDMs are on the same FortiGate. Inter-VDMs change this behavior because they are internal interfaces. However, their packets go through all the same security measures as on physical interfaces.

The following example shows how to enable VDMs on a FortiGate and the basic and create a VDM accounting on the DMZ2 port and assign an administrator to maintain the VDM. First, enable VDMs on the FortiGate. When you enable VDMs, the FortiGate will log you out.

For desktop and low-end FortiGate devices, you use the CLI to enable VDMs. Once you enable VDMs, all further configuration can be done using the GUI or the CLI. On larger FortiGate units, you can use the GUI or the CLI to enable VDMs.

To enable VDMs - GUI:

1. Go to **Dashboard**.
2. In the **System Information** widget, select **Enable** for **Virtual Domain**.

The FortiGate logs you out. Once you log back in, you'll notice that the menu structure has changed. This reflects the global settings for all VDMs:

To enable VDMs - CLI:

```
config system global
    set vdom-admin enable
end
```

Next, add the VDM called accounting.

To add a VDM - GUI:

1. Go to **System > VDM**, and select **Create New**.
2. Enter the VDM name `accounting`.
3. Select **OK**.

To add a VDM - CLI:

```
config vdom
    edit <new_vdom_name>
end
```

With the VDOM created, you can assign a physical interface to it and assign it an IP address.

To assign physical interface to the accounting VDOM - GUI:

1. Go to **Network > Interfaces**.
2. Select the DMZ2 port row and select **Edit**.
3. For the **Virtual Domain** drop-down list, select **accounting**.
4. Select the **Addressing Mode** of **Manual**.
5. Enter the IP address for the port of 10.13.101.100/24.
6. Set the **Administrative Access** to **HTTPS** and **SSH**.
7. Select **OK**.

To assign physical interface to the accounting VDOM - CLI:

```
config global
  config system interface
    edit dmz2
      set vdom accounting
      set ip 10.13.101.100/24
      set allowaccess https ssh
    next
  end
```

Wireless

A wireless interface is similar to a physical interface except it doesn't include a physical connection. FortiWiFi devices allow you to add multiple wireless interfaces that can be available at the same time. On FortiWiFi units, you can configure the device to be either an access point or a wireless client. As an access point, the FortiWiFi unit can have separate SSIDs, each on their own subnet for wireless access. In client mode, the FortiWiFi has only one SSID, and is used as a receiver to allow remote users to connect to the existing network using wireless protocols.

Wireless interfaces also require additional security measures to ensure the session doesn't get hijacked and data tampered with or stolen.

For more information about configuring wireless interfaces see the [FortiOS FortiWiFi and FortiAP Configuration Guide](#).

VLANs

Virtual Local Area Networks (VLANs) multiply the capabilities of a FortiGate, and can also provide added network security. VLANs use ID tags to logically separate devices on a network into smaller broadcast domains. These smaller domains forward packets only to devices that are part of that VLAN domain. This reduces traffic and increases network security. The IEEE 802.1Q standard defines VLANs. All layer-2 and layer-3 devices along a route must be 802.1Q-compliant to support VLANs along that route.

A Local Area Network (LAN) is a group of connected computers and devices that are arranged into network broadcast domains. A LAN broadcast domain includes all the computers that receive a packet broadcast from any computer in that broadcast domain. A switch automatically forwards the packets to all of its ports. In contrast, routers don't automatically forward network broadcast packets. This means routers separate broadcast domains. If a network has only switches and no routers, that network is considered one broadcast domain, no matter how

large or small it is. Smaller broadcast domains are more efficient because fewer devices receive unnecessary packets. They are more secure as well because a hacker reading traffic on the network will have access to only a small portion of the network instead of the entire network's traffic.

VLANs reduce the size of the broadcast domains by only forwarding packets to interfaces that are part of that VLAN or part of a VLAN trunk link. Trunk links form switch-to-switch or switch-to-router connections, and forward traffic for all VLANs. This enables a VLAN to include devices that are part of the same broadcast domain, but physically distant from each other.

VLAN ID tags consist of a 4-byte frame extension that switches and routers apply to every packet sent and received in the VLAN. Workstations and desktop computers, which are commonly originators or destinations of network traffic, aren't an active part of the VLAN process. All of the VLAN tagging and tag removal is done after the packet has left the computer.

A FortiGate that doesn't have VDOMs enabled can have a maximum of 255 interfaces in transparent operating mode. The same is true for any single VDOM. In NAT mode, the number can range from 255 to 8192 interfaces per VDOM, depending on the FortiGate model. These numbers include VLANs, other virtual interfaces, and physical interfaces. To have more than 255 interfaces configured in transparent operating mode, you need to configure multiple VDOMs that enable you to divide the total number of interfaces over all the VDOMs.

One example of an application of VLANs is a company's accounting department. Accounting computers may be located at both main and branch offices. However, accounting computers need to communicate with each other frequently and require increased security. VLANs allow the accounting network traffic to be sent only to accounting computers and to connect accounting computers in different locations as if they were on the same physical subnet.

This guide uses the term "packet" to refer to both layer-2 frames and layer-3 packets.

On a layer-2 switch, you can have only one VLAN subinterface per physical interface, unless that interface is configured as a trunk link. Trunk links can transport traffic for multiple VLANs to other parts of the network.

You can add multiple VLANs to the same physical interface on a FortiGate. However, VLAN subinterfaces added to the same physical interface can't have the same VLAN ID or have IP addresses on the same subnet. You can add VLAN subinterfaces with the same VLAN ID to different physical interfaces.

Creating VLAN subinterfaces with the same VLAN ID doesn't create an internal connection between them. For example, a VLAN ID of 300 on port1 and VLAN ID of 300 on port2 are allowed, but they aren't connected. Their relationship is the same as between any two FortiGate network interfaces.

FortiGate interfaces can't have overlapping IP addresses, the IP addresses of all interfaces must be on different subnets. This rule applies to both physical interfaces and to virtual interfaces, such as VLAN subinterfaces. Each VLAN subinterface must be configured with its own IP address and netmask. This rule helps prevent a broadcast storm or other similar network problems.

The following example shows how to add a VLAN, called `vlan_accounting`, on the FortiGate internal interface with an IP address of 10.13.101.101.

To add a VLAN - GUI:

1. Go to **Network > Interfaces**.
2. Select **Create New** and click on **Interface**.
The **Type** is set to VLAN, by default.
3. Enter a name for the **VLAN** to `vlan_accounting`.
4. Select the **Internal** interface.

5. Enter the VLAN ID.

The VLAN ID is a number between 1 and 4094 that allow groups of IP addresses with the same VLAN ID to be associated together.

6. Select the Addressing Mode of Manual.**7. Enter the IP address for the port of 10.13.101.101/24.****8. Set the Administrative Access to HTTPS and SSH.****9. Select OK.****To add a VLAN - CLI:**

```
config system interface
edit VLAN_1
set interface internal
set type vlan
set vlanid 100
set ip 10.13.101.101/24
set allowaccess https ssh
next
end
```

VLANs in NAT mode

In NAT mode, the FortiGate functions as a layer-3 device. In this mode, the FortiGate controls the flow of packets between VLANs, but can also remove VLAN tags from incoming VLAN packets. The FortiGate unit can also forward untagged packets to other networks, such as the Internet.

In NAT mode, the FortiGate supports VLAN trunk links with IEEE 802.1Q-compliant switches, or routers. The trunk link transports VLAN-tagged packets between physical subnets or networks. When you add VLAN sub-interfaces to the FortiGate physical interfaces, the VLANs have IDs that match the VLAN IDs of packets on the trunk link. The FortiGate directs packets with VLAN IDs to sub-interfaces with matching IDs.

You can define VLAN sub-interfaces on all FortiGate physical interfaces. However, if multiple virtual domains are configured on the FortiGate, you will have access to only the physical interfaces on your virtual domain. The FortiGate can tag packets leaving on a VLAN subinterface. It can also remove VLAN tags from incoming packets and add a different VLAN tag to outgoing packets.

Normally in VLAN configurations, the FortiGate device's internal interface is connected to a VLAN trunk, and the external interface connects to an Internet router that isn't configured for VLANs. In this configuration, the FortiGate can apply different policies for traffic on each VLAN interface connected to the internal interface, which results in less network traffic and better security.

Adding VLAN subinterfaces

A VLAN subinterface, also called a VLAN, is a virtual interface on a physical interface. The subinterface allows routing of VLAN tagged packets using that physical interface, but it's separate from any other traffic on the physical interface.

Adding a VLAN subinterface includes configuring:

- a physical interface
- an IP address and netmask
- a VLAN ID
- a VDOM

Physical interface

The term VLAN subinterface correctly implies the VLAN interface isn't a complete interface by itself. You add a VLAN subinterface to the physical interface that receives VLAN-tagged packets. The physical interface can belong to a different VDOM than the VLAN, but it must be connected to a network router that is configured for this VLAN. Without that router, the VLAN won't be connected to the network, and VLAN traffic won't be able to access this interface. The traffic on the VLAN is separate from any other traffic on the physical interface.

When you are working with interfaces on a FortiGate, use the **Column Settings** on the Interface display to make sure the information you need is displayed. When working with VLANs, it's useful to position the **VLAN ID** column close to the IP address. If you're working with VDOMs, including the **Virtual Domain** column as well will help you troubleshoot problems more quickly.

To view the Interface display, go to **Network > Interfaces**.

IP address and netmask

FortiGate interfaces can't have overlapping IP addresses. The IP addresses of all interfaces must be on different subnets. This rule applies to both physical and virtual interfaces, such as VLAN subinterfaces. Each VLAN subinterface must be configured with its own IP address and netmask pair. This rule helps prevent a broadcast storm or other similar network problems.

If you're unable to change your existing configurations to prevent IP overlap, enter the CLI command `config system settings and set allow-subnet-overlap enable` to allow IP address overlap. If you enter this command, multiple VLAN interfaces can have an IP address that's part of a subnet used by another interface. This command is recommended for advanced users only.

VLAN ID

The VLAN ID is part of the VLAN tag added to the packets by VLAN switches and routers. The VLAN ID is a number between 1 and 4094 that allow groups of IP addresses with the same VLAN ID to be associated together. VLAN ID 0 is used only for high priority frames, and 4095 is reserved.

All devices along a route must support the VLAN ID of the traffic along that route. Otherwise, the traffic will be discarded before reaching its destination. For example, if your computer is part of VLAN_100 and a co-worker on a different floor of your building is also on the same VLAN_100, you can communicate with each other over VLAN_100, only if all the switches and routers support VLANs and are configured to pass along VLAN_100 traffic properly. Otherwise, any traffic you send to your co-worker will be blocked or won't be delivered.

VDOM

If VDOMs are enabled, each VLAN subinterface must belong to a VDOM. This rule also applies for physical interfaces.

Interface-related CLI commands require a VDOM to be specified, regardless of whether a FortiGate has VDOMs enabled.

VLAN subinterfaces on separate VDOMs can't communicate directly with each other. In this situation, the VLAN traffic must exit the FortiGate and re-enter the unit, passing through firewalls in both directions. This situation is the same for physical interfaces.

A VLAN subinterface can belong to a different VDOM than the physical interface it is part of. This is because the traffic on the VLAN is handled separately from the other traffic on that interface. This is one of the main strengths of VLANs.

The following procedure will add a VLAN subinterface called `VLAN_100` to the FortiGate internal interface with a VLAN ID of 100. It will have an IP address and netmask of `172.100.1.1/255.255.255.0`, and allow HTTPS and PING administrative access. Note that in the CLI, you must enter “`set type vlan`” before setting the `vlanid`, and that the `allowaccess` protocols are lower case.

To add a VLAN subinterface in NAT mode - GUI:

1. If **Current VDOM** appears at the bottom left of the screen, select **Global** from the list of VDOMs.
2. Go to **Network > Interfaces**.
3. Select **Create New** to add a VLAN subinterface.
4. Enter the following:

VLAN Name	VLAN_100
Type	VLAN
Interface	internal
VLAN ID	100
Addressing Mod	Manual
IP/Netmask	172.100.1.1/255.255.255.0
Administrative Access	HTTPS, PING, TELNET

5. Select **OK**.

To view the new VLAN subinterface, select the expand arrow next to the parent physical interface (the internal interface). This will expand the display to show all VLAN subinterfaces on this physical interface. If there is no expand arrow displayed, there are no subinterfaces configured on that physical interface.

For each VLAN, the list displays the name of the VLAN, and, depending on column settings, its IP address, the Administrative access you selected for it, the VLAN ID number, and which VDOM it belongs to if VDOMs are enabled.

To add a VLAN subinterface in NAT mode - CLI:

```
config system interface
  edit VLAN_100
    set interface internal
    set type vlan
    set vlanid 100
    set ip 172.100.1.1 255.255.255.0
    set allowaccess https ping
  next
end
```

Configuring security policies and routing

Once you create a VLAN subinterface on a FortiGate, you need to configure security policies and routing for that VLAN. Without these, the FortiGate won't pass VLAN traffic to its intended destination. Security policies direct traffic through the FortiGate between interfaces. Routing directs traffic across the network.

Configuring security policies

Security policies permit communication between the FortiGate device's network interfaces, based on source and destination IP addresses. Interfaces that communicate with the VLAN interface need security policies to permit traffic to pass between them and the VLAN interface.

Each VLAN needs a security policy for each of the following connections the VLAN will be using:

- From this VLAN to an external network
- From an external network to this VLAN
- From this VLAN to another VLAN in the same virtual domain on the FortiGate
- From another VLAN to this VLAN in the same virtual domain on the FortiGate

The packets on each VLAN are subject to antivirus scans and other security profiles measures as they pass through the FortiGate.

Configuring routing

As a minimum, you need to configure a default static route to a gateway with access to an external network for outbound packets. In more complex cases, you must configure different static or dynamic routes based on packet source and destination addresses.

As with firewalls, you must configure routes for VLAN traffic. VLANs need routing and a gateway configured to send and receive packets outside their local subnet just as physical interfaces do. The type of routing you configure, static or dynamic, will depend on the routing used by the subnet and interfaces you're connecting to. Dynamic routing can be routing information protocol (RIP), border gateway protocol (BGP), open shortest path first (OSPF), or multicast.

If you enable SSH, PING, HTTPS and HTTP on the VLAN, you can use those protocols to troubleshoot your routing and test that it's properly configured. Enabling logging on the interfaces and using CLI diagnose commands, such as `diagnose sniff packet <interface_name>`, can also help locate any possible configuration or hardware issues.

VLANs in transparent mode

In transparent mode, a FortiGate behaves like a layer-2 bridge but it can still provide services such as antivirus scanning, web filtering, spam filtering, and intrusion protection to traffic. There are some limitations in transparent mode because you can't use SSL VPN, PPTP/L2TP VPN, DHCP server, or easily perform NAT on traffic. The limits in transparent mode apply to IEEE 802.1Q VLAN trunks passing through the device.

VLANs and transparent mode

You can insert a FortiGate operating in transparent mode into the VLAN trunk without making changes to your network. In a typical configuration, the FortiGate internal interface accepts VLAN packets on a VLAN trunk from a VLAN switch or router connected to internal network VLANs. The FortiGate external interface forwards VLAN-tagged packets through another VLAN trunk to an external VLAN switch or router and on to external

networks, such as the Internet. You can configure the unit to apply different policies for traffic on each VLAN in the trunk.

To pass VLAN traffic through the FortiGate, add two VLAN subinterfaces with the same VLAN ID, one to the internal interface and the other to the external interface. You then create a security policy to permit packets to flow from the internal VLAN interface to the external VLAN interface. If required, you create another security policy to permit packets to flow from the external VLAN interface to the internal VLAN interface. Typically in transparent mode, you don't permit packets to move between different VLANs. Network protection features, such as spam filtering, web filtering, and anti-virus scanning, are applied through the Security Profiles specified in each security policy, enabling very detailed control over traffic.

When the FortiGate receives a VLAN-tagged packet at a physical interface, it directs the packet to the VLAN subinterface with the matching VLAN ID. The VLAN tag is removed from the packet, and the FortiGate then applies security policies using the same method it uses for non-VLAN packets. If the packet exits the FortiGate through a VLAN subinterface, the VLAN ID for that subinterface is added to the packet and the packet is sent to the corresponding physical interface.

General configuration steps

There are two essential steps to configure a FortiGate to work with VLANs in transparent mode: add VLAN subinterfaces and create security policies.

You can also configure the Security Profiles that manage antivirus scanning, web filtering and spam filtering. For more information about Security profiles, see the [FortiOS Security Profiles Handbook](#).

Add VLAN subinterfaces

The VLAN ID of each VLAN subinterface must match the VLAN ID added by the IEEE 802.1Q-compliant router or switch. The VLAN ID can be any number between 1 and 4094, with 0 being used only for high priority frames and 4095 being reserved. You add VLAN subinterfaces to the physical interface that receives VLAN-tagged packets.

For this example, we're creating a VLAN called `internal_v225` on the internal interface, with a VLAN ID of 225. Administrative access is enabled for HTTPS and SSH. VDOMs aren't enabled.

To add VLAN subinterfaces in transparent mode - GUI:

1. Go to **Network > Interfaces**.
2. Select **Create New** and click on **Interfaces**.
3. Enter the following information and select **OK**.

Name	internal_v225
Type	VLAN
Interface	internal
VLAN ID	225
Administrative Access	Enable HTTPS, and SSH. These are very secure access methods.

The FortiGate adds the new subinterface to the interface that you selected.

Repeat steps 2 and 3 to add additional VLANs. You will need to change the **VLAN ID**, **Name**, and possibly **Interface** when adding additional VLANs.

To add VLAN subinterfaces in transparent mode - CLI:

```

config system interface
  edit internal_v225
    set interface internal
    set vlanid 225
    set allowaccess HTTPS SSH
    set description "VLAN 225 on internal interface"
    set vdom root
  end

```

Create security policies

In transparent mode, the FortiGate performs antivirus and antispam scanning on each VLAN's packets as they pass through the device. You need security policies to permit packets to pass from the VLAN interface where they enter the device to the VLAN interface where they exit the device. If there are no security policies configured, no packets will be allowed to pass from one interface to another.

To add security policies for VLAN subinterfaces - GUI:

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New** to add firewall addresses that match the source and destination IP addresses of VLAN packets.
3. Go to **Policy & Objects > IPv4 Policy** or **Policy & Objects > IPv6 Policy** and select **Create New**.
4. From the **Incoming Interface/Zone** list, select the VLAN interface where packets enter the unit.
5. From the **Outgoing Interface/Zone** list, select the VLAN interface where packets exit the unit.
6. Select the **Source** and **Destination** Address names that you added in step 2.
7. Select **OK**.

To add security policies for VLAN subinterfaces - CLI:

```

config firewall address
  edit incoming_VLAN_address
    set associated-interface <incoming_VLAN_interface>
    set type ipmask
    set subnet <IPv4_address_mask>
  next
  edit outgoing_VLAN_address
    set associated-interface <outgoing_VLAN_interface>
    set type ipmask
    set subnet <IPv4_address_mask>
  next
end
config firewall policy or config firewall policy6
  edit <unused_policy_number>
    set srcintf <incoming_VLAN_interface>
    set srcaddr incoming_VLAN_address
    set destintf <outgoing_VLAN_interface>
    set destaddr outgoing_VLAN_address
    set schedule always
    set service <protocol_to_allow_on_VLAN>
    set action ACCEPT
  next
end

```

VLANs over VXLANs

You can create a Virtual LAN (VLAN) over a Virtual Extensible LAN (VXLAN) tunnel interface. This allows you to keep VLAN tags in VXLAN traffic.

VLAN switching and routing

VLAN switching takes place on the Open Systems Interconnect (OSI) model layer-2, just like other network switching. VLAN routing takes place on the OSI model layer-3. The difference between them is that during VLAN switching, VLAN packets are simply forwarded to their destination. This is different from VLAN routing where devices can open the VLAN packets and change their VLAN ID tags to route the packets to a new destination.

VLAN layer-2 switching

Ethernet switches are layer-2 devices, and generally are 802.1Q compliant. Layer 2 refers to the second layer of the seven layer OSI basic networking model, called the Data Link layer. FortiGate devices act as layer-2 switches or bridges when they are in transparent mode. The devices simply tag and forward the VLAN traffic or receive and remove the tags from the packets. A layer-2 device doesn't inspect incoming packets or change their contents; it only adds or removes tags and routes the packet.

A VLAN can have any number of physical interfaces assigned to it. Multiple VLANs can be assigned to the same physical interface. Typically two or more physical interfaces are assigned to a VLAN, one for incoming and one for outgoing traffic. Multiple VLANs can be configured on one FortiGate, including trunk links.

VLAN layer-3 routing

Routers are layer-3 devices. Layer 3 refers to the third layer of the OSI networking model, the Network layer. FortiGate devices in NAT mode act as layer-3 devices. As with layer 2, FortiGate devices acting as layer-3 devices are 802.1Q-compliant.

The main difference between layer-2 and layer-3 devices is how they process VLAN tags. Layer-2 switches just add, read, and remove the tags. They don't alter the tags or do any other high-level actions. Layer-3 routers not only add, read, and remove tags but also analyze the data frame and its contents. This analysis allows layer-3 routers to change the VLAN tag if it's appropriate and send the data frame out on a different VLAN.

In a layer-3 environment, the 802.1Q-compliant router receives the data frame and assigns a VLAN ID. The router then forwards the data frame to other members of the same VLAN broadcast domain. The broadcast domain can include local ports, layer-2 devices and layer-3 devices, such as routers and firewalls. When a layer-3 device receives the data frame, the device removes the VLAN tag and examines its contents to decide what to do with the data frame. The layer-3 device considers:

- Source and destination addresses
- Protocol
- Port number

The data frame may be forwarded to another VLAN, sent to a regular non-VLAN-tagged network or just forwarded to the same VLAN as a layer-2 switch would do. Or, the data frame may be discarded if the proper security policy has been configured to do so.

Layer-2 and ARP traffic

By default, FortiGate devices don't pass layer-2 traffic. If there are layer-2 protocols such as IPX, PPTP or L2TP in use on your network, you need to configure the FortiGate interfaces to pass these protocols without blocking. Another type of layer-2 traffic is Address Resolution Protocol (ARP) traffic.

To allow layer 2 protocols - CLI:

```
config system interface
  edit <name_str>
    set l2forward enable
  end
```

where <name_str> is the name of an interface.

If VDOMs are enabled, this command is per VDOM. You must set it for each VDOM that has the problem as follows:

```
config vdom
  edit <vdom_name>
    config system interface
      edit <name_str>
        set l2forward enable
      end
    end
  end
```

If you enable layer-2 traffic, you may experience a problem if packets are allowed to repeatedly loop through the network. This repeated looping, very similar to a broadcast storm, occurs when you have more than one layer-2 path to a destination. Traffic may overflow and bring your network to a halt. You can break the loop by enabling Spanning Tree Protocol (STP) on your network's switches and routers.

STP forwarding

A FortiGate doesn't participate in the Spanning Tree Protocol (STP). STP is an IEEE 802.1 protocol that ensures there are no layer-2 loops on the network. Loops are created when there is more than one route for traffic to take and that traffic is broadcast back to the original switch. This loop floods the network with traffic, reducing available bandwidth to nothing.

If you use a FortiGate in a network topology that relies on STP for network loop protection, you need to make changes to the FortiGate configuration. Otherwise, STP recognizes the FortiGate as a blocked link and forwards the data to another path. By default, the FortiGate blocks STP as well as other non-IP protocol traffic.

Using the CLI, you can enable forwarding of STP and other layer-2 protocols through the interface. In this example, layer-2 forwarding is enabled on the external interface:

```
config system interface
  edit external
    set l2forward enable
    set stpforward enable
  next
end
```

By substituting different commands for `stpforward enable`, you can also allow layer-2 protocols, such as IPX, PPTP, or L2TP, to be used on the network.

STP support for FortiGate models with hardware switches

STP (Spanning Tree Protocol) used to be available only on the old style switch mode for the internal ports. You can now activate STP on the hardware switches found in the newer FortiGate models. These models use a virtual switch to simulate the old switch mode for the internal ports.

To enable STP - CLI:

```
config system interface
  edit lan
    set stp {enable | disable}
  next
end
```

ARP traffic

Address Resolution Protocol (ARP) packets are vital to communication on a network and ARP support is enabled on FortiGate interfaces, by default. Normally, you want ARP packets to pass through a FortiGate, especially if it's sitting between a client and a server or between a client and a router.

ARP traffic can cause problems, especially in transparent mode where ARP packets arriving on one interface are sent to all other interfaces including VLAN subinterfaces. Some layer-2 switches become unstable when they detect the same MAC address originating on more than one switch interface or from more than one VLAN. This instability can occur if the layer-2 switch doesn't maintain separate MAC address tables for each VLAN. Unstable switches may reset and cause network traffic to slow down considerably.

The default ARP timeout value is 5 minutes (300 seconds). ARP entries are usually removed after 5 minutes. However, some conditions can cause ARP entries to remain on the list for a longer period of time. This isn't a value that you can configure. To view the ARP list, enter the `get system arp` CLI command.

Proxy ARP extensions

You can extend the proxy ARP configuration to an IP address range instead of a single IP address. When you configure `proxy-arp`, in addition to setting the IP address, you can also set the `end-ip` address. If you don't set this, the proxy ARP will be a single address, as before. The following is an example CLI configuration, using the new setting:

```
config system proxy-arp
  edit 1
    set interface "internal"
    set ip 192.168.1.100
    set end-ip 192.168.1.102
  next
end
```

Multiple VDOMs solution

By default, physical interfaces are in the root domain. If you don't configure any of your VLANs in the root VDOM, it won't matter how many interfaces are in the root VDOM.

The multiple VDOMs solution is to configure multiple VDOMs on the FortiGate, one for each VLAN. In this solution, you configure one inbound and one outbound VLAN interface in each VDOM. ARP packets aren't forwarded between VDOMs. This configuration limits the VLANs in a VDOM and correspondingly reduces the administration needed per VDOM.

As a result of this configuration, the switches don't receive multiple ARP packets with duplicate MACs. Instead, the switches receive ARP packets with different VLAN IDs and different MACs. Your switches are stable.

However, you shouldn't use the multiple VDOMs solution under any of the following conditions:

- You have more VLANs than licensed VDOMs
- You don't have enough physical interfaces

Instead, use one of two possible solutions, depending on which operation mode you're using:

- In NAT mode, you can use the `vlanforward` CLI command.
- In transparent mode, you can use the `forward-domain` CLI command. But you still need to be careful in some rare configurations.

Vlanforward solution

If you're using NAT mode, the solution is to use the `vlanforward` CLI command for the interface in question. By default, this command is enabled and will forward VLAN traffic to all VLANs on this interface. When disabled, each VLAN on this physical interface can send traffic only to the same VLAN. There is no cross-talk between VLANs, and ARP packets are forced to take one path along the network which prevents the multiple paths problem.

In the following example, `vlanforward` is disabled on port1. All VLANs configured on port1 will be separate and will not forward any traffic to each other.

```
config system interface
  edit port1
    set vlanforward disable
  next
end
```

Forward-domain solution

If you're using transparent mode, the solution is to use the `forward-domain` CLI command. This command tags VLAN traffic as belonging to a particular collision group, and only VLANs tagged as part of that collision group receive that traffic. It's like an additional set of VLANs. By default, all interfaces and VLANs are part of forward-domain collision group 0. The many benefits of this solution include reduced administration, the need for fewer physical interfaces, and the availability of more flexible network solutions.

In the following example, forward-domain collision group 340 includes VLAN 340 traffic on port1 and untagged traffic on port 2. Forward-domain collision group 341 includes VLAN 341 traffic on port 1 and untagged traffic on port 3. All other interfaces are part of forward-domain collision group 0, by default. This configuration separates VLANs 340 and 341 from each other on port 1.

Use the following CLI commands:

```
config system interface
  edit port2
    set forward_domain 340
  next
  edit port3
    set forward_domain 341
  next
  edit port1-340
    set forward_domain 340
    set interface port1
```

```
        set vlanid 340
    next
    edit port1-341
        set forward_domain 341
        set interface port1
        set vlanid 341
    next
end
```

You may experience connection issues with layer-2 traffic, such as ping, if your network configuration has:

- Packets going through the FortiGate in transparent mode more than once
- More than one forwarding domain (such as incoming on one forwarding domain and outgoing on another)
- IPS and AV enabled

Now IPS and AV is applied the first time packets go through the FortiGate, but not on subsequent passes. Applying IPS and AV only to this first pass fixes the network layer-2 related connection issues.

Asymmetric routing

You might discover unexpectedly that hosts on some networks are unable to reach certain other networks. This occurs when request and response packets follow different paths. If a FortiGate recognizes the response packets, but not the requests, it blocks the packets as invalid. Also, if a FortiGate recognizes the same packets repeated on multiple interfaces, it blocks the session as a potential attack.

This is asymmetric routing. By default, a FortiGate blocks packets or drops the session when this happens. You can configure the FortiGate to permit asymmetric routing by using the following CLI commands:

```
config system settings
    set asymroute enable
end
```

If VDOMs are enabled, this command is per VDOM. You must set it for each VDOM that has the problem as follows:

```
config vdom
    edit <vdom_name>
        config system settings
            set asymroute enable
        end
    end
end
```

If this solves your blocked traffic issue, you know that asymmetric routing is the cause. But allowing asymmetric routing is not the best solution, because it reduces the security of your network.

For a long-term solution, it is better to change your routing configuration or change how the FortiGate connects to your network.

If you enable asymmetric routing, antivirus and intrusion prevention systems won't be effective. The FortiGate won't be aware of connections and will treat each packet individually. It will become a stateless firewall.

Configuring IPv4 and IPv6 ICMP traffic inspection

In order for the inspection of asymmetric ICMP traffic not to affect TCP and UDP traffic, you can enable or disable ICMP traffic inspection for traffic being routed asymmetrically for both IPv4 and IPv6.

To configure ICMP traffic inspection, use the following CLI commands:

- IPv4:

```
config system settings
  set asymroute-icmp
end
```

- IPv6:

```
config system settings
  set asymroute6-icmp
end
```

NetBIOS

Computers running Microsoft Windows operating systems that are connected through a network rely on a WINS server to resolve host names to IP addresses. The hosts communicate with the WINS server by using the NetBIOS protocol.

To support this type of network, you need to enable the forwarding of NetBIOS requests to a WINS server. The following example forwards NetBIOS requests on the internal interface for the WINS server located at an IP address of 192.168.111.222.

```
config system interface
  edit internal
    set netbios_forward enable
    set wins-ip 192.168.111.222
  next
end
```

These commands apply only to NAT mode. If VDOMs are enabled, these commands are per VDOM. You must set them for each VDOM that has the problem.

Too many VLAN interfaces

Any virtual domain can have a maximum of 255 interfaces in transparent mode. This includes VLANs, other virtual interfaces, and physical interfaces. NAT mode supports from 255 to 8192 depending on the FortiGate model. This total number of interfaces includes VLANs, other virtual interfaces, and physical interfaces.

A FortiGate may allow you to configure more interfaces than this. However, if you configure more than 255 interfaces, your system will become unstable and, over time, won't work properly. As all interfaces are used, they will overflow the routing table that stores the interface information, and connections will fail. When you try to add more interfaces, an error message will state that the maximum limit has already been reached.

If you see this error message, chances are you already have too many VLANs on your system and your routing has become unstable. To verify, delete a VLAN and try to add it back. If you have too many, you won't be able to add it back on to the system. In this case, you'll need to remove enough interfaces (including VLANs) so that the total number of interfaces drops to 255 or less. After doing this, you should also reboot the FortiGate to clean up its memory and buffers, or you will continue to experience unstable behavior.

To configure more than 255 interfaces on a FortiGate in transparent mode, you have to configure multiple VDOMs, each with many VLANs. However, if you want to create more than the default 10 VDOMs (or a maximum

of 2550 interfaces), you must buy a license for additional VDOMs and the FortiGate must be able to be licensed for more than 10 VDOMs.

With these extra licenses, you can configure up to 500 VDOMs, with each VDOM containing up to 255 VLANs in transparent mode. This is a theoretical maximum of over 127 500 interfaces. However, system resources will quickly get used up before reaching that theoretical maximum. To achieve the maximum number of VDOMs, you need to have top-end hardware with the most resources possible.

In NAT mode, if you have a top-end model, the maximum interfaces per VDOM can be as high as 8192, which is enough for all the VLANs in your configuration.

A FortiGate has limited resources, such as CPU load and memory, that are divided between all configured VDOMs. When running 250 or more VDOMs, you may need to monitor the system resources to ensure there is enough to support the configured traffic processing.

Troubleshooting VLAN issues

Several problems can occur with your VLANs. Since VLANs are interfaces with IP addresses, they behave as interfaces and can have similar problems that you can diagnose with tools, such as ping, traceroute, packet sniffing, and diag debug.

Enhanced MAC VLANs

The media access control (MAC) virtual local area network (VLAN) feature in Linux allows you to configure multiple virtual interfaces with different MAC addresses (and therefore different IP addresses) on a physical interface.

A FortiGate implements an enhanced MAC VLAN which consists of a MAC VLAN with bridge functionality. Because each MAC VLAN has a unique MAC address, virtual IP addresses (VIPs) and IP pools are supported, and you can disable Source Network Address Translation (SNAT) in policies. However, MAC VLAN can't be used in a transparent mode virtual domain (VDOM). In a transparent mode VDOM, a packet leaves an interface with the MAC address of the original source instead of the interface's MAC address. FortiGate solves this limitation by implementing an enhanced version of MAC VLAN, where it adds a MAC table in the MAC VLAN which learns various MAC addresses when traffic passes through.

If you configure a VLAN ID for an enhanced MAC VLAN, it won't join the switch of the underlying interface. When a packet is sent to this interface, a VLAN tag is inserted in the packet, and the packet is sent to the driver of the underlying interface. When the underlying interface receives a packet, if the VLAN ID doesn't match, it won't deliver the packet to this enhanced MAC VLAN interface.

If you use an interface in an enhanced MAC VLAN, you shouldn't use it for other purposes, such as a management interface, HA heartbeat interface, or in transparent VDOMs.

If a physical interface is used by an EMAC VLAN interface, you can't use it in a virtual wire pair.

To configure enhanced MAC VLAN – CLI:

```
config system interface
  edit <interface-name>
    set type emac-vlan
    set vlan-id <VLAN-ID>
    set interface <physical-interface>
```

```

next
end

```

Setting a VLAN ID is optional.

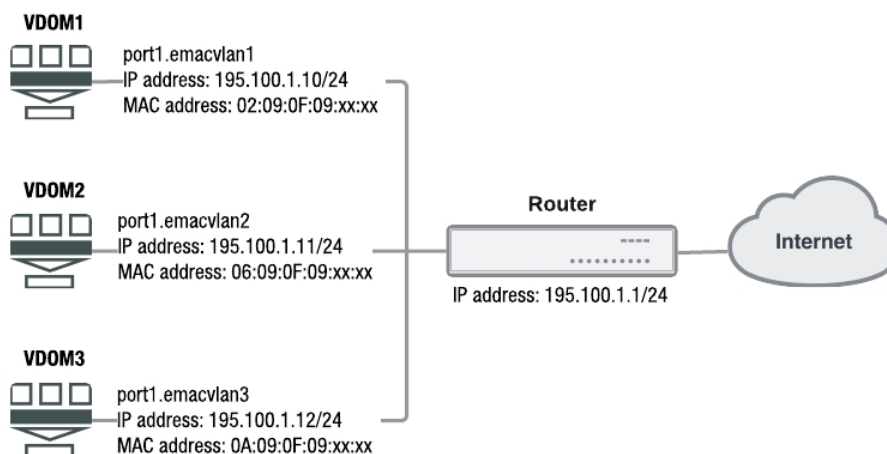

Enhanced MAC VLANs and HA

In high availability (HA) configurations, enhanced MAC VLAN is treated as a physical interface. It's assigned a unique physical interface ID and the MAC table is synchronized to the slaves in the same HA cluster.

Example 1: Enhanced MAC VLAN configuration for multiple VDOMs that use the same interface or VLAN

In this example, a FortiGate is connected, through port 1, to a router that's connected to the Internet. Three VDOMs share the same interface (port 1), which connects to the same router that's connected to the Internet. Three enhanced MAC VLAN interfaces are configured on port 1 for the three VDOMs. The enhanced MAC VLAN interfaces are in the same IP subnet segment and each have unique MAC addresses.

The underlying interface (port 1) can be a physical interface, an aggregate interface, or a VLAN interface on a physical or aggregate interface.

In this scenario, the configuration for enhanced MAC VLAN is the following:

```

config system interface
  edit port1.emacvlan1
    set vdom VDOM1
    set type emac-vlan
    set interface port1
  next
  edit port 1.emacvlan2
    set vdom VDOM2
    set type emac-vlan
    set interface port1
  next
  edit port1.emacvlan3
    set vdom VDOM3
    set type emac-vlan
    set interface port1
  next
end

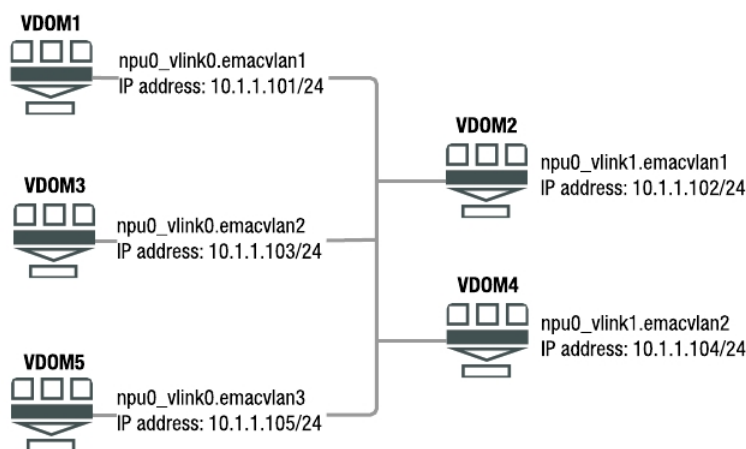

```

end

Example 2: Enhanced MAC VLAN configuration for shared VDOM links among multiple VDOMs

In this example, multiple VDOMs can connect to each other using enhanced MAC VLAN on network processing unit (NPU) virtual link (vlink) interfaces.

Currently, FortiGate VDOM links (npu-vlink) are designed to be peer-to-peer connections and VLAN interfaces on NPU vlink ports use the same MAC address. It's not practical to connect more than 2 VDOMs using NPU vlinks and VLAN interfaces.

In this scenario, the configuration for enhanced MAC VLAN is the following:

```

config system interface
  edit npu0_vlink0.emacvlan1
    set vdom VDOM1
    set type emac-vlan
    set interface npu0_vlink0
  next
  edit npu0_vlink0.emacvlan2
    set vdom VDOM3
    set type emac-vlan
    set interface npu0_vlink0
  next
  edit npu0_vlink1.emacvlan1
    set vdom VDOM2
    set type emac-vlan
    set interface npu0_vlink1
  next
end

```

Example 3: Enhanced MAC VLAN configuration for unique MAC addresses for each VLAN interface on the same physical port

In some networks, a unique MAC address is needed for each VLAN interface when the VLAN interfaces share the same physical port. In this case, the enhanced MAC VLAN interface is used the same way as normal VLAN

interfaces.

To configure this, you use the `set vlanid` command for the VLAN tag.

In this scenario, the configuration for enhanced MAC VLAN is the following:

```
config system interface
  edit interface-name
    set type emac-vlan
    set vlanid <VLAN-ID>
    set interface <physical-interface>
  end
```

Virtual wire pairs

A virtual wire pair logically binds two physical interfaces on a FortiGate, usually an internal and an external interface, together so that all traffic that one of the interfaces in a virtual wire pair accepts can exit the FortiGate only through the other interface in the virtual wire pair, and only if allowed by a virtual wire pair firewall policy. Traffic that arrives on other interfaces can't be routed to interfaces in a virtual wire pair.

The interfaces in a virtual wire pair don't have IP addresses, which means you can configure a virtual wire pair in your network without making any network changes. You can create more than one virtual wire pair on a FortiGate.

You can configure virtual wire pairs on a FortiGate that's running in either transparent or NAT modes. A virtual wire pair supports transparent mode between two interfaces without requiring you to change the FortiGate from NAT to Transparent mode.

If a physical interface is used by an EMAC VLAN interface, you can't use it in a virtual wire pair.

To configure a virtual wire pair - GUI:

Interfaces that you use for administrative access can't be used in a virtual wire pair. If you want to use an interface that you use for administrative access in a virtual wire pair, make sure you configure a different interface to allow administrative access before you create the virtual wire pair.

If the interfaces you want to use in a virtual wire pair are part of a switch, such as the default **lan** interface, you need to remove them from the switch before they can be added to the virtual wire pair.

1. Go to **Network > Interfaces** and select **Create New > Virtual Wire Pair**.
2. In the **Name** field, type a name for the virtual wire pair.
3. In the **Interface Members** field, select the interfaces that you want to add to the virtual wire pair.
4. If you want to enable wildcard VLANs for the virtual wire pair, enable **Wildcard VLAN**.
5. Select **OK**.

To configure a virtual wire pair policy - GUI:

1. Go **Policy & Objects > IPv4 Virtual Wire Pair Policy**.
2. Select a virtual wire pair in the upper right-hand corner of the screen, and select **Create New**.
3. In the **Name** field, type a name for the virtual wire pair policy.
4. In the **Virtual Wire Pair** field, select the direction that traffic is allowed to flow.
5. Configure other firewall options, as needed.
6. Select **OK**.
7. If necessary, create a second virtual wire pair policy to allow traffic to flow in the opposite direction.

Traffic can now flow through the FortiGate using the virtual wire pair. You can go to **FortiView > Policies** to see traffic flowing through both policies.

The **IPv4 Virtual Wire Pair Policy** menu item in the GUI appears only when you have created at least one virtual wire pair.

Wildcard VLANs for virtual wire pairs

Although you can't add virtual local area networks (VLANs) to virtual wire pairs, you can enable wildcard VLANs for a virtual wire pair. Doing this allows all VLAN-tagged traffic to pass through a virtual wire pair if a virtual wire pair firewall policy allows the traffic.

To enable wildcard VLANs for a virtual wire pair, enable the **Wildcard VLAN** option when you create a virtual wire pair.

VLAN filters for virtual wire pairs

After you enable wildcard VLANs, if you don't want a virtual wire pair policy to allow all VLAN traffic, you can specify VLAN filters. A VLAN filter allows only the VLANs in the filter and drops traffic with other VLAN tags. VLAN filters don't affect traffic that isn't VLAN-tagged. You configure VLAN filters using the CLI.

You can add a VLAN filter to a virtual wire pair to apply the filter to all traffic that the virtual wire pair accepts. You can also add a VLAN filter to a virtual wire pair firewall policy to apply more specific VLAN filtering only to the traffic that the policy accepts.

To configure VLAN filters for wildcard VLANs - CLI:

```
config system virtual-wire-pair
  edit <vwp-name>
    set member <vwp-interface1-name> <vwp-interface2-name>
    set wildcard-vlan enable
    set vlan-filter <VLAN-range-list>
  next
end

config firewall policy
  edit <policy-ID>
    set vlan-filter <VLAN-range-list>
  next
end
```

The `vlan-filter` option is only available for policies on virtual wire pairs that have the wildcard VLAN option enabled.

Botnet and command-and-control protection

You can configure botnet and command-and-control traffic protection, in a FortiGate GUI or CLI.

To configure botnet scans on an interface - GUI:

Select the **Scan Outgoing Connections to Botnet Sites** option on the **Interfaces** page. The options are **Disable**, **Block**, and **Monitor**.

To configure botnet scans on an interface - CLI:

```
config system interface
  edit <interface>
    set scan-botnet-connections {disable | block | monitor}
  next
end
```

You can also enable the scanning of botnet and command-and-control traffic in the following policies:

To enable botnet scans in firewall policies - CLI:

```
config firewall policy
  edit <policy ID>
    set scan-botnet-connections {disable | block | monitor}
  next
end
```

To enable botnet scans in firewall explicit proxy policies - CLI:

```
config firewall explicit-proxy-policy
  edit <policy ID>
    set scan-botnet-connections {disable | block | monitor}
  next
end
```

To enable botnet scans in firewall interface policies - CLI:

```
config firewall interface-policy
  edit <policy ID>
    set scan-botnet-connections {disable | block | monitor}
  next
end
```

To enable botnet scans for firewall sniffer - CLI:

```
config firewall sniffer
  edit <policy ID>
    set scan-botnet-connections {disable | block | monitor}
  next
end
```

DNS

A Domain Name System (DNS) server is a public service that converts symbolic node names to IP addresses. A DNS server implements the protocol. In simple terms, it acts as a phone book for the Internet. A DNS server matches domain names with their computer IP addresses. This allows you to use readable locations, such as `fortinet.com`, when you browse the Internet. FortiOS supports DNS configuration for both IPv4 and IPv6 addressing.

FortiGate includes default DNS server addresses. However, you should change these addresses to ones that your Internet Service Provider (ISP) provides. The defaults are DNS proxies and are not as reliable as those from your ISP.

Within FortiOS, there are two DNS configuration options. Each option provides a specific service and both options can work together to provide a complete DNS solution.

DNS settings

You configure basic DNS queries on interfaces that connect to the Internet. When a user requests a website, FortiGate looks to the configured DNS servers to provide the IP address of the website in order to know which server to contact to complete the transaction.

You configure DNS server addresses by selecting **Network > DNS**, and then specifying the DNS server addresses. These addresses are typically supplied by your ISP. If you have local Microsoft domains on the network, you can enter a domain name in the **Local Domain Name** field.

In a situation where all three fields are configured, FortiGate first looks to the local domain. If no match is found, FortiGate sends a request to the external DNS servers.

If virtual domains (VDOM) are enabled, you create a DNS database in each VDOM. All of the interfaces in a VDOM share the DNS database in that VDOM.

Additional DNS CLI configuration

Additional DNS configuration options are available in the CLI, using the `config system dns` command. Within this command, you can also set the following commands:

Command	Description
<code>dns-cache-limit</code>	Set how many DNS entries are stored in the cache. Entries that remain in the cache provide a quicker response to requests than going out to the Internet to get the same information.
<code>dns-cache-ttl</code>	Set how long entries remain in the cache, in seconds. Possible values are 60 to 86400 (default is 24 hours).
<code>cache-notfound-responses</code>	When you enable this, any DNS requests that are returned with NOT FOUND can be stored in the cache.
<code>source-ip</code>	Define a dedicated IP address for communications with the DNS server.

DDNS

If your ISP changes your external IP address on a regular basis, and you have a static domain name, you can configure the external interface to use a dynamic DNS (DDNS) service. This ensures that external users and customers can always connect to your company firewall. If you have a FortiGuard subscription, you can use FortiGuard as the DDNS server.

You can configure FortiGuard as the DDNS server, in the FortiGate GUI or CLI.

To configure FortiGuard as the DDNS server in the FortiGate GUI, select **Network > DNS** and enable **FortiGuard DDNS**. Then select the interface with the dynamic connection, which DDNS server you have an account with, your domain name, and account information. If your DDNS server isn't on the list, there is a generic option where you can provide your DDNS server information.

To configure FortiGuard as the DDNS server - CLI:

```
config system fortiguard
    set ddns-server-ip
    set ddns-server-port
end
```

If you don't have a FortiGuard subscription or want to use a different DDNS server, you can configure DDNS in the CLI. You can configure a DDNS for each interface. Only the first configured port appears in the FortiGate GUI. Additional commands vary depending on the DDNS server you select. Use the following CLI commands:

```
config system ddns
    edit <DDNS_ID>
        set monitor-interface <external_interface>
        set ddns-server <ddns_server_selection>
    next
end
```

Configuring FortiGate to refresh DDNS IP addresses

You can configure FortiGate to refresh DDNS IP addresses. FortiGate periodically checks the DDNS server that is configured.

To configure FortiGate to refresh DDNS IP addresses - CLI:

```
config system ddns
    edit <1>
        set ddns-server FortiGuardDDNS
        set use-public-ip enable
        set update-interval seconds
    next
end
```

The possible values for update-interval are 60 to 2592000 seconds, and the default is 300 seconds.

TLS support for DDNS updates

When cleartext is disabled, FortiGate uses the SSL connection to send and receive Dynamic DNS services (DDNS) updates.

To disable cleartext - CLI:

```
config system ddns
    set clear-text disable
end
```

You can also set the ssl-certificate name in the same location, using the following command:

```
set ssl-certificate <cert_name>
```

DDNS update override for DHCP

DHCP server has an override command option that allows DHCP server communications to go through DDNS to perform updates for the DHCP client. This enforces a DDNS update of the AA field every time, even if the DHCP client does not request it. This allows the support of the allow/ignore/deny client-updates options.

To enable DDNS update override - CLI:

```
config system dhcp server
    edit <0>
        set ddns-update_override enable
    next
end
```

FortiDDNS registration to a public IP address

Fortinet's Dynamic DNS services (FortiDDNS) can be registered to a public IP address even if the FortiGate model doesn't have any physical interfaces on the Internet. This applies to when the FortiGate is behind other networking devices that are employing NAT. You can configure this in the GUI and the CLI.

DNS servers

You can also create local DNS servers for your network. Depending on your requirements, you can manually maintain your entries (master DNS server) or use it as a jumping point, where the server refers to an outside source (slave DNS server). A local master DNS server works similarly to the DNS server addresses configured in **Network > DNS**, but you must manually add all entries. This allows you to add a local DNS server to include specific URL and IP address combinations.

The DNS server options are not visible in the FortiGate GUI, by default. To enable the server, select **System > Feature Visibility**, select **DNS Database**, and select **Apply**.

While a master DNS server is an easy method to include regularly used addresses to save on going to an outside DNS server, it isn't recommended to make it the authoritative DNS server. IP addresses may change and maintaining any type of list can become labor-intensive.

It's best to use a FortiGate master DNS server for local services. For example, a company has a web server in their DMZ that internal users (employees) and external users (customers or remote employees) access. When internal users access a website, a request for the website is sent out to the DNS server on the Internet, which then returns an IP address or virtual IP address. After the company configures an internal DNS server, the same website request is resolved internally to the internal web server IP address. This minimizes inbound and outbound traffic, and access time.

As a slave DNS server, a FortiGate refers to an external or alternate source as a way to obtain the URL and IP address combination. This is useful if there is a master DNS server for a large company, where a list is maintained. Satellite offices can then connect to the master DNS server to obtain the correct addressing.

The DNS server entries don't allow CNAME entries, as per [RFC 1912](#), section 2.4.

Configure a master DNS server - GUI:

1. Select **Network > DNS Servers**, and select **Create New** for **DNS Database**.
2. Select the **Type** of **Master**.
3. Select the **View** as **Shadow**.
4. The view is the accessibility of the DNS server. Selecting **Public**, external users can access, or use, the DNS server. Selecting **Shadow**, only internal users can use it.
5. Enter the **DNS Zone**, for example, `WebServer`.
6. Enter the domain name for the zone, for example `example.com`.
7. Enter the hostname of the DNS server, for example, `Corporate`.
8. Enter the contact address for the administrator, for example, `admin@example.com`.
9. Set **Authoritative** to **Disable**.
10. Select **OK**.
11. Enter the DNS entries for the server by selecting **Create New**.
12. Select the **Type**, for example, **Address (A)**.
13. Enter the **Hostname**, for example `web.example.com`.
14. Enter the remaining information, which varies depending on the **Type** selected.
15. Select **OK**.

Configure a master DNS server - CLI:

```
config system dns-database
  edit WebServer
    set domain example.com
    set type master
    set view shadow
    set ttl 86400
    set primary-name corporate
    set contact admin@example.com
    set authoritative disable
    config dns-entry
      edit 1
        set hostname web.example.com
        set type A
        set ip 192.168.21.12
        set status enable
      next
    next
  next
end
```

Configuring a recursive DNS

You can set an option to ensure this type of DNS server isn't the authoritative server. When configured, a FortiGate checks its internal DNS server (master or slave). If the request can't be fulfilled, it will look to the external DNS servers. This is known as a split DNS configuration.

You can also have a FortiGate look to an internal server if the master or slave doesn't fulfill the request, using the following CLI commands:

```
config system dns-database
  edit example.com
    ...
    set view shadow
  next
end
```

For this behavior to work completely, you must set the DNS query for the external interface to be recursive.

To configure a recursive DNS - GUI:

1. Go to **Network > DNS Servers**, and select **Create New** for **DNS Service on Interface**.
2. Select the **Interface**.
3. Select the **Mode** to **Recursive**.
4. Select **OK**.

To configure a recursive DNS - CLI:

```
config system dns-server
  edit wan1
    set mode recursive
  next
end
```

Configuring IPv6 Router Advertisement options for DNS configuration

FortiGate supports the following RFC 6106 IPv6 Router Advertisement options:

- Obtaining DNS search list options from upstream DHCPv6 servers
- Sending the DNS search list through Router Advertisement
- Sending the DNS search list through the FortiGate DHCP server
- Sending DNS search list option to downstream clients with Router Advertisements that use a static prefix (FortiOS version 5.6.1 and later)
- Sending recursive DNS server option to downstream clients with Router Advertisements that use a static prefix (FortiOS version 5.6.1 and later)

To obtain the DNS search list options from upstream DHCPv6 servers - CLI:

```
config system interface
  edit wan1
    config ipv6
      set dhcp6-prefix-delegation enable
    next
  next
end
```

```
end
```

To send DNS search lists through Router Advertisement - CLI:

```
config system interface
edit port 1
config IPv6
set ip6-address 2001:10::/64
set ip6-mode static
set ip6-send-adv enable
config ip6-delegated-prefix-list
edit 1
set upstream-interface WAN
set subnet 0:0:0:11::/64
set autonomous-flag enable
set onlink-flag enable
next
next
next
end
```

To send the DNS search lists through the FortiGate DHCP server - CLI:

You can use the `dns-search-list delegated` command to send DNS search list option to downstream clients with Router Advertisements that use a static prefix.

```
config system dhcp6 server
edit 1
set interface port2
set upstream-interface WAN
set ip-mode delegated
set dns-service delegated
set dns-search-list delegated
set subnet 0:0:0:12::/64
next
end
```

To send DNS search list option to downstream clients with Router Advertisements that use a static prefix - CLI:

You can use the `set dnssl <DNS search list option>` command to send DNS search list option to downstream clients with Router Advertisements that use a static prefix.

```
config system interface
edit port1
config ipv6
config ip6-prefix-list
edit <2001:db8::/64>
set autonomous-flag enable
set onlink-flag enable
set rdns 2001:1470:8000::66 2001:1470:8000::72
set dnssl <DNS search list option>
next
next
next
next
end
```

To send recursive DNS server option to downstream clients with Router Advertisements that use a static prefix - CLI:

You can use the `set rdns <recursive DNS search option>` command to send Recursive DNS server option to downstream clients with Router Advertisements that use a static prefix.

```
config system interface
  edit port1
    config ipv6
      config ip6-prefix-list
        edit <2001:db8::/64>
          set autonomous-flag enable
          set onlink-flag enable
          set rdns 2001:1470:8000::66 2001:1470:8000::72
          set dnssl <DNS search list option>
        next
      next
    next
  next
end
```

Internet services

The Internet Service Database (ISDB) is a database that contains a list of IP addresses, IP protocols, and port numbers that are used by the most common Internet services.

The IP Reputation Database (IRDB) is a database that's populated by the FortiGuard IP Reputation Service which aggregates malicious source IP data from the Fortinet distributed network of threat sensors and other global sources that collaborate to provide up-to-date threat intelligence about hostile sources. You can select categories, such as Proxy IP, Spam, and TOR Exit Node, to see specific information about each category.

A FortiGate regularly updates new versions of both the ISDB and IRDB from FortiGuard.

To view the ISDB - GUI:

1. Go to **Policy & Objects > Internet Service Database**.
2. In the **Name** column, expand **Internet Service Database**.

To view the IRDB - GUI:

1. Go to **Policy & Objects > Internet Service Database**.
2. In the **Name** column, expand **IP Reputation Database**.

You can use Internet services as a source in firewall policies. For more information, see the [FortiOS Firewall Handbook](#). You can also use Internet services as a source and destination in traffic shaping policies. For more information, see the [FortiOS Traffic Shaping Handbook](#).

Advanced static routing

Advanced static routing includes features and concepts that are used in more complex networks.

Routing concepts

Many routing concepts apply to static routing. However, without first understanding these basic concepts, it's difficult to understand the more complex dynamic routing.

Routing in VDOMs

Routing on FortiGate devices is configured per VDOM. This means if VDOMs are enabled, you must enter a VDOM to do any routing configuration. This allows each VDOM to operate independently, with its own default routes and routing configuration.

In this guide, the procedures assume that the FortiGate has VDOMs disabled. This is stated in the assumptions for the examples. If the FortiGate has VDOMs enabled, you'll need to perform the following steps in addition to the procedure steps.

To route in VDOMs - GUI:

Select the VDOM that you want to view or configure at the bottom of the main menu.

To route in VDOMs - CLI:

Before you follow any CLI routing procedures with VDOMs enabled, enter the following commands. For this example, it's assumed that you'll be working in the root VDOM. Change root to the name of your selected VDOM as needed.

```
config vdom
edit root
```

Following these commands, you can enter any routing CLI commands, as normal.

Default route

The default route is used if there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

All routers, including FortiGate devices, are shipped with default routes in place. This allows you to set up and become operational more quickly. Beginner administrators can use the default route settings until a more advanced configuration is needed.

Adding or editing a static route

1. Go to **Network > Static Routes** and select **Create New**.
2. Enter the following information and select **OK**.

Destination IP/Mask	Enter the destination IP address and netmask. A value of 0 . 0 . 0 . 0 / 0 . 0 . 0 . 0 is universal.
Gateway	Enter the gateway IP address.
Interface	Select the name of the interface that the static route will connect through.
Administrative Distance	Enter the distance value, which will affect which routes are selected first by different protocols for route management or load balancing. The default is 10.
Advanced Options	Optionally, expand Advanced Options and enter a Priority , which will artificially weight the route during route selection. The higher the priority number, the less likely the route is to be selected over other routes. The default is 0.

Enabling or disabling individual static routes

You can enable or disable individual static routes.

To configure IPv4 static routes - CLI:

```
config router static
  edit <sequence number>
    set status {enable | disable}
  next
end
```

To configure IPv6 static routes - CLI:

```
config router static6
  edit <sequence number>
    set status {enable | disable}
  next
end
```

Configuring FQDNs as a destination address in static routes

You can configure FQDN firewall addresses as destination addresses in a static route, using either the GUI or the CLI.

In the GUI, to add an FQDN firewall address to a static route in the firewall address configuration, enable the **Static Route Configuration** option. Then, when you configure the static route, set **Destination** to **Named Address**.

In the CLI, use the following CLI commands:

First, configure the firewall FQDN address:

```
config firewall address
  edit 'Fortinet-Documentation-Website'
    set type fqdn
    set fqdn docs.fortinet.com
    set allow-routing enable
```

Next, add the FQDN address to a static route.

```
config router static
  edit 0
    set dstaddr Fortinet-Documentation-Website
    ...
  end
```

Routing table

When two computers are directly connected, there's no need for routing because each computer knows exactly where to find the other computer, and they communicate directly.

Networking computers allows many computers to communicate with each other. This requires each computer to have an IP address to identify its location to the other computers. This is much like a mailing address, where you won't receive your postal mail at home if you don't have an address for people to send mail to. The routing table on a computer is much like an address book used to mail letters to people, where the routing table maintains a list of how to reach computers. Routing tables may also include information about the quality of service (QoS) of the route, and the interface associated with the route if the device has multiple interfaces.

Looking at routing as delivering letters is more simple than reality. In reality, routers lose power or have bad cabling, network equipment is moved without warning, and other such events happen that prevent static routes from reaching their destinations. When any changes, such as these, happen along a static route, traffic can no longer reach the destination and the route goes down. Dynamic routing can address these changes to ensure that traffic still reaches its destination. The process of realizing there's a problem, backtracking, and finding a route that is operational, is called convergence. If there's fast convergence in a network, users won't even know that re-routing is taking place.

The routing table for any device on the network has a limited size. For this reason, routes that aren't used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes, which are the routes that have the best chance of being reused. Another method that's used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Routing tables are also used in unicast reverse path forwarding (uRPF). In uRPF, the router not only looks up the destination information but it also looks up the source information to ensure that it exists. If there's no source to be found, that packet is dropped because the router assumes it's an error or an attack on the network.

The routing table is used to store routes that are learned. The routing table for any device on the network has a limited size. For this reason, routes that aren't used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes, which are the routes that have the best chance of being reused. Another method used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Viewing the routing table

You can view the routing table in the FortiGate GUI. By default, all routes are displayed in the Routing Monitor list. The default static route is defined as 0.0.0.0/0, which matches the destination IP address of "any/all" packets.

To display the routes in the routing table, go to **Monitor > Routing Monitor**. Select **Static & Dynamic** to view the routes.

You can also monitor policy routes. Select **Policy** to list the active policy routes on the FortiGate and view information about them. The active policy routes include policy routes that you create, SD-WAN rules, and Internet service static routes. It also supports downstream devices in the Security Fabric.

The following figure show an example of the static and dynamic routes in the Routing Monitor list:

Refresh	Route Lookup	Edit Route	Create Address	Static & Dynamic Policy	
IP Version	Type	Network	Gateway IP	Interfaces	Distance
4	Static	0.0.0.0/0	172.25.176.1	port1	10
4	Connected	172.25.176.0/24	0.0.0.0	port1	0
6	Connected	::1/128	::	root	0
6	System	ff00::8	::	port3	0

The following figure show an example of the policy routes in the Routing Monitor list:

Field	Description
IP Version	Shows whether the route is IPv4 or IPv6. IPv6 routes are displayed only if IPv6 is enabled in the FortiGate GUI.
Type	<p>The type values assigned to FortiGate routes (Static, Connected, RIP, OSPF, or BGP).</p> <ul style="list-style-type: none"> • All: All routes recorded in the routing table • Connected: All routes associated with direct connections to FortiGate interfaces • Static: The static routes that have been added to the routing table manually • RIP: All routes learned through RIP. For more information, see "RIP" on page 2110. • RIPNG: All routes learned through RIP version 6 (which enables the sharing of routes through IPv6 networks) • BGP: All routes learned through BGP. For more information, see "BGP" on page 2187. • OSPF: All routes learned through OSPF. For more information, see "OSPF" on page 2146. • OSPF6: All routes learned through OSPF version 6 (which enables the sharing of routes through IPv6 networks) • IS-IS: All routes learned through IS-IS. For more information, see "IS-IS" on page 2224. • HA: RIP, OSPF, and BGP routes synchronized between the primary unit and the subordinate units of a high availability (HA) cluster. HA routes are maintained on subordinate units and are visible only if you're viewing the router monitor from a virtual domain that is configured as a subordinate virtual domain in a virtual cluster. <p>For more information about HA routing synchronization, see the FortiOS High Availability Handbook.</p>

Field	Description
Subtype	<p>If applicable, the subtype classification assigned to OSPF routes.</p> <p>An empty string implies an intra-area route. The destination is in an area that the FortiGate is connected to.</p> <ul style="list-style-type: none"> • OSPF inter area: The destination is in the OSPF AS, but FortiGate isn't connected to that area. • External 1: The destination is outside the OSPF AS. This is known as OSPF E1 type. The metric of a redistributed route is calculated by adding the external cost and the OSPF cost together. • External 2: The destination is outside the OSPF AS. This is known as OSPF E2 type. In this case, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. • OSPF NSSA 1: Same as External 1, but the route was received through a not-so-stubby area (NSSA) • OSPF NSSA 2: Same as External 2, but the route was received through a not-so-stubby area <p>For more information about OSPF subtypes, see "OSPF" on page 2146.</p>
Network	The IP addresses and network masks of destination networks that the FortiGate can reach.
Gateway IP	The IP addresses of gateways to the destination networks.
Interfaces	The interface through which packets are forwarded to the gateway of the destination network.
Up Time	The total accumulated amount of time that a route learned through RIP, OSPF, or BGP has been reachable.
Distance	<p>The administrative distance associated with the route. A value of 0 means the route is preferable compared to other routes to the same destination, and the FortiGate may routinely use the route to communicate with neighboring routers and access servers.</p> <p>Modifying this distance for dynamic routes is route distribution. See "BGP" on page 2187.</p>

Field	Description
Metric	<p>The metric associated with the route type. The metric of a route influences how the FortiGate dynamically adds it to the routing table. The following are types of metrics and the protocols they are applied to:</p> <p>Hop count: Routes learned through RIP</p> <p>Relative cost: Routes learned through OSPF</p> <p>Multi-Exit Discriminator (MED): Routes learned through BGP. However, several attributes in addition to MED determine the best path to a destination network. For more information about BGP attributes, see "BGP" on page 2187. By default, the MED value associated with a BGP route is zero. However, the MED value can be modified dynamically. If the value was changed from the default, the Metric column displays a non-zero value.</p> <p>This field isn't displayed when IP version 6 is selected.</p>

Copying DSCP value in GRE tunnels

You can enable an option to allow copying of the DSCP (Differentiated services code point) value in GRE tunnels. This feature enables the keeping of the DSCP marking in the packets after encapsulation for going through GRE tunnels.

To enable DSCP copying - CLI:

```
config system gre-tunnel
  edit <name>
    set dscp-copying enable
  next
end
```

Configuring the maximum number of IP route cache entries

To configure the maximum number of route cache entries - CLI:

```
config system global
  set max-route-cache-size <number of cache entries>
end
```

where <number of cache entries> is in the range 0 to 2147483647

Unsetting the field causes the value to be set to the kernel-calculated default:

```
config system global
  unset max-route-cache-size
end
```

Viewing the routing table in the CLI

You can easily view the static routing table in the CLI. You can view the static routing table, just as in the GUI, or you can view the full routing table.

When you view the list of static routes using the `get router static` CLI command, the configured static routes are displayed. When you view the routing table using the `get router info routing-table all` CLI command, it's the entire routing table information that's displayed, including configured and learned routes of all types. The two commands show different information in different formats.

If VDOMs are enabled on the FortiGate, all routing-related CLI commands must be performed within a VDOM and not in the global context.

To view the routing table - CLI:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

S* 0.0.0.0/0 [10/0] via 192.168.183.254, port2
S 1.0.0.0/8 [10/0] via 192.168.183.254, port2
S 2.0.0.0/8 [10/0] via 192.168.183.254, port2
C 10.142.0.0/23 is directly connected, port3
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
C 192.168.182.0/23 is directly connected, port2
```

Examining an entry:

```
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

Value	Description
B	BGP. The routing protocol used.
10.160.0.0/23	The destination of this route, including netmask.
[20/0]	20 indicates an administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF.
10.142.0.74	The gateway or next hop.
port3	The interface that the route uses.
2d18h02m	The age of the route (in this example, it's almost three days old).

To view the kernel routing table - CLI:

```
# get router info kernel

tab=254 vf=0 scope=253 type=1 proto=2 prio=0 0.0.0.0/0.0.0.0/0->10.11.201.0/24
pref=10.11.201.4 gwy=0.0.0.0 dev=5(external1)
```

```
tab=254 vf=0 scope=253 type=1 proto=2 prio=0 0.0.0.0/0.0.0.0/0->172.20.120.0/24
pref=172.20.120.146 gwy=0.0.0.0 dev=6(internal)
```

The parts of the routing table entry are:

Value	Description
tab	Table number: This will be either 254 (unicast) or 255 (multicast).
vf	Virtual domain of the firewall: This is the VDOM index number. If VDOMs aren't enabled, this number is 0.
type	Type of routing connection: Valid values include: 0 - unspecific 1 - unicast 2 - local 3 - broadcast 4 - anycast 5 - multicast 6 - blackhole 7 - unreachable 8 - prohibited
proto	Type of installation: This indicates where the route came from. Valid values include: 0 - unspecific 2 - kernel 11 - ZebOS routing module 14 - FortiOS 15 - HA 16 - authentication based 17 - HA1
prio	Priority of the route. Lower priorities are preferred.
